2000	Finland	Computer	1500
2000	Finland	Phone	100
2000	Finland	NULL	1600
2000	India	Calculator	150
2000	India	Computer	1200

Using `LIMIT` with `ROLLUP` may produce results that are more difficult to interpret, because you have less context for understanding the super-aggregate rows.

The `NULL` indicators in each super-aggregate row are produced when the row is sent to the client. The server looks at the columns named in the `GROUP BY` clause following the leftmost one that has changed value. For any column in the result set with a name that is a lexical match to any of those names, its value is set to `NULL`. (If you specify grouping columns by column number, the server identifies which columns to set to `NULL` by number.)

Because the `NULL` values in the super-aggregate rows are placed into the result set at such a late stage in query processing, you cannot test them as `NULL` values within the query itself. For example, you cannot add `HAVING product IS NULL` to the query to eliminate from the output all but the super-aggregate rows.

On the other hand, the `NULL` values do appear as `NULL` on the client side and can be tested as such using any MySQL client programming interface.

12.11.3. GROUP BY and HAVING with Hidden Fields

MySQL extends the use of `GROUP BY` so that you can use non-aggregated columns or calculations in the `SELECT` list that do not appear in the `GROUP BY` clause. You can use this feature to get better performance by avoiding unnecessary column sorting and grouping. For example, you do not need to group on `customer.name` in the following query:

```
SELECT order.custid, customer.name, MAX(payments)
FROM order, customer
WHERE order.custid = customer.custid
GROUP BY order.custid;
```

In standard SQL, you would have to add `customer.name` to the `GROUP BY` clause. In MySQL, the name is redundant.

Do *not* use this feature if the columns you omit from the `GROUP BY` part are not constant in the group. The server is free to return any value from the group, so the results are indeterminate unless all values are the same.

A similar MySQL extension applies to the `HAVING` clause. The SQL standard does not allow the `HAVING` clause to name any column that is not found in the `GROUP BY` clause if it is not enclosed in an aggregate function. MySQL allows the use of such columns to simplify calculations. This extension assumes that the non-grouped columns will have the same group-wise values. Otherwise, the result is indeterminate.

If the `ONLY_FULL_GROUP_BY` SQL mode is enabled, the MySQL extension to `GROUP BY` does not apply. That is, columns not named in the `GROUP BY` clause cannot be used in the `SELECT` list or `HAVING` clause if not used in an aggregate function.

The select list extension also applies to `ORDER BY`. That is, you can use non-aggregated columns or calculations in the `ORDER BY` clause that do not appear in the `GROUP BY` clause. This extension does not apply if the `ONLY_FULL_GROUP_BY` SQL mode is enabled.

In some cases, you can use `MIN()` and `MAX()` to obtain a specific column value even if it isn't unique. The following gives the value of `column` from the row containing the smallest value in the `sort` column:

```
SUBSTR(MIN(CONCAT(RPAD(sort,6,' '),column)),7)
```

See [Section 3.6.4, “The Rows Holding the Group-wise Maximum of a Certain Field”](#).

Note that if you are trying to follow standard SQL, you can't use expressions in `GROUP BY` clauses. You can work around this limitation by using an alias for the expression:

```
SELECT id, FLOOR(value/100) AS val
FROM tbl_name
GROUP BY id, val;
```

MySQL does allow expressions in `GROUP BY` clauses. For example:

```
SELECT id, FLOOR(value/100)
FROM tbl_name
GROUP BY id, FLOOR(value/100);
```

Chapter 13. SQL Statement Syntax

This chapter describes the syntax for most of the SQL statements supported by MySQL. Additional statement descriptions can be found in the following chapters:

- The `EXPLAIN` statement is discussed in [Chapter 7, Optimization](#).
- Statements for writing stored routines are covered in [Chapter 18, Stored Procedures and Functions](#).
- Statements for writing triggers are covered in [Chapter 19, Triggers](#).
- View-related statements are covered in [Chapter 21, Views](#).
- Statements for scheduling events are covered in [Chapter 20, Event Scheduler](#).

13.1. Data Definition Statements

13.1.1. ALTER DATABASE Syntax

```
ALTER {DATABASE | SCHEMA} [db_name]
    alter_specification [alter_specification] ...

alter_specification:
    [DEFAULT] CHARACTER SET charset_name
    | [DEFAULT] COLLATE collation_name
```

`ALTER DATABASE` enables you to change the overall characteristics of a database. These characteristics are stored in the `db.opt` file in the database directory. To use `ALTER DATABASE`, you need the `ALTER` privilege on the database. `ALTER SCHEMA` is a synonym for `ALTER DATABASE`.

The `CHARACTER SET` clause changes the default database character set. The `COLLATE` clause changes the default database collation. [Chapter 10, Character Set Support](#), discusses character set and collation names.

The database name can be omitted, in which case the statement applies to the default database.

13.1.2. ALTER TABLE Syntax

```
ALTER [IGNORE] TABLE tbl_name
    alter_specification [, alter_specification] ...

alter_specification:
    ADD [COLUMN] column_definition [FIRST | AFTER col_name ]
    ADD [COLUMN] (column_definition,...)
    ADD {INDEX|KEY} [index_name] [index_type] (index_col_name,...)
    ADD [CONSTRAINT [symbol]]
        PRIMARY KEY [index_type] (index_col_name,...)
    ADD [CONSTRAINT [symbol]]
        UNIQUE [INDEX|KEY] [index_name] [index_type] (index_col_name,...)
    ADD FULLTEXT [INDEX|KEY] [index_name] (index_col_name,...)
        [WITH PARSER parser_name]
    ADD SPATIAL [INDEX|KEY] [index_name] (index_col_name,...)
    ADD [CONSTRAINT [symbol]]
        FOREIGN KEY [index_name] (index_col_name,...)
            [reference_definition]
    ALTER [COLUMN] col_name {SET DEFAULT literal | DROP DEFAULT}
    CHANGE [COLUMN] old_col_name column_definition
        [FIRST|AFTER col_name]
    MODIFY [COLUMN] column_definition [FIRST | AFTER col_name]
    DROP [COLUMN] col_name
    DROP PRIMARY KEY
```

```

DROP {INDEX|KEY} index_name
DROP FOREIGN KEY fk_symbol
DISABLE KEYS
ENABLE KEYS
RENAME [TO] new_tbl_name
ORDER BY col_name
CONVERT TO CHARACTER SET charset_name [COLLATE collation_name]
[DEFAULT] CHARACTER SET charset_name [COLLATE collation_name]
DISCARD TABLESPACE
IMPORT TABLESPACE
 ...
PARTITION BY partition_options
ADD PARTITION (partition_definition)
DROP PARTITION partition_names
COALESCE PARTITION number
REORGANIZE PARTITION partition_names INTO (partition_definitions)
ANALYZE PARTITION partition_names
CHECK PARTITION partition_names
OPTIMIZE PARTITION partition_names
REBUILD PARTITION partition_names
REPAIR PARTITION partition_names
REMOVE PARTITIONING

index_col_name:
  col_name [(length)] [ASC | DESC]

index_type:
  USING {BTREE | HASH}

```

ALTER TABLE enables you to change the structure of an existing table. For example, you can add or delete columns, create or destroy indexes, change the type of existing columns, or rename columns or the table itself. You can also change the comment for the table and type of the table.

The syntax for many of the allowable alterations is similar to clauses of the **CREATE TABLE** statement. This includes *table_option* modifications, for options such as **ENGINE**, **AUTO_INCREMENT**, and **AVG_ROW_LENGTH**. (However, **ALTER TABLE** ignores the **DATA DIRECTORY** and **INDEX DIRECTORY** table options.) [Section 13.1.7, “CREATE TABLE Syntax”](#), lists all table options. As of MySQL 5.1.11, to prevent inadvertent loss of data, **ALTER TABLE** cannot be used to change the storage engine of a table to **MERGE** or **BLACKHOLE**.

Some operations may result in warnings if attempted on a table for which the storage engine does not support the operation. These warnings can be displayed with **SHOW WARNINGS**. See [Section 13.5.4.30, “SHOW WARNINGS Syntax”](#).

In most cases, **ALTER TABLE** works by making a temporary copy of the original table. The alteration is performed on the copy, and then the original table is deleted and the new one is renamed. While **ALTER TABLE** is executing, the original table is readable by other clients. Updates and writes to the table are stalled until the new table is ready, and then are automatically redirected to the new table without any failed updates.

In some cases, no temporary table is necessary:

- If you use **ALTER TABLE *tbl_name* RENAME TO *new_tbl_name*** without any other options, MySQL simply renames any files that correspond to the table *tbl_name*. (You can also use the **RENAME TABLE** statement to rename tables. See [Section 13.1.16, “RENAME TABLE Syntax”](#).)
- **ALTER TABLE ... ADD PARTITION** creates no temporary table except for MySQL Cluster. **ADD** or **DROP** operations for **RANGE** or **LIST** partitions are immediate operations or nearly so. **ADD** or **COALESCE** operations for **HASH** or **KEY** partitions copy data between changed partitions; unless **LINEAR HASH/KEY** was used, this is much the same as creating a new table (although the operation is done partition by partition). **REORGANIZE** operations copy only changed partitions and do not touch unchanged ones.

If other cases, MySQL creates a temporary table, even if the data wouldn't strictly need to be copied

(such as when you change the name of a column). For [MyISAM](#) tables, you can speed up the index recreation operation (which is the slowest part of the alteration process) by setting the `myisam_sort_buffer_size` system variable to a high value.

- To use `ALTER TABLE`, you need `ALTER`, `INSERT`, and `CREATE` privileges for the table.
- `IGNORE` is a MySQL extension to standard SQL. It controls how `ALTER TABLE` works if there are duplicates on unique keys in the new table or if warnings occur when strict mode is enabled. If `IGNORE` is not specified, the copy is aborted and rolled back if duplicate-key errors occur. If `IGNORE` is specified, only the first row is used of rows with duplicates on a unique key, The other conflicting rows are deleted. Incorrect values are truncated to the closest matching acceptable value.
- You can issue multiple `ADD`, `ALTER`, `DROP`, and `CHANGE` clauses in a single `ALTER TABLE` statement, separated by commas. This is a MySQL extension to standard SQL, which allows only one of each clause per `ALTER TABLE` statement. For example, to drop multiple columns in a single statement, do this:

```
ALTER TABLE t2 DROP COLUMN c, DROP COLUMN d;
```

- `CHANGE col_name`, `DROP col_name`, and `DROP INDEX` are MySQL extensions to standard SQL.
- `MODIFY` is an Oracle extension to `ALTER TABLE`.
- The word `COLUMN` is optional and can be omitted.
- `column_definition` clauses use the same syntax for `ADD` and `CHANGE` as for `CREATE TABLE`. Note that this syntax includes the column name, not just its data type. See [Section 13.1.7](#), “`CREATE TABLE Syntax`”.
- You can rename a column using a `CHANGE old_col_name column_definition` clause. To do so, specify the old and new column names and the type that the column currently has. For example, to rename an `INTEGER` column from `a` to `b`, you can do this:

```
ALTER TABLE t1 CHANGE a b INTEGER;
```

If you want to change a column's type but not the name, `CHANGE` syntax still requires an old and new column name, even if they are the same. For example:

```
ALTER TABLE t1 CHANGE b b BIGINT NOT NULL;
```

You can also use `MODIFY` to change a column's type without renaming it:

```
ALTER TABLE t1 MODIFY b BIGINT NOT NULL;
```

- If you use `CHANGE` or `MODIFY` to shorten a column for which an index exists on the column, and the resulting column length is less than the index length, MySQL shortens the index automatically.
- When you change a data type using `CHANGE` or `MODIFY`, MySQL tries to convert existing column values to the new type as well as possible.
- To add a column at a specific position within a table row, use `FIRST` or `AFTER col_name`. The default is to add the column last. You can also use `FIRST` and `AFTER` in `CHANGE` or `MODIFY` operations.
- `ALTER ... SET DEFAULT` or `ALTER ... DROP DEFAULT` specify a new default value for a

column or remove the old default value, respectively. If the old default is removed and the column can be `NULL`, the new default is `NULL`. If the column cannot be `NULL`, MySQL assigns a default value, as described in [Section 11.1.4, “Data Type Default Values”](#).

- `DROP INDEX` removes an index. This is a MySQL extension to standard SQL. See [Section 13.1.11, “DROP INDEX Syntax”](#).
- If columns are dropped from a table, the columns are also removed from any index of which they are a part. If all columns that make up an index are dropped, the index is dropped as well.
- If a table contains only one column, the column cannot be dropped. If what you intend is to remove the table, use `DROP TABLE` instead.
- `DROP PRIMARY KEY` drops the primary index. *Note:* In older versions of MySQL, if no primary index existed, `DROP PRIMARY KEY` would drop the first `UNIQUE` index in the table. This is not the case in MySQL 5.1, where trying to use `DROP PRIMARY KEY` on a table with no primary key results in an error.

If you add a `UNIQUE INDEX` or `PRIMARY KEY` to a table, it is stored before any non-unique index so that MySQL can detect duplicate keys as early as possible.

- Some storage engines allow you to specify an index type when creating an index. The syntax for the *index_type* specifier is `USING type_name`. Before MySQL 5.1.10, `USING` can be given only before the index column list. As of 5.1.10, the preferred position is after the column list. Use of the option before the column list will no longer be recognized as of MySQL 5.3.
- `ORDER BY` enables you to create the new table with the rows in a specific order. Note that the table does not remain in this order after inserts and deletes. This option is useful primarily when you know that you are mostly to query the rows in a certain order most of the time. By using this option after major changes to the table, you might be able to get higher performance. In some cases, it might make sorting easier for MySQL if the table is in order by the column that you want to order it by later.
- If you use `ALTER TABLE` on a `MyISAM` table, all non-unique indexes are created in a separate batch (as for `REPAIR TABLE`). This should make `ALTER TABLE` much faster when you have many indexes.

This feature can be activated explicitly. `ALTER TABLE ... DISABLE KEYS` tells MySQL to stop updating non-unique indexes for a `MyISAM` table. `ALTER TABLE ... ENABLE KEYS` then should be used to re-create missing indexes. MySQL does this with a special algorithm that is much faster than inserting keys one by one, so disabling keys before performing bulk insert operations should give a considerable speedup. Using `ALTER TABLE ... DISABLE KEYS` requires the `INDEX` privilege in addition to the privileges mentioned earlier.

`ENABLE KEYS` and `DISABLE KEYS` were not supported for partitioned tables prior to MySQL 5.1.11. ([Bug#19502](#) [<http://bugs.mysql.com/19502>])

- The `FOREIGN KEY` and `REFERENCES` clauses are supported by the `InnoDB` storage engine, which implements `ADD [CONSTRAINT [symbol]] FOREIGN KEY (...) REFERENCES ... (...)`. See [Section 14.5.6.4, “FOREIGN KEY Constraints”](#). For other storage engines, the clauses are parsed but ignored. The `CHECK` clause is parsed but ignored by all storage engines. See [Section 13.1.7, “CREATE TABLE Syntax”](#). The reason for accepting but ignoring syntax clauses is for compatibility, to make it easier to port code from other SQL servers, and to run applications that create tables with references. See [Section 1.9.5, “MySQL Differences from Standard SQL”](#).

You cannot add a foreign key and drop a foreign key in separate clauses of a single `ALTER TABLE` statement. You must use separate statements.

- `InnoDB` supports the use of `ALTER TABLE` to drop foreign keys:

```
ALTER TABLE tbl_name DROP FOREIGN KEY fk_symbol;
```

You cannot add a foreign key and drop a foreign key in separate clauses of a single `ALTER TABLE` statement. You must use separate statements.

For more information, see [Section 14.5.6.4, “FOREIGN KEY Constraints”](#).

- Pending `INSERT DELAYED` statements are lost if a table is write locked and `ALTER TABLE` is used to modify the table structure.
- If you want to change the table default character set and all character columns (`CHAR`, `VARCHAR`, `TEXT`) to a new character set, use a statement like this:

```
ALTER TABLE tbl_name CONVERT TO CHARACTER SET charset_name;
```

Warning: The preceding operation converts column values between the character sets. This is *not* what you want if you have a column in one character set (like `latin1`) but the stored values actually use some other, incompatible character set (like `utf8`). In this case, you have to do the following for each such column:

```
ALTER TABLE t1 CHANGE c1 c1 BLOB;
ALTER TABLE t1 CHANGE c1 c1 TEXT CHARACTER SET utf8;
```

The reason this works is that there is no conversion when you convert to or from `BLOB` columns.

If you specify `CONVERT TO CHARACTER SET binary`, the `CHAR`, `VARCHAR`, and `TEXT` columns are converted to their corresponding binary string types (`BINARY`, `VARBINARY`, `BLOB`). This means that the columns no longer will have a character set and a subsequent `CONVERT TO` operation will not apply to them.

To change only the *default* character set for a table, use this statement:

```
ALTER TABLE tbl_name DEFAULT CHARACTER SET charset_name;
```

The word `DEFAULT` is optional. The default character set is the character set that is used if you do not specify the character set for a new column which you add to a table (for example, with `ALTER TABLE ... ADD column`).

- For an `InnoDB` table that is created with its own tablespace in an `.ibd` file, that file can be discarded and imported. To discard the `.ibd` file, use this statement:

```
ALTER TABLE tbl_name DISCARD TABLESPACE;
```

This deletes the current `.ibd` file, so be sure that you have a backup first. Attempting to access the table while the tablespace file is discarded results in an error.

To import the backup `.ibd` file back into the table, copy it into the database directory, and then issue this statement:

```
ALTER TABLE tbl_name IMPORT TABLESPACE;
```

See [Section 14.5.3.1, “Using Per-Table Tablespaces”](#).

- A number of partitioning-related extensions to `ALTER TABLE` were added in MySQL 5.1.5. These can be used with partitioned tables for repartitioning, for adding, dropping, merging, and splitting partitions, and for performing partitioning maintenance.

Simply using a *partition_options* clause with `ALTER TABLE` on a partitioned table re-partitions the table according to the partitioning scheme defined by the *partition_options*. This clause always begins with `PARTITION BY`, and follows the same syntax and other rules as apply to the *partition_options* clause for `CREATE TABLE` (see [Section 13.1.7, “CREATE TABLE Syntax”](#), for more detailed information), and can also be used to partition an existing table that is not already partitioned. For example, consider a (non-partitioned) table defined as shown here:

```
CREATE TABLE t1 (
  id INT,
  year_col INT
);
```

This table can be partitioned by `HASH`, using the `id` column as the partitioning key, into 8 partitions by means of this statement:

```
ALTER TABLE t1
  PARTITION BY HASH(id)
  PARTITIONS 8;
```

The table that results from using an `ALTER TABLE ... PARTITION BY` statement must follow the same rules as one created using `CREATE TABLE ... PARTITION BY`. This includes the rules governing the relationship between any unique keys (including any primary key) that the table might have, and the column or columns used in the partitioning expression, as discussed in [Partitioning Limitations: Partitioning Keys and Unique Keys](#). The `CREATE TABLE ... PARTITION BY` rules for specifying the number of partitions also apply to `ALTER TABLE ... PARTITION BY`.

`ALTER TABLE ... PARTITION BY` became available in MySQL 5.1.6.

The *partition_definition* clause for `ALTER TABLE ADD PARTITION` supports the same options as the clause of the same name does for the `CREATE TABLE` statement clause of the same name. (See [Section 13.1.7, “CREATE TABLE Syntax”](#), for the syntax and description.) Suppose that you have the partitioned table created as shown here:

```
CREATE TABLE t1 (
  id INT,
  year_col INT
)
PARTITION BY RANGE (year_col) (
  PARTITION p0 VALUES LESS THAN (1991),
  PARTITION p1 VALUES LESS THAN (1995),
  PARTITION p2 VALUES LESS THAN (1999)
);
```

You can add a new partition `p3` to this table for storing values less than `2002` as follows:

```
ALTER TABLE t1 ADD PARTITION (PARTITION p3 VALUES LESS THAN (2002));
```

`DROP PARTITION` can be used to drop one or more `RANGE` or `LIST` partitions. This statement cannot be used with `HASH` or `KEY` partitions; instead, use `COALESCE PARTITION` (see below). Any data that was stored in the dropped partitions named in the *partition_names* list is discarded. For example, given the table `t1` defined previously, you can drop the partitions named `p0` and `p1` as shown here:

```
ALTER TABLE t1 DROP PARTITION p0, p1;
```

Note that `DROP PARTITION` does not work with tables that use the `NDB Cluster` storage engine. See [Section 16.3.1, “Management of RANGE and LIST Partitions”](#), and [Section 15.13, “Known Limitations of MySQL Cluster”](#).

`ADD PARTITION` and `DROP PARTITION` do not currently support `IF [NOT] EXISTS`. It is also not possible to rename a partition or a partitioned table. Instead, if you wish to rename a partition, you must drop and re-create the partition; if you wish to rename a partitioned table, you must instead drop all partitions, rename the table, and then add back the partitions that were dropped.

`COALESCE PARTITION` can be used with a table that is partitioned by `HASH` or `KEY` to reduce the number of partitions by *number*. Suppose that you have created table `t2` using the following definition:

```
CREATE TABLE t2 (
  name VARCHAR (30),
  started DATE
)
PARTITION BY HASH( YEAR(started) )
PARTITIONS 6;
```

You can reduce the number of partitions used by `t2` from 6 to 4 using the following statement:

```
ALTER TABLE t2 COALESCE PARTITION 2;
```

The data contained in the last *number* partitions will be merged into the remaining partitions. In this case, partitions 4 and 5 will be merged into the first 4 partitions (the partitions numbered 0, 1, 2, and 3).

To change some but not all the partitions used by a partitioned table, you can use `REORGANIZE PARTITION`. This statement can be used in several ways:

- To merge a set of partitions into a single partition. This can be done by naming several partitions in the *partition_names* list and supplying a single definition for *partition_definition*.
- To split an existing partition into several partitions. You can accomplish this by naming a single partition for *partition_names* and providing multiple *partition_definitions*.
- To change the ranges for a subset of partitions defined using `VALUES LESS THAN` or the value lists for a subset of partitions defined using `VALUES IN`.

Note: For partitions that have not been explicitly named, MySQL automatically provides the default names `p0`, `p1`, `p2`, and so on. As of MySQL 5.1.7, the same is true with regard to subpartitions.

For more detailed information about and examples of `ALTER TABLE ... REORGANIZE PARTITION` statements, see [Section 16.3, “Partition Management”](#).

- Several additional clauses provide partition maintenance and repair functionality analogous to that implemented for non-partitioned tables by statements such as `CHECK TABLE` and `REPAIR TABLE` (which are *not* supported for partitioned tables). These include `ANALYZE PARTITION`, `CHECK PARTITION`, `OPTIMIZE PARTITION`, `REBUILD PARTITION`, and `REPAIR PARTITION`. Each of these options takes a *partition_names* clause consisting of one or more names of partitions, separated by commas. The partitions must already exist in the table to be altered. For more information, and for examples of these, see [Section 16.3.3, “Maintenance of Partitions”](#).
- `REMOVE PARTITIONING` was introduced in MySQL 5.1.8 for the purpose of removing a table's partitioning without otherwise affecting the table or its data. (Previously, this was done using the `ENGINE` option.) This option can be combined with other `ALTER TABLE` options such as those used to add, drop, or rename drop columns or indexes.

In MySQL 5.1.7 and earlier, using the `ENGINE` option with `ALTER TABLE` caused any partitioning

that a table might have had to be removed. Beginning with MySQL 5.1.8, this option merely changes the storage engine used by the table and no longer affects partitioning in any way.

With the `mysql_info()` C API function, you can find out how many rows were copied, and (when `IGNORE` is used) how many rows were deleted due to duplication of unique key values. See [Section 24.2.3.34](#), “`mysql_info()`”.

Here are some examples that show uses of `ALTER TABLE`. Begin with a table `t1` that is created as shown here:

```
CREATE TABLE t1 (a INTEGER,b CHAR(10));
```

To rename the table from `t1` to `t2`:

```
ALTER TABLE t1 RENAME t2;
```

To change column `a` from `INTEGER` to `TINYINT NOT NULL` (leaving the name the same), and to change column `b` from `CHAR(10)` to `CHAR(20)` as well as renaming it from `b` to `c`:

```
ALTER TABLE t2 MODIFY a TINYINT NOT NULL, CHANGE b c CHAR(20);
```

To add a new `TIMESTAMP` column named `d`:

```
ALTER TABLE t2 ADD d TIMESTAMP;
```

To add indexes on column `d` and on column `a`:

```
ALTER TABLE t2 ADD INDEX (d), ADD INDEX (a);
```

To remove column `c`:

```
ALTER TABLE t2 DROP COLUMN c;
```

To add a new `AUTO_INCREMENT` integer column named `c`:

```
ALTER TABLE t2 ADD c INT UNSIGNED NOT NULL AUTO_INCREMENT,  
ADD PRIMARY KEY (c);
```

Note that we indexed `c` (as a `PRIMARY KEY`), because `AUTO_INCREMENT` columns must be indexed, and also that we declare `c` as `NOT NULL`, because primary key columns cannot be `NULL`.

When you add an `AUTO_INCREMENT` column, column values are filled in with sequence numbers for you automatically. For `MyISAM` tables, you can set the first sequence number by executing `SET INSERT_ID=value` before `ALTER TABLE` or by using the `AUTO_INCREMENT=value` table option. See [Section 13.5.3](#), “`SET Syntax`”.

You can use the `ALTER TABLE ... AUTO_INCREMENT=value` table option for `InnoDB` tables to set the sequence number for new rows if the value is greater than the maximum value in the `AUTO_INCREMENT` column. *If the value is less than the current maximum value in the column, no error message is given and the current sequence value is not changed.*

With `MyISAM` tables, if you do not change the `AUTO_INCREMENT` column, the sequence number is not affected. If you drop an `AUTO_INCREMENT` column and then add another `AUTO_INCREMENT` column, the numbers are resequenced beginning with 1.

When replication is used, adding an `AUTO_INCREMENT` column to a table might not produce the same ordering of the rows on the slave and the master. This occurs because the order in which the rows are numbered depends on the specific storage engine used for the table and the order in which the rows were inserted. If it is important to have the same order on the master and slave, the rows must be ordered before assigning an `AUTO_INCREMENT` number. Assuming that you want to add an `AUTO_INCREMENT` column to the table `t1`, the following statements produce a new table `t2` identical to `t1` but with an `AUTO_INCREMENT` column:

```
CREATE TABLE t2 (id INT AUTO_INCREMENT PRIMARY KEY)
SELECT * FROM t1 ORDER BY col1, col2;
```

This assumes that the table `t1` has columns `col1` and `col2`.

This set of statements will also produce a new table `t2` identical to `t1`, with the addition of an `AUTO_INCREMENT` column:

```
CREATE TABLE t2 LIKE t1;
ALTER TABLE T2 ADD id INT AUTO_INCREMENT PRIMARY KEY;
INSERT INTO t2 SELECT * FROM t1 ORDER BY col1, col2;
```

Important: To guarantee the same ordering on both master and slave, *all* columns of `t1` must be referenced in the `ORDER BY` clause.

Regardless of the method used to create and populate the copy having the `AUTO_INCREMENT` column, the final step is to drop the original table and then rename the copy:

```
DROP t1;
ALTER TABLE t2 RENAME t1;
```

See also [Section A.7.1, “Problems with ALTER TABLE”](#).

13.1.3. ALTER LOGFILE GROUP Syntax

```
ALTER LOGFILE GROUP logfile_group
ADD UNDOFILE 'file'
INITIAL_SIZE [=] size
ENGINE [=] engine
```

This statement adds an `UNDO` file named `'file'` to an existing logfile group `logfile_group`. An `ALTER LOGFILE GROUP` statement has one and only one `ADD UNDOFILE` clause. No `DROP UNDOFILE` clause is supported.

The `INITIAL_SIZE` parameter sets the `UNDO` file's initial size in bytes. You may optionally follow `size` with a one-letter abbreviation for an order of magnitude, similar to those used in `my.cnf`. Generally, this is one of the letters `M` (for megabytes) or `G` (for gigabytes).

The `ENGINE` parameter (required) determines the storage engine which is used by this logfile group, with `engine` being the name of the storage engine. In MySQL 5.1, the only accepted values for `engine` are `NDB` and `NDBCLUSTER`.

Here is an example, which assumes that the logfile group `lg_3` has already been created using `CREATE LOGFILE GROUP` (see [Section 13.1.8, “CREATE LOGFILE GROUP Syntax”](#)):

```
ALTER LOGFILE GROUP lg_3
ADD UNDOFILE 'undo_10.dat'
INITIAL_SIZE=32M
ENGINE=NDB;
```

When `ALTER LOGFILE GROUP` is used with `ENGINE = NDB`, an `UNDO` logfile is created on each

Cluster data node. You can verify that the `UNDO` files were created and obtain information about them by querying the `INFORMATION_SCHEMA.FILES` table. For example:

```
mysql> SELECT FILE_NAME, LOGFILE_GROUP_NUMBER, EXTRA
-> FROM INFORMATION_SCHEMA.FILES
-> WHERE LOGFILE_GROUP_NAME = 'lg_3';
```

FILE_NAME	LOGFILE_GROUP_NUMBER	EXTRA
newdata.dat	0	CLUSTER_NODE=3
newdata.dat	0	CLUSTER_NODE=4
undo_10.dat	11	CLUSTER_NODE=3
undo_10.dat	11	CLUSTER_NODE=4

4 rows in set (0.01 sec)

(See [Section 22.21](#), “The `INFORMATION_SCHEMA.FILES` Table”.)

`ALTER LOGFILE GROUP` was added in MySQL 5.1.6. In MySQL 5.1, it is useful only with Disk Data storage for MySQL Cluster. See [Section 15.11](#), “MySQL Cluster Disk Data Storage”.

13.1.4. ALTER TABLESPACE Syntax

```
ALTER TABLESPACE tablespace
  ADD DATAFILE 'file'
  INITIAL_SIZE [=] size
  ENGINE [=] engine

ALTER TABLESPACE tablespace
  DROP DATAFILE 'file'
  ENGINE [=] engine
```

This statement can be used either to add a new datafile, or to drop a datafile from a tablespace.

The `ADD DATAFILE` variant requires that you specify an initial size using an `INITIAL_SIZE` clause, where *size* is measured in bytes. You may optionally follow an integer value with a one-letter abbreviation for an order of magnitude, similar to those used in `my.cnf`. Generally, this is one of the letters `M` (for megabytes) or `G` (for gigabytes).

Once a datafile has been created, its size cannot be changed; however, you can add more datafiles to the tablespace using additional `ALTER TABLESPACE ... ADD DATAFILE` statements.

Using `DROP DATAFILE` with `ALTER TABLESPACE` drops a datafile '*file*' from the tablespace. This file must already have been added to the tablespace using `CREATE TABLESPACE` or `ALTER TABLESPACE`; otherwise an error will result.

Both `ALTER TABLESPACE ... ADD DATAFILE` and `ALTER TABLESPACE ... DROP DATAFILE` require an `ENGINE` clause which specifies the storage engine used by the tablespace. In MySQL 5.1, the only accepted values for *engine* are `NDB` and `NDBCLUSTER`.

When `ALTER TABLESPACE ... ADD DATAFILE` is used with `ENGINE = NDB`, a datafile is created on each Cluster data node. You can verify that the datafiles were created and obtain information about them by querying the `INFORMATION_SCHEMA.FILES` table. For example, the following query shows all datafiles belonging to the tablespace named `newts`:

```
mysql> SELECT LOGFILE_GROUP_NAME, FILE_NAME, EXTRA
-> FROM INFORMATION_SCHEMA.FILES
-> WHERE TABLESPACE_NAME = 'newts' AND FILE_TYPE = 'DATAFILE';
```

LOGFILE_GROUP_NAME	FILE_NAME	EXTRA
lg_3	newdata.dat	CLUSTER_NODE=3
lg_3	newdata.dat	CLUSTER_NODE=4
lg_3	newdata2.dat	CLUSTER_NODE=3
lg_3	newdata2.dat	CLUSTER_NODE=4

```
2 rows in set (0.03 sec)
```

See [Section 22.21](#), “The `INFORMATION_SCHEMA FILES` Table”.

`ALTER TABLESPACE` was added in MySQL 5.1.6. In MySQL 5.1, it is useful only with Disk Data storage for MySQL Cluster. See [Section 15.11](#), “MySQL Cluster Disk Data Storage”.

13.1.5. CREATE DATABASE Syntax

```
CREATE {DATABASE | SCHEMA} [IF NOT EXISTS] db_name
    [create_specification [create_specification] ...]

create_specification:
    [DEFAULT] CHARACTER SET charset_name
    | [DEFAULT] COLLATE collation_name
```

`CREATE DATABASE` creates a database with the given name. To use this statement, you need the `CREATE` privilege for the database. `CREATE SCHEMA` is a synonym for `CREATE DATABASE`.

An error occurs if the database exists and you did not specify `IF NOT EXISTS`.

create_specification options specify database characteristics. Database characteristics are stored in the `db.opt` file in the database directory. The `CHARACTER SET` clause specifies the default database character set. The `COLLATE` clause specifies the default database collation. [Chapter 10, Character Set Support](#), discusses character set and collation names.

A database in MySQL is implemented as a directory containing files that correspond to tables in the database. Because there are no tables in a database when it is initially created, the `CREATE DATABASE` statement creates only a directory under the MySQL data directory and the `db.opt` file. Rules for allowable database names are given in [Section 9.2](#), “Database, Table, Index, Column, and Alias Names”. If a database name contains special characters, the name for the database directory contains encoded versions of those characters as described in [Section 9.2.3](#), “Mapping of Identifiers to Filenames”.

If you manually create a directory under the data directory (for example, with `mkdir`), the server considers it a database directory and it shows up in the output of `SHOW DATABASES`.

You can also use the `mysqladmin` program to create databases. See [Section 8.8](#), “`mysqladmin` — Client for Administering a MySQL Server”.

13.1.6. CREATE INDEX Syntax

```
CREATE [UNIQUE|FULLTEXT|SPATIAL] INDEX index_name
    [index_type]
    ON tbl_name (index_col_name,...)
    [index_option ...]

index_col_name:
    col_name [(length)] [ASC | DESC]

index_type:
    USING {BTREE | HASH}

index_option:
    KEY_BLOCK_SIZE value
    | index_type
    | WITH PARSER parser_name
```

`CREATE INDEX` is mapped to an `ALTER TABLE` statement to create indexes. See [Section 13.1.2](#), “`ALTER TABLE Syntax`”. For more information about indexes, see [Section 7.4.5](#), “How MySQL Uses Indexes”.

Normally, you create all indexes on a table at the time the table itself is created with `CREATE TABLE`.

See [Section 13.1.7, “CREATE TABLE Syntax”](#). `CREATE INDEX` enables you to add indexes to existing tables.

A column list of the form `(col1,col2,...)` creates a multiple-column index. Index values are formed by concatenating the values of the given columns.

For `CHAR`, `VARCHAR`, `BINARY`, and `VARBINARY` columns, indexes can be created that use only the leading part of column values, using `col_name(length)` syntax to specify an index prefix length. `BLOB` and `TEXT` columns also can be indexed, but a prefix length *must* be given. Prefix lengths are given in characters for non-binary string types and in bytes for binary string types. That is, index entries consist of the first `length` characters of each column value for `CHAR`, `VARCHAR`, and `TEXT` columns, and the first `length` bytes of each column value for `BINARY`, `VARBINARY`, and `BLOB` columns.

The statement shown here creates an index using the first 10 characters of the `name` column:

```
CREATE INDEX part_of_name ON customer (name(10));
```

If names in the column usually differ in the first 10 characters, this index should not be much slower than an index created from the entire `name` column. Also, using partial columns for indexes can make the index file much smaller, which could save a lot of disk space and might also speed up `INSERT` operations.

Prefixes can be up to 1000 bytes long (767 bytes for `InnoDB` tables). Note that prefix limits are measured in bytes, whereas the prefix length in `CREATE INDEX` statements is interpreted as number of characters for non-binary data types (`CHAR`, `VARCHAR`, `TEXT`). Take this into account when specifying a prefix length for a column that uses a multi-byte character set.

A `UNIQUE` index creates a constraint such that all values in the index must be distinct. An error occurs if you try to add a new row with a key value that matches an existing row. For all engines, a `UNIQUE` index allows multiple `NULL` values for columns that can contain `NULL`.

`FULLTEXT` indexes are supported only for `MyISAM` tables and can include only `CHAR`, `VARCHAR`, and `TEXT` columns. Indexing always happens over the entire column; partial indexing is not supported and any prefix length is ignored if specified. See [Section 12.7, “Full-Text Search Functions”](#), for details of operation.

`SPATIAL` indexes are supported only for `MyISAM` tables and can include only spatial columns that are defined as `NOT NULL`. [Chapter 17, *Spatial Extensions*](#), describes the spatial data types.

In MySQL 5.1:

- You can add an index on a column that can have `NULL` values only if you are using the `MyISAM`, `InnoDB`, or `MEMORY` storage engine.
- You can add an index on a `BLOB` or `TEXT` column only if you are using the `MyISAM`, or `InnoDB` storage engine.

An `index_col_name` specification can end with `ASC` or `DESC`. These keywords are allowed for future extensions for specifying ascending or descending index value storage. Currently, they are parsed but ignored; index values are always stored in ascending order.

Following the index column list, index options can be given. An `index_option` value can be any of the following:

- `KEY_BLOCK_SIZE value`

This option provides a hint to the storage engine about the size to use for index key blocks. The en-

engine is allowed to change the value if necessary. A value of 0 indicates that the default value should be used. `KEY_BLOCK_SIZE` was added in MySQL 5.1.10.

- `index_type`

Some storage engines allow you to specify an index type when creating an index. The allowable index type values supported by different storage engines are shown in the following table. Where multiple index types are listed, the first one is the default when no index type specifier is given.

Storage Engine	Allowable Index Types
MyISAM	BTREE
InnoDB	BTREE
MEMORY/HEAP	HASH, BTREE

If you specify an index type that is not legal for a given storage engine, but there is another index type available that the engine can use without affecting query results, the engine uses the available type.

Examples:

```
CREATE TABLE lookup (id INT) ENGINE = MEMORY;
CREATE INDEX id_index USING BTREE ON lookup (id);
```

`TYPE type_name` is recognized as a synonym for `USING type_name`. However, `USING` is the preferred form.

Note: Before MySQL 5.1.10, this option can be given only before the `ON tbl_name` clause. Use of the option in this position is deprecated as of 5.1.10 and will no longer be supported from MySQL 5.3 on.

- `WITH PARSER parser_name`

This option can be used only with `FULLTEXT` indexes. It associates a parser plugin with the index if full-text indexing and searching operations need special handling. See [Section 26.2, “The MySQL Plugin Interface”](#), for details on creating plugins.

13.1.7. CREATE TABLE Syntax

```
CREATE [TEMPORARY] TABLE [IF NOT EXISTS] tbl_name
  (create_definition,...)
  [table_option ...]
  [partition_options]
```

Or:

```
CREATE [TEMPORARY] TABLE [IF NOT EXISTS] tbl_name
  [(create_definition,...)]
  [table_option ...]
  [partition_options]
  select_statement
```

Or:

```
CREATE [TEMPORARY] TABLE [IF NOT EXISTS] tbl_name
  { LIKE old_tbl_name | (LIKE old_tbl_name) }
```

```

create_definition:

```

CREATE TABLE creates a table with the given name. You must have the **CREATE** privilege for the table.

Rules for allowable table names are given in [Section 9.2, “Database, Table, Index, Column, and Alias Names”](#). By default, the table is created in the default database. An error occurs if the table exists, if there is no default database, or if the database does not exist.

The table name can be specified as *db_name.tbl_name* to create the table in a specific database. This works regardless of whether there is a default database, assuming that the database exists. If you use quoted identifiers, quote the database and table names separately. For example, write ``mydb`.`mytbl``, not ``mydb.mytbl``.

You can use the **TEMPORARY** keyword when creating a table. A **TEMPORARY** table is visible only to the current connection, and is dropped automatically when the connection is closed. This means that two different connections can use the same temporary table name without conflicting with each other or with

an existing non-`TEMPORARY` table of the same name. (The existing table is hidden until the temporary table is dropped.) To create temporary tables, you must have the `CREATE TEMPORARY TABLES` privilege.

The keywords `IF NOT EXISTS` prevent an error from occurring if the table exists. However, there is no verification that the existing table has a structure identical to that indicated by the `CREATE TABLE` statement. *Note:* If you use `IF NOT EXISTS` in a `CREATE TABLE . . . SELECT` statement, any rows selected by the `SELECT` part are inserted regardless of whether the table already exists.

MySQL represents each table by an `.frm` table format (definition) file in the database directory. The storage engine for the table might create other files as well. In the case of `MyISAM` tables, the storage engine creates data and index files. Thus, for each `MyISAM` table `tbl_name`, there are three disk files:

File	Purpose
<code>tbl_name.frm</code>	Table format (definition) file
<code>tbl_name.MYD</code>	Data file
<code>tbl_name.MYI</code>	Index file

Chapter 14, *Storage Engines and Table Types*, describes what files each storage engine creates to represent tables. If a table name contains special characters, the names for the table files contain encoded versions of those characters as described in Section 9.2.3, “Mapping of Identifiers to Filenames”.

`data_type` represents the data type is a column definition. `spatial_type` represents a spatial data type. For general information on the properties of data types other than the spatial types, see Chapter 11, *Data Types*. For information about spatial data types, see Chapter 17, *Spatial Extensions*.

Some attributes do not apply to all data types. `AUTO_INCREMENT` applies only to integer types. `DEFAULT` does not apply to the `BLOB` or `TEXT` types.

- If neither `NULL` nor `NOT NULL` is specified, the column is treated as though `NULL` had been specified.
- An integer column can have the additional attribute `AUTO_INCREMENT`. When you insert a value of `NULL` (recommended) or `0` into an indexed `AUTO_INCREMENT` column, the column is set to the next sequence value. Typically this is `value+1`, where `value` is the largest value for the column currently in the table. `AUTO_INCREMENT` sequences begin with `1`.

To retrieve an `AUTO_INCREMENT` value after inserting a row, use the `LAST_INSERT_ID()` SQL function or the `mysql_insert_id()` C API function. See Section 12.10.3, “Information Functions”, and Section 24.2.3.36, “`mysql_insert_id()`”.

If the `NO_AUTO_VALUE_ON_ZERO` SQL mode is enabled, you can store `0` in `AUTO_INCREMENT` columns as `0` without generating a new sequence value. See Section 5.2.6, “SQL Modes”.

Note: There can be only one `AUTO_INCREMENT` column per table, it must be indexed, and it cannot have a `DEFAULT` value. An `AUTO_INCREMENT` column works properly only if it contains only positive values. Inserting a negative number is regarded as inserting a very large positive number. This is done to avoid precision problems when numbers “wrap” over from positive to negative and also to ensure that you do not accidentally get an `AUTO_INCREMENT` column that contains `0`.

For `MyISAM` tables, you can specify an `AUTO_INCREMENT` secondary column in a multiple-column key. See Section 3.6.9, “Using `AUTO_INCREMENT`”.

To make MySQL compatible with some ODBC applications, you can find the `AUTO_INCREMENT` value for the last inserted row with the following query:

```
SELECT * FROM tbl_name WHERE auto_col IS NULL
```

For information about `InnoDB` and `AUTO_INCREMENT`, see [Section 14.5.6.3, “How `AUTO_INCREMENT` Columns Work in `InnoDB`”](#).

- The attribute `SERIAL` is an alias for `BIGINT UNSIGNED NOT NULL AUTO_INCREMENT UNIQUE`.
- Character data types (`CHAR`, `VARCHAR`, `TEXT`) can include `CHARACTER SET` and `COLLATE` attributes to specify the character set and collation for the column. For details, see [Chapter 10, *Character Set Support*](#). `CHARSET` is a synonym for `CHARACTER SET`. Example:

```
CREATE TABLE t (c CHAR(20) CHARACTER SET utf8 COLLATE utf8_bin);
```

MySQL 5.1 interprets length specifications in character column definitions in characters. (Versions before MySQL 4.1 interpreted them in bytes.) Lengths for `BINARY` and `VARBINARY` are in bytes.

- The `DEFAULT` clause specifies a default value for a column. With one exception, the default value must be a constant; it cannot be a function or an expression. This means, for example, that you cannot set the default for a date column to be the value of a function such as `NOW()` or `CURRENT_DATE`. The exception is that you can specify `CURRENT_TIMESTAMP` as the default for a `TIMESTAMP` column. See [Section 11.3.1.1, “`TIMESTAMP` Properties as of MySQL 4.1”](#).

If a column definition includes no explicit `DEFAULT` value, MySQL determines the default value as described in [Section 11.1.4, “Data Type Default Values”](#).

`BLOB` and `TEXT` columns cannot be assigned a default value.

- A comment for a column can be specified with the `COMMENT` option, up to 255 characters long. The comment is displayed by the `SHOW CREATE TABLE` and `SHOW FULL COLUMNS` statements.
- `KEY` is normally a synonym for `INDEX`. The key attribute `PRIMARY KEY` can also be specified as just `KEY` when given in a column definition. This was implemented for compatibility with other database systems.
- A `UNIQUE` index creates a constraint such that all values in the index must be distinct. An error occurs if you try to add a new row with a key value that matches an existing row. For all engines, a `UNIQUE` index allows multiple `NULL` values for columns that can contain `NULL`.
- A `PRIMARY KEY` is a unique index where all key columns must be defined as `NOT NULL`. If they are not explicitly declared as `NOT NULL`, MySQL declares them so implicitly (and silently). A table can have only one `PRIMARY KEY`. If you do not have a `PRIMARY KEY` and an application asks for the `PRIMARY KEY` in your tables, MySQL returns the first `UNIQUE` index that has no `NULL` columns as the `PRIMARY KEY`.

In `InnoDB` tables, having a long `PRIMARY KEY` wastes a lot of space. (See [Section 14.5.13, “`InnoDB` Table and Index Structures”](#).)

- In the created table, a `PRIMARY KEY` is placed first, followed by all `UNIQUE` indexes, and then the non-unique indexes. This helps the MySQL optimizer to prioritize which index to use and also more quickly to detect duplicated `UNIQUE` keys.
- A `PRIMARY KEY` can be a multiple-column index. However, you cannot create a multiple-column index using the `PRIMARY KEY` key attribute in a column specification. Doing so only marks that single column as primary. You must use a separate `PRIMARY KEY(index_col_name, ...)` clause.
- If a `PRIMARY KEY` or `UNIQUE` index consists of only one column that has an integer type, you can also refer to the column as `_rowid` in `SELECT` statements.

- In MySQL, the name of a `PRIMARY KEY` is `PRIMARY`. For other indexes, if you do not assign a name, the index is assigned the same name as the first indexed column, with an optional suffix (`_2`, `_3`, ...) to make it unique. You can see index names for a table using `SHOW INDEX FROM tbl_name`. See [Section 13.5.4.17](#), “`SHOW INDEX Syntax`”.
- Some storage engines allow you to specify an index type when creating an index. The syntax for the `index_type` specifier is `USING type_name`.

Example:

```
CREATE TABLE lookup
(id INT, INDEX USING BTREE (id))
ENGINE = MEMORY;
```

Before MySQL 5.1.10, `USING` can be given only before the index column list. As of 5.1.10, the preferred position is after the column list. Use of the option before the column list will no longer be recognized as of MySQL 5.3.

`index_option` values specify additional options for an index. `USING` is one such option. For details about allowable `index_option` values, see [Section 13.1.6](#), “`CREATE INDEX Syntax`”.

For more information about indexes, see [Section 7.4.5](#), “`How MySQL Uses Indexes`”.

- In MySQL 5.1, only the `MyISAM`, `InnoDB`, and `MEMORY` storage engines support indexes on columns that can have `NULL` values. In other cases, you must declare indexed columns as `NOT NULL` or an error results.
- For `CHAR`, `VARCHAR`, `BINARY`, and `VARBINARY` columns, indexes can be created that use only the leading part of column values, using `col_name(length)` syntax to specify an index prefix length. `BLOB` and `TEXT` columns also can be indexed, but a prefix length *must* be given. Prefix lengths are given in characters for non-binary string types and in bytes for binary string types. That is, index entries consist of the first `length` characters of each column value for `CHAR`, `VARCHAR`, and `TEXT` columns, and the first `length` bytes of each column value for `BINARY`, `VARBINARY`, and `BLOB` columns. Indexing only a prefix of column values like this can make the index file much smaller. See [Section 7.4.3](#), “`Column Indexes`”.

Only the `MyISAM` and `InnoDB` storage engines support indexing on `BLOB` and `TEXT` columns. For example:

```
CREATE TABLE test (blob_col BLOB, INDEX(blob_col(10)));
```

Prefixes can be up to 1000 bytes long (767 bytes for `InnoDB` tables). Note that prefix limits are measured in bytes, whereas the prefix length in `CREATE TABLE` statements is interpreted as number of characters for non-binary data types (`CHAR`, `VARCHAR`, `TEXT`). Take this into account when specifying a prefix length for a column that uses a multi-byte character set.

- An `index_col_name` specification can end with `ASC` or `DESC`. These keywords are allowed for future extensions for specifying ascending or descending index value storage. Currently, they are parsed but ignored; index values are always stored in ascending order.
- When you use `ORDER BY` or `GROUP BY` on a `TEXT` or `BLOB` column in a `SELECT`, the server sorts values using only the initial number of bytes indicated by the `max_sort_length` system variable. See [Section 11.4.3](#), “`The BLOB and TEXT Types`”.
- You can create special `FULLTEXT` indexes, which are used for full-text searches. Only the `MyISAM` storage engine supports `FULLTEXT` indexes. They can be created only from `CHAR`, `VARCHAR`, and `TEXT` columns. Indexing always happens over the entire column; partial indexing is not supported and any prefix length is ignored if specified. See [Section 12.7](#), “`Full-Text Search Functions`”, for de-

tails of operation. A `WITH PARSER` clause can be specified as an *index_option* value to associate a parser plugin with the index if full-text indexing and searching operations need special handling. This clause is legal only for `FULLTEXT` indexes. See [Section 26.2, “The MySQL Plugin Interface”](#), for details on creating plugins.

- You can create `SPATIAL` indexes on spatial data types. Spatial types are supported only for `MyISAM` tables and indexed columns must be declared as `NOT NULL`. See [Chapter 17, *Spatial Extensions*](#).
- `InnoDB` tables support checking of foreign key constraints. See [Section 14.5, “The InnoDB Storage Engine”](#). Note that the `FOREIGN KEY` syntax in `InnoDB` is more restrictive than the syntax presented for the `CREATE TABLE` statement at the beginning of this section: The columns of the referenced table must always be explicitly named. `InnoDB` supports both `ON DELETE` and `ON UPDATE` actions on foreign keys. For the precise syntax, see [Section 14.5.6.4, “FOREIGN KEY Constraints”](#).

For other storage engines, MySQL Server parses and ignores the `FOREIGN KEY` and `REFERENCES` syntax in `CREATE TABLE` statements. The `CHECK` clause is parsed but ignored by all storage engines. See [Section 1.9.5.5, “Foreign Keys”](#).

- For `MyISAM` tables, each `NULL` column takes one bit extra, rounded up to the nearest byte. The maximum row length in bytes can be calculated as follows:

```
row length = 1
             + (sum of column lengths)
             + (number of NULL columns + delete_flag + 7)/8
             + (number of variable-length columns)
```

delete_flag is 1 for tables with static row format. Static tables use a bit in the row record for a flag that indicates whether the row has been deleted. *delete_flag* is 0 for dynamic tables because the flag is stored in the dynamic row header.

These calculations do not apply for `InnoDB` tables, for which storage size is no different for `NULL` columns than for `NOT NULL` columns.

The `TABLESPACE ... STORAGE DISK` table option is used only with `NDB Cluster` tables. It assigns the table to a Cluster Disk Data tablespace. The tablespace named *tablespace_name* must already have been created using `CREATE TABLESPACE`. This table option was introduced in MySQL 5.1.6. See [Section 15.11, “MySQL Cluster Disk Data Storage”](#).

The `ENGINE` table option specifies the storage engine for the table.

The `ENGINE` table option takes the storage engine names shown in the following table.

Storage Engine	Description
<code>ARCHIVE</code>	The archiving storage engine. See Section 14.10, “The ARCHIVE Storage Engine” .
<code>CSV</code>	Tables that store rows in comma-separated values format. See Section 14.11, “The CSV Storage Engine” .
<code>EXAMPLE</code>	An example engine. See Section 14.8, “The EXAMPLE Storage Engine” .
<code>FEDERATED</code>	Storage engine that accesses remote tables. See Section 14.9, “The FEDERATED Storage Engine” .
<code>HEAP</code>	This is a synonym for <code>MEMORY</code> .
<code>ISAM</code> (<i>OBSOLETE</i>)	Not available in MySQL 5.1. If you are upgrading to MySQL 5.1 from a previous version, you should convert any existing <code>ISAM</code> tables to <code>MyISAM</code> before performing the upgrade.

InnoDB	Transaction-safe tables with row locking and foreign keys. See Section 14.5, “The InnoDB Storage Engine” .
MEMORY	The data for this storage engine is stored only in memory. See Section 14.7, “The MEMORY (HEAP) Storage Engine” .
MERGE	A collection of MyISAM tables used as one table. Also known as MRG_MyISAM. See Section 14.6, “The MERGE Storage Engine” .
MyISAM	The binary portable storage engine that is the default storage engine used by MySQL. See Section 14.4, “The MyISAM Storage Engine” .
NDBCLUSTER	Clustered, fault-tolerant, memory-based tables. Also known as NDB. See Chapter 15, MySQL Cluster .

If a storage engine is specified that is not available, MySQL uses the default engine instead. Normally, this is `MyISAM`. For example, if a table definition includes the `ENGINE=INNODB` option but the MySQL server does not support `INNODB` tables, the table is created as a `MyISAM` table. This makes it possible to have a replication setup where you have transactional tables on the master but tables created on the slave are non-transactional (to get more speed). In MySQL 5.1, a warning occurs if the storage engine specification is not honored.

Note: The older `TYPE` option was synonymous with `ENGINE`. `TYPE` has been deprecated since MySQL 4.0 but is still supported for backwards compatibility in MySQL 5.1 (excepting MySQL 5.1.7). Since MySQL 5.1.8, it produces a warning. It is scheduled for removal in MySQL 5.2. *You should not use `TYPE` in any new applications, and you should immediately begin conversion of existing applications to use `ENGINE` instead.* (See [Section D.1.5, “Changes in release 5.1.8 \(Not released\)”](#).)

The other table options are used to optimize the behavior of the table. In most cases, you do not have to specify any of them. These options apply to all storage engines unless otherwise indicated. Options that do not apply to a given storage engine may be accepted and remembered as part of the table definition. Such options then apply if you later use `ALTER TABLE` to convert the table to use a different storage engine.

- `AUTO_INCREMENT`

The initial `AUTO_INCREMENT` value for the table. In MySQL 5.1, this works for `MyISAM`, `MEMORY`, and `InnoDB` tables. To set the first auto-increment value for engines that do not support the `AUTO_INCREMENT` table option, insert a “dummy” row with a value one less than the desired value after creating the table, and then delete the dummy row.

For engines that support the `AUTO_INCREMENT` table option in `CREATE TABLE` statements, you can also use `ALTER TABLE tbl_name AUTO_INCREMENT = N` to reset the `AUTO_INCREMENT` value.

- `AVG_ROW_LENGTH`

An approximation of the average row length for your table. You need to set this only for large tables with variable-size rows.

When you create a `MyISAM` table, MySQL uses the product of the `MAX_ROWS` and `AVG_ROW_LENGTH` options to decide how big the resulting table is. If you don't specify either option, the maximum size for a table is 65,536TB of data. (If your operating system does not support files that large, table sizes are constrained by the file size limit.) If you want to keep down the pointer sizes to make the index smaller and faster and you don't really need big files, you can decrease the default pointer size by setting the `myisam_data_pointer_size` system variable. (See [Section 5.2.3, “System Variables”](#).) If you want all your tables to be able to grow above the default limit and are willing to have your tables slightly slower and larger than necessary, you can increase the

default pointer size by setting this variable.

- `[DEFAULT] CHARACTER SET`

Specify a default character set for the table. `CHARSET` is a synonym for `CHARACTER SET`.

- `CHECKSUM`

Set this to 1 if you want MySQL to maintain a live checksum for all rows (that is, a checksum that MySQL updates automatically as the table changes). This makes the table a little slower to update, but also makes it easier to find corrupted tables. The `CHECKSUM TABLE` statement reports the checksum. (`MyISAM` only.)

- `COLLATE`

Specify a default collation for the table.

- `COMMENT`

A comment for the table, up to 60 characters long.

- `CONNECTION`

The connection string for a `FEDERATED` table. (**Note:** Older versions of MySQL used a `COMMENT` option for the connection string.)

- `DATA DIRECTORY, INDEX DIRECTORY`

By using `DATA DIRECTORY='directory'` or `INDEX DIRECTORY='directory'` you can specify where the `MyISAM` storage engine should put a table's data file and index file. The directory must be the full pathname to the directory, not a relative path.

These options work only when you are not using the `--skip-symbolic-links` option. Your operating system must also have a working, thread-safe `realpath()` call. See [Section 7.6.1.2, “Using Symbolic Links for Tables on Unix”](#), for more complete information.

- `DELAY_KEY_WRITE`

Set this to 1 if you want to delay key updates for the table until the table is closed. See the description of the `delay_key_write` system variable in [Section 5.2.3, “System Variables”](#). (`MyISAM` only.)

- `INSERT_METHOD`

If you want to insert data into a `MERGE` table, you must specify with `INSERT_METHOD` the table into which the row should be inserted. `INSERT_METHOD` is an option useful for `MERGE` tables only. Use a value of `FIRST` or `LAST` to have inserts go to the first or last table, or a value of `NO` to prevent inserts. See [Section 14.6, “The MERGE Storage Engine”](#).

- `KEY_BLOCK_SIZE`

This option provides a hint to the storage engine about the size to use for index key blocks. The engine is allowed to change the value if necessary. A value of 0 indicates that the default value should be used. Individual index definitions can specify a `KEY_BLOCK_SIZE` value of their own to override the table value. `KEY_BLOCK_SIZE` was added in MySQL 5.1.10.

- `MAX_ROWS`

The maximum number of rows you plan to store in the table. This is not a hard limit, but rather a

hint to the storage engine that the table must be able to store at least this many rows.

- `MIN_ROWS`

The minimum number of rows you plan to store in the table.

- `PACK_KEYS`

`PACK_KEYS` takes effect only with `MyISAM` tables. Set this option to 1 if you want to have smaller indexes. This usually makes updates slower and reads faster. Setting the option to 0 disables all packing of keys. Setting it to `DEFAULT` tells the storage engine to pack only long `CHAR` or `VARCHAR` columns.

If you do not use `PACK_KEYS`, the default is to pack strings, but not numbers. If you use `PACK_KEYS=1`, numbers are packed as well.

When packing binary number keys, MySQL uses prefix compression:

- Every key needs one extra byte to indicate how many bytes of the previous key are the same for the next key.
- The pointer to the row is stored in high-byte-first order directly after the key, to improve compression.

This means that if you have many equal keys on two consecutive rows, all following “same” keys usually only take two bytes (including the pointer to the row). Compare this to the ordinary case where the following keys takes `storage_size_for_key + pointer_size` (where the pointer size is usually 4). Conversely, you get a significant benefit from prefix compression only if you have many numbers that are the same. If all keys are totally different, you use one byte more per key, if the key is not a key that can have `NULL` values. (In this case, the packed key length is stored in the same byte that is used to mark if a key is `NULL`.)

- `PASSWORD`

Encrypt the `.frm` file with a password. This option does nothing in the standard MySQL version.

- `RAID_TYPE`

`RAID` support has been removed as of MySQL 5.0. For information on `RAID`, see <http://dev.mysql.com/doc/refman/4.1/en/create-table.html>.

- `ROW_FORMAT`

Defines how the rows should be stored. For `MyISAM` tables, the option value can be `FIXED` or `DYNAMIC` for static or variable-length row format. `myisampack` sets the type to `COMPRESSED`. See [Section 14.4.3, “MyISAM Table Storage Formats”](#).

For `InnoDB` tables, rows are stored in compact format (`ROW_FORMAT=COMPACT`) by default. The non-compact format used in older versions of MySQL can still be requested by specifying `ROW_FORMAT=REDUNDANT`.

- `UNION`

`UNION` is used when you want to access a collection of identical `MyISAM` tables as one. This works only with `MERGE` tables. See [Section 14.6, “The MERGE Storage Engine”](#).

You must have `SELECT`, `UPDATE`, and `DELETE` privileges for the tables you map to a `MERGE` table. (*Note:* Formerly, all tables used had to be in the same database as the `MERGE` table itself. This

restriction no longer applies.)

partition_options can be used to control partitioning of the table created with `CREATE TABLE`, and if used, must contain at a minimum a `PARTITION BY` clause. This clause contains the function that is used to determine the partition; the function returns an integer value ranging from 1 to *num*, where *num* is the number of partitions. The choices that are available for this function in MySQL 5.1 are shown in the following list.

Important: Not all options shown in the syntax for *partition_options* at the beginning of this section are available for all partitioning types. Please see the listings for the following individual types for information specific to each type, and see [Chapter 16, Partitioning](#), for more complete information about the workings of and uses for partitioning in MySQL, as well as additional examples of table creation and other statements relating to MySQL partitioning.

- `HASH(expr)`: Hashes one or more columns to create a key for placing and locating rows. *expr* is an expression using one or more table columns. This can be any legal MySQL expression (including MySQL functions) that yields a single integer value. For example, these are all valid `CREATE TABLE` statements using `PARTITION BY HASH`:

```
CREATE TABLE t1 (col1 INT, col2 CHAR(5))
  PARTITION BY HASH(col1);

CREATE TABLE t1 (col1 INT, col2 CHAR(5))
  PARTITION BY HASH( ORD(col2) );

CREATE TABLE t1 (col1 INT, col2 CHAR(5), col3 DATETIME)
  PARTITION BY HASH ( YEAR(col3) );
```

You may not use either `VALUES LESS THAN` or `VALUES IN` clauses with `PARTITION BY HASH`.

`PARTITION BY HASH` uses the remainder of *expr* divided by the number of partitions (that is, the modulus). For examples and additional information, see [Section 16.2.3, “HASH Partitioning”](#).

The `LINEAR` keyword entails a somewhat different algorithm. In this case, the number of the partition in which a row is stored is calculated as the result of one or more logical `AND` operations. For discussion and examples of linear hashing, see [Section 16.2.3.1, “LINEAR HASH Partitioning”](#).

- `KEY(column_list)`: This is similar to `HASH`, except that MySQL supplies the hashing function so as to guarantee an even data distribution. The *column_list* argument is simply a list of table columns. This example shows a simple table partitioned by key, with 4 partitions:

```
CREATE TABLE tk (col1 INT, col2 CHAR(5), col3 DATE)
  PARTITION BY KEY(col3)
  PARTITIONS 4;
```

For tables that are partitioned by key, you can employ linear partitioning by using the `LINEAR` keyword. This has the same effect as with tables that are partitioned by `HASH`. That is, the partition number is found using the `&` operator rather than the modulus (see [Section 16.2.3.1, “LINEAR HASH Partitioning”](#), and [Section 16.2.4, “KEY Partitioning”](#), for details). This example uses linear partitioning by key to distribute data between 5 partitions:

```
CREATE TABLE tk (col1 INT, col2 CHAR(5), col3 DATE)
  PARTITION BY LINEAR KEY(col3)
  PARTITIONS 5;
```

You may not use either `VALUES LESS THAN` or `VALUES IN` clauses with `PARTITION BY KEY`.

- **RANGE**: In this case, *expr* shows a range of values using a set of **VALUES LESS THAN** operators. When using range partitioning, you must define at least one partition using **VALUES LESS THAN**. You cannot use **VALUES IN** with range partitioning.

VALUES LESS THAN can be used with either a literal value or an expression that evaluates to a single value.

Suppose that you have a table that you wish to partition on a column containing year values, according to the following scheme:

Partition Number:	Years Range:
0	1990 and earlier
1	1991 – 1994
2	1995 – 1998
3	1999 – 2002
4	2003 – 2005
5	2006 and later

A table implementing such a partitioning scheme can be realized by the **CREATE TABLE** statement shown here:

```
CREATE TABLE t1 (
    year_col INT,
    some_data INT
)
PARTITION BY RANGE (year_col) (
    PARTITION p0 VALUES LESS THAN (1991),
    PARTITION p1 VALUES LESS THAN (1995),
    PARTITION p2 VALUES LESS THAN (1999),
    PARTITION p3 VALUES LESS THAN (2002),
    PARTITION p4 VALUES LESS THAN (2006),
    PARTITION p5 VALUES LESS THAN MAXVALUE
);
```

PARTITION ... VALUES LESS THAN ... statements work in a consecutive fashion. **VALUES LESS THAN MAXVALUE** works to specify “leftover” values that are greater than the maximum value otherwise specified.

Note that **VALUES LESS THAN** clauses work sequentially in a manner similar to that of the *case* portions of a **switch ... case** block (as found in many programming languages such as C, Java, and PHP). That is, the clauses must be arranged in such a way that the upper limit specified in each successive **VALUES LESS THAN** is greater than that of the previous one, with the one referencing **MAXVALUE** coming last of all in the list.

- **LIST(*expr*)**: This is useful when assigning partitions based on a table column with a restricted set of possible values, such as a state or country code. In such a case, all rows pertaining to a certain state or country can be assigned to a single partition, or a partition can be reserved for a certain set of states or countries. It is similar to **RANGE**, except that only **VALUES IN** may be used to specify allowable values for each partition.

VALUES IN is used with a list of values to be matched. For instance, you could create a partitioning scheme such as the following:

```
CREATE TABLE client_firms (
    id INT,
    name VARCHAR(35)
)
PARTITION BY LIST (id) (
    PARTITION r0 VALUES IN (1, 5, 9, 13, 17, 21),
```

```

PARTITION r1 VALUES IN (2, 6, 10, 14, 18, 22),
PARTITION r2 VALUES IN (3, 7, 11, 15, 19, 23),
PARTITION r3 VALUES IN (4, 8, 12, 16, 20, 24)
);

```

When using list partitioning, you must define at least one partition using `VALUES IN`. You cannot use `VALUES LESS THAN` with `PARTITION BY LIST`.

Note: Currently, the value list used with `VALUES IN` must consist of integer values only.

- The number of partitions may optionally be specified with a `PARTITIONS num` clause, where *num* is the number of partitions. If both this clause *and* any `PARTITION` clauses are used, *num* must be equal to the total number of any partitions that are declared using `PARTITION` clauses.

Note: Whether or not you use a `PARTITIONS` clause in creating a table that is partitioned by `RANGE` or `LIST`, you must still include at least one `PARTITION VALUES` clause in the table definition (see below).

- A partition may optionally be divided into a number of subpartitions. This can be indicated by using the optional `SUBPARTITION BY` clause. Subpartitioning may be done by `HASH` or `KEY`. Either of these may be `LINEAR`. These work in the same way as previously described for the equivalent partitioning types. (It is not possible to subpartition by `LIST` or `RANGE`.)

The number of subpartitions can be indicated using the `SUBPARTITIONS` keyword followed by an integer value.

- MySQL 5.1.12 introduces rigorous checking of the value used in a `PARTITIONS` or `SUBPARTITIONS` clause. Beginning with this version, this value must adhere to the following rules:
 - The value must be a positive, non-zero integer.
 - No leading zeroes are permitted.
 - The value must be an integer literal, and cannot not be an expression. For example, `PARTITIONS 0.2E+01` is not allowed, even though `0.2E+01` evaluates to 2. ([Bug#15890](http://bugs.mysql.com/15890) [<http://bugs.mysql.com/15890>])

Each partition may be individually defined using a `partition_definition` clause. The individual parts making up this clause are as follows:

- `PARTITION partition_name`: This specifies a logical name for the partition.
- A `VALUES` clause: For range partitioning, each partition must include a `VALUES LESS THAN` clause; for list partitioning, you must specify a `VALUES IN` clause for each partition. This is used to determine which rows are to be stored in this partition. See the discussions of partitioning types in [Chapter 16, Partitioning](#), for syntax examples.
- An optional `COMMENT` clause may be used to describe the partition. The comment must be set off in single quotes. Example:

```
COMMENT = 'Data for the years previous to 1999'
```

- `DATA DIRECTORY` and `INDEX DIRECTORY` may be used to indicate the directory where, respectively, the data and indexes for this partition are to be stored. Both the `data_dir` and the `index_dir` must be absolute system pathnames. Example:

```
CREATE TABLE th (id INT, name VARCHAR(30), adate DATE)
```

```

PARTITION BY LIST(YEAR(a.date))
(
  PARTITION p1999 VALUES IN (1995, 1999, 2003)
  DATA DIRECTORY = '/var/appdata/95/data'
  INDEX DIRECTORY = '/var/appdata/95/idx',
  PARTITION p2000 VALUES IN (1996, 2000, 2004)
  DATA DIRECTORY = '/var/appdata/96/data'
  INDEX DIRECTORY = '/var/appdata/96/idx',
  PARTITION p2001 VALUES IN (1997, 2001, 2005)
  DATA DIRECTORY = '/var/appdata/97/data'
  INDEX DIRECTORY = '/var/appdata/97/idx',
  PARTITION p2000 VALUES IN (1998, 2002, 2006)
  DATA DIRECTORY = '/var/appdata/98/data'
  INDEX DIRECTORY = '/var/appdata/98/idx'
);

```

`DATA DIRECTORY` and `INDEX DIRECTORY` behave in the same way as in the `CREATE TABLE` statement's `table_option` clause as used for `MyISAM` tables.

One data directory and one index directory may be specified per partition. If left unspecified, the data and indexes are stored by default in the MySQL data directory.

- `MAX_ROWS` and `MIN_ROWS` may be used to specify, respectively, the maximum and minimum number of rows to be stored in the partition. The values for `max_number_of_rows` and `min_number_of_rows` must be positive integers. As with the table-level options with the same names, these act only as “suggestions” to the server and are not hard limits.
- The optional `TABLESPACE` clause may be used to designate a tablespace for the partition. Used for MySQL Cluster only.
- The optional `[STORAGE] ENGINE` clause causes the tables in this partition to use the storage engine specified, which may be any engine supported by this MySQL server. Both the `STORAGE` keyword and the equals sign (=) are optional. If no partition-specific storage engine is set using this option, the engine applying to the table as a whole is used for this partition.

Note: The partitioning handler accepts a `[STORAGE] ENGINE` option for both `PARTITION` and `SUBPARTITION`. Currently, the only way in which this can be used is to set all partitions or all subpartitions to the same storage engine, and an attempt to set different storage engines for partitions or subpartitions in the same table will give rise to the error `ERROR 1469 (HY000): The mix of handlers in the partitions is not allowed in this version of MySQL`. We expect to lift this restriction on partitioning in a future MySQL 5.1 release.

- The `NODEGROUP` option can be used to make this partition act as part of the node group identified by `node_group_id`. This option is applicable only to MySQL Cluster.
- The partition definition may optionally contain one or more `subpartition_definition` clauses. Each of these consists at a minimum of the `SUBPARTITION name`, where `name` is an identifier for the subpartition. Except for the replacement of the `PARTITION` keyword with `SUBPARTITION`, the syntax for a subpartition definition is identical to that for a partition definition.

Subpartitioning must be done by `HASH` or `KEY`, and can be done only on `RANGE` or `LIST` partitions. See [Section 16.2.5, “Subpartitioning”](#).

Partitions can be modified, merged, added to tables, and dropped from tables. For basic information about the MySQL statements to accomplish these tasks, see [Section 13.1.2, “ALTER TABLE Syntax”](#). For more detailed descriptions and examples, see [Section 16.3, “Partition Management”](#).

You can create one table from another by adding a `SELECT` statement at the end of the `CREATE TABLE` statement:

```
CREATE TABLE new_tbl SELECT * FROM orig_tbl;
```

MySQL creates new columns for all elements in the `SELECT`. For example:

```
mysql> CREATE TABLE test (a INT NOT NULL AUTO_INCREMENT,
-> PRIMARY KEY (a), KEY(b))
-> ENGINE=MyISAM SELECT b,c FROM test2;
```

This creates a `MyISAM` table with three columns, `a`, `b`, and `c`. Notice that the columns from the `SELECT` statement are appended to the right side of the table, not overlapped onto it. Take the following example:

```
mysql> SELECT * FROM foo;
+----+
| n |
+----+
| 1 |
+----+

mysql> CREATE TABLE bar (m INT) SELECT n FROM foo;
Query OK, 1 row affected (0.02 sec)
Records: 1 Duplicates: 0 Warnings: 0

mysql> SELECT * FROM bar;
+-----+-----+
| m | n |
+-----+-----+
| NULL | 1 |
+-----+-----+
1 row in set (0.00 sec)
```

For each row in table `foo`, a row is inserted in `bar` with the values from `foo` and default values for the new columns.

In a table resulting from `CREATE TABLE ... SELECT`, columns named only in the `CREATE TABLE` part come first. Columns named in both parts or only in the `SELECT` part come after that. The data type of `SELECT` columns can be overridden by also specifying the column in the `CREATE TABLE` part.

If any errors occur while copying the data to the table, it is automatically dropped and not created.

`CREATE TABLE ... SELECT` does not automatically create any indexes for you. This is done intentionally to make the statement as flexible as possible. If you want to have indexes in the created table, you should specify these before the `SELECT` statement:

```
mysql> CREATE TABLE bar (UNIQUE (n)) SELECT n FROM foo;
```

Some conversion of data types might occur. For example, the `AUTO_INCREMENT` attribute is not preserved, and `VARCHAR` columns can become `CHAR` columns.

When creating a table with `CREATE ... SELECT`, make sure to alias any function calls or expressions in the query. If you do not, the `CREATE` statement might fail or result in undesirable column names.

```
CREATE TABLE artists_and_works
SELECT artist.name, COUNT(work.artist_id) AS number_of_works
FROM artist LEFT JOIN work ON artist.id = work.artist_id
GROUP BY artist.id;
```

You can also explicitly specify the data type for a generated column:

```
CREATE TABLE foo (a TINYINT NOT NULL) SELECT b+1 AS a FROM bar;
```

Use `LIKE` to create an empty table based on the definition of another table, including any column attributes and indexes defined in the original table:

```
CREATE TABLE new_tbl LIKE orig_tbl;
```

`CREATE TABLE ... LIKE` does not preserve any `DATA DIRECTORY` or `INDEX DIRECTORY` table options that were specified for the original table, or any foreign key definitions.

You can precede the `SELECT` by `IGNORE` or `REPLACE` to indicate how to handle rows that duplicate unique key values. With `IGNORE`, new rows that duplicate an existing row on a unique key value are discarded. With `REPLACE`, new rows replace rows that have the same unique key value. If neither `IGNORE` nor `REPLACE` is specified, duplicate unique key values result in an error.

To ensure that the binary log can be used to re-create the original tables, MySQL does not allow concurrent inserts during `CREATE TABLE ... SELECT`.

13.1.8. CREATE LOGFILE GROUP Syntax

```
CREATE LOGFILE GROUP logfile_group
  ADD UNDOFILE 'undo_file'
  INITIAL_SIZE [=] initial_size
  [UNDO_BUFFER_SIZE [=] undo_buffer_size]
  ENGINE [=] engine_name
```

This statement creates a new logfile group named *logfile_group* having a single `UNDO` file named '*undo_file*'. A `CREATE LOGFILE GROUP` statement has one and only one `ADD UNDOFILE` clause.

Beginning with MySQL 5.1.8, you can have only one logfile group per Cluster at any given time. (See [Bug#16386](http://bugs.mysql.com/16386) [http://bugs.mysql.com/16386])

The `INITIAL_SIZE` parameter sets the `UNDO` file's initial size. The optional `UNDO_BUFFER_SIZE` parameter sets the size used by the `UNDO` buffer for the logfile group; The default value for `UNDO_BUFFER_SIZE` is `8M` (eight megabytes); this value cannot exceed the amount of system memory available. Both *initial_size* and *undo_buffer_size* are specified in bytes. You may optionally follow either or both of these with a one-letter abbreviation for an order of magnitude, similar to those used in *my.cnf*. Generally, this is one of the letters `M` (for megabytes) or `G` (for gigabytes).

The `ENGINE` parameter determines the storage engine to be used by this logfile group, with *engine* being the name of the storage engine. In MySQL 5.1, *engine* must be one of the values `NDB` or `NDB-CLUSTER`.

When used with `ENGINE = NDB`, a logfile group and associated `UNDO` logfile are created on each Cluster data node. You can verify that the `UNDO` files were created and obtain information about them by querying the `INFORMATION_SCHEMA.FILES` table. For example:

```
mysql> SELECT LOGFILE_GROUP_NAME, LOGFILE_GROUP_NUMBER, EXTRA
-> FROM INFORMATION_SCHEMA.FILES
-> WHERE FILE_NAME = 'undo_10.dat';
```

LOGFILE_GROUP_NAME	LOGFILE_GROUP_NUMBER	EXTRA
lg_3	11	CLUSTER_NODE=3
lg_3	11	CLUSTER_NODE=4

2 rows in set (0.06 sec)

(See [Section 22.21](#), “The `INFORMATION_SCHEMA.FILES` Table”.)

`CREATE LOGFILE GROUP` was added in MySQL 5.1.6. In MySQL 5.1, it is useful only with Disk Data storage for MySQL Cluster. See [Section 15.11](#), “MySQL Cluster Disk Data Storage”.

13.1.9. CREATE TABLESPACE Syntax

```
CREATE TABLESPACE tablespace
  ADD DATAFILE 'file'
  USE LOGFILE GROUP logfile_group
  [EXTENT_SIZE [=] extent_size]
  INITIAL_SIZE [=] initial_size
  ENGINE [=] engine
```

This statement is used to create a tablespace, which can contain one or more datafiles, providing storage space for tables. One datafile is created and added to the tablespace using this statement. Additional datafiles may be added to the tablespace by using the `ALTER TABLESPACE` statement (see [Section 13.1.4, “ALTER TABLESPACE Syntax”](#)).

A logfile group of one or more `UNDO` log files must be assigned to the tablespace to be created with the `USE LOGFILE GROUP` clause. `logfile_group` must be an existing logfile group created with `CREATE LOGFILE GROUP` (see [Section 13.1.8, “CREATE LOGFILE GROUP Syntax”](#)). Multiple tablespaces may use the same logfile group for `UNDO` logging.

The `EXTENT_SIZE` sets the size, in bytes, of the extents used by any files belonging to the tablespace. The default value is 4 bytes.

An *extent* is a unit of disk space allocation. One extent is filled with as much data as that extent can contain before another extent is used. You can see how many extents for a given file remain free by querying the `INFORMATION_SCHEMA.FILES` table, and so derive an estimate for how much space remains free in the file. For further discussion and examples, see [Section 22.21, “The INFORMATION_SCHEMA FILES Table”](#).

The `INITIAL_SIZE` parameter sets the datafile's total size in bytes. Once the file has been created, its size cannot be changed; however, you can add more datafiles to the tablespace using `ALTER TABLESPACE ... ADD DATAFILE`. See [Section 13.1.4, “ALTER TABLESPACE Syntax”](#).

When setting `EXTENT_SIZE` or `INITIAL_SIZE` (either or both), you may optionally follow the number with a one-letter abbreviation for an order of magnitude, similar to those used in `my.cnf`. Generally, this is one of the letters `M` (for megabytes) or `G` (for gigabytes).

The `ENGINE` parameter determines the storage engine which uses this tablespace, with *engine* being the name of the storage engine. In MySQL 5.1, *engine* must be one of the values `NDB` or `NDB-CLUSTER`.

When `CREATE TABLESPACE` is used with `ENGINE = NDB`, a tablespace and associated datafile are created on each Cluster data node. You can verify that the datafiles were created and obtain information about them by querying the `INFORMATION_SCHEMA.FILES` table. For example:

```
mysql> SELECT LOGFILE_GROUP_NAME, FILE_NAME, EXTRA
  -> FROM INFORMATION_SCHEMA.FILES
  -> WHERE TABLESPACE_NAME = 'newts' AND FILE_TYPE = 'DATAFILE';
+-----+-----+-----+
| LOGFILE_GROUP_NAME | FILE_NAME | EXTRA |
+-----+-----+-----+
| lg_3               | newdata.dat | CLUSTER_NODE=3 |
| lg_3               | newdata.dat | CLUSTER_NODE=4 |
+-----+-----+-----+
2 rows in set (0.01 sec)
```

(See [Section 22.21, “The INFORMATION_SCHEMA FILES Table”](#)).

`CREATE TABLESPACE` was added in MySQL 5.1.6. In MySQL 5.1, it is useful only with Disk Data storage for MySQL Cluster. See [Section 15.11, “MySQL Cluster Disk Data Storage”](#).

13.1.10. DROP DATABASE Syntax

```
DROP {DATABASE | SCHEMA} [IF EXISTS] db_name
```

`DROP DATABASE` drops all tables in the database and deletes the database. Be *very* careful with this statement! To use `DROP DATABASE`, you need the `DROP` privilege on the database. `DROP SCHEMA` is a synonym for `DROP DATABASE`.

Important: When a database is dropped, user privileges on the database are *not* automatically dropped. See [Section 13.5.1.3, “GRANT Syntax”](#).

`IF EXISTS` is used to prevent an error from occurring if the database does not exist.

If you use `DROP DATABASE` on a symbolically linked database, both the link and the original database are deleted.

`DROP DATABASE` returns the number of tables that were removed. This corresponds to the number of `.frm` files removed.

The `DROP DATABASE` statement removes from the given database directory those files and directories that MySQL itself may create during normal operation:

- All files with these extensions:

<code>.BAK</code>	<code>.DAT</code>	<code>.HSH</code>	<code>.MRG</code>
<code>.MYD</code>	<code>.MYI</code>	<code>.TRG</code>	<code>.TRN</code>
<code>.db</code>	<code>.frm</code>	<code>.ibd</code>	<code>.ndb</code>
<code>.par</code>			

- The `db.opt` file, if it exists.

If other files or directories remain in the database directory after MySQL removes those just listed, the database directory cannot be removed. In this case, you must remove any remaining files or directories manually and issue the `DROP DATABASE` statement again.

You can also drop databases with `mysqladmin`. See [Section 8.8, “mysqladmin — Client for Administering a MySQL Server”](#).

13.1.11. DROP INDEX Syntax

```
DROP INDEX index_name ON tbl_name
```

`DROP INDEX` drops the index named `index_name` from the table `tbl_name`. This statement is mapped to an `ALTER TABLE` statement to drop the index. See [Section 13.1.2, “ALTER TABLE Syntax”](#).

13.1.12. DROP TABLE Syntax

```
DROP [TEMPORARY] TABLE [IF EXISTS]
  tbl_name [, tbl_name] ...
  [RESTRICT | CASCADE]
```

`DROP TABLE` removes one or more tables. You must have the `DROP` privilege for each table. All table data and the table definition are *removed*, so *be careful* with this statement! If any of the tables named in the argument list do not exist, MySQL returns an error indicating by name which non-existing tables it

was unable to drop, but it also drops all of the tables in the list that do exist.

Important: When a table is dropped, user privileges on the table are *not* automatically dropped. See [Section 13.5.1.3, “GRANT Syntax”](#).

Note that for a partitioned table, `DROP TABLE` permanently removes the table definition, all of its partitions, and all of the data which was stored in those partitions. It also removes the partitioning definition (`.par`) file associated with the dropped table.

Use `IF EXISTS` to prevent an error from occurring for tables that do not exist. A `NOTE` is generated for each non-existent table when using `IF EXISTS`. See [Section 13.5.4.30, “SHOW WARNINGS Syntax”](#).

`RESTRICT` and `CASCADE` are allowed to make porting easier. In MySQL 5.1, they do nothing.

Note: `DROP TABLE` automatically commits the current active transaction, unless you use the `TEMPORARY` keyword.

The `TEMPORARY` keyword has the following effects:

- The statement drops only `TEMPORARY` tables.
- The statement does not end an ongoing transaction.
- No access rights are checked. (A `TEMPORARY` table is visible only to the client that created it, so no check is necessary.)

Using `TEMPORARY` is a good way to ensure that you do not accidentally drop a non-`TEMPORARY` table.

13.1.13. DROP LOGFILE GROUP Syntax

```
DROP LOGFILE GROUP logfile_group
ENGINE [=] engine
```

This statement drops the logfile group named *logfile_group*. The logfile group must already exist or an error results. (For information on creating logfile groups, see [Section 13.1.8, “CREATE LOGFILE GROUP Syntax”](#).)

Important: Before dropping a logfile group, you must drop all tablespaces that use that logfile group for `UNDO` logging.

The required `ENGINE` clause provides the name of the storage engine used by the logfile group to be dropped. In MySQL 5.1, the only permitted values for *engine* are `NDB` and `NDBCLUSTER`.

`DROP LOGFILE GROUP` was added in MySQL 5.1.6. In MySQL 5.1, it is useful only with Disk Data storage for MySQL Cluster. See [Section 15.11, “MySQL Cluster Disk Data Storage”](#).

13.1.14. DROP TABLESPACE Syntax

```
DROP TABLESPACE tablespace
ENGINE [=] engine
```

This statement drops a tablespace that was previously created using `CREATE TABLESPACE` (see [Section 13.1.9, “CREATE TABLESPACE Syntax”](#)).

Important: The tablespace to be dropped must not contain any datafiles; in other words, before you can drop a tablespace, you must first drop each of its datafiles using `ALTER TABLESPACE ... DROP`

`DATAFILE` (see [Section 13.1.4](#), “`ALTER TABLESPACE Syntax`”).

The `ENGINE` clause (required) specifies the storage engine used by the tablespace. In MySQL 5.1, the only accepted values for *engine* are `NDB` and `NDBCLUSTER`.

`DROP TABLESPACE` was added in MySQL 5.1.6. In MySQL 5.1, it is useful only with Disk Data storage for MySQL Cluster. See [Section 15.11](#), “`MySQL Cluster Disk Data Storage`”.

13.1.15. `RENAME DATABASE Syntax`

```
RENAME {DATABASE | SCHEMA} db_name TO new_db_name ;
```

This statement renames a database. It requires the `ALTER` and `DROP` privileges for the database, and the `CREATE` privilege for the new database. `RENAME SCHEMA` is a synonym for `RENAME DATABASE`.

When the server receives this statement, it creates a new database. Then it moves tables and other database objects such as triggers to the new database. It also updates the `Db` column in the system tables for objects such as stored routines and events. Finally, the server drops the old database.

Note that currently there are these limitations:

- `RENAME DATABASE` does not change any account privileges listed in the system tables. This needs to be changed manually.
- `RENAME DATABASE` does not migrate any stored routines or events to the new schema name. This means that:
 - For stored routines, it does not change any values in the `ROUTINE_SCHEMA` column of the `INFORMATION_SCHEMA.ROUTINES` table, or in the `db` column of the `mysql.proc` table.
 - For events, it does not change any values in the `EVENT_SCHEMA` column of the `INFORMATION_SCHEMA.EVENTS` table, or in the `db` column of the `mysql.event` table.

This statement was added in MySQL 5.1.7.

13.1.16. `RENAME TABLE Syntax`

```
RENAME TABLE tbl_name TO new_tbl_name
[, tbl_name2 TO new_tbl_name2] ...
```

This statement renames one or more tables.

The rename operation is done atomically, which means that no other thread can access any of the tables while the rename is running. For example, if you have an existing table `old_table`, you can create another table `new_table` that has the same structure but is empty, and then replace the existing table with the empty one as follows (assuming that `backup_table` does not already exist):

```
CREATE TABLE new_table (...);
RENAME TABLE old_table TO backup_table, new_table TO old_table;
```

If the statement renames more than one table, renaming operations are done from left to right. If you want to swap two table names, you can do so like this (assuming that `tmp_table` does not already exist):

```
RENAME TABLE old_table TO tmp_table,
              new_table TO old_table,
              tmp_table TO new_table;
```

As long as two databases are on the same filesystem, you can use `RENAME TABLE` to move a table from one database to another:

```
RENAME TABLE current_db.tbl_name TO other_db.tbl_name;
```

`RENAME TABLE` also works for views, as long as you do not try to rename a view into a different database.

When you execute `RENAME`, you cannot have any locked tables or active transactions. You must also have the `ALTER` and `DROP` privileges on the original table, and the `CREATE` and `INSERT` privileges on the new table.

If MySQL encounters any errors in a multiple-table rename, it does a reverse rename for all renamed tables to return everything to its original state.

13.2. Data Manipulation Statements

13.2.1. DELETE Syntax

Single-table syntax:

```
DELETE [LOW_PRIORITY] [QUICK] [IGNORE] FROM tbl_name
  [WHERE where_condition]
  [ORDER BY ...]
  [LIMIT row_count]
```

Multiple-table syntax:

```
DELETE [LOW_PRIORITY] [QUICK] [IGNORE]
  tbl_name[*] [, tbl_name[*]] ...
  FROM table_references
  [WHERE where_condition]
```

Or:

```
DELETE [LOW_PRIORITY] [QUICK] [IGNORE]
  FROM tbl_name[*] [, tbl_name[*]] ...
  USING table_references
  [WHERE where_condition]
```

For the single-table syntax, the `DELETE` statement deletes rows from `tbl_name` and returns the number of rows deleted. The `WHERE` clause, if given, specifies the conditions that identify which rows to delete. With no `WHERE` clause, all rows are deleted. If the `ORDER BY` clause is specified, the rows are deleted in the order that is specified. The `LIMIT` clause places a limit on the number of rows that can be deleted.

For the multiple-table syntax, `DELETE` deletes from each `tbl_name` the rows that satisfy the conditions. In this case, `ORDER BY` and `LIMIT` cannot be used.

`where_condition` is an expression that evaluates to true for each row to be deleted. It is specified as described in [Section 13.2.7, “SELECT Syntax”](#).

As stated, a `DELETE` statement with no `WHERE` clause deletes all rows. A faster way to do this, when you do not want to know the number of deleted rows, is to use `TRUNCATE TABLE`. See [Section 13.2.9, “TRUNCATE Syntax”](#).

If you delete the row containing the maximum value for an `AUTO_INCREMENT` column, the value is

not reused for a `MyISAM` or `InnoDB` table. If you delete all rows in the table with `DELETE FROM tbl_name` (without a `WHERE` clause) in `AUTOCOMMIT` mode, the sequence starts over for all storage engines except `InnoDB` and `MyISAM`. There are some exceptions to this behavior for `InnoDB` tables, as discussed in [Section 14.5.6.3, “How `AUTO_INCREMENT` Columns Work in `InnoDB`”](#).

For `MyISAM` tables, you can specify an `AUTO_INCREMENT` secondary column in a multiple-column key. In this case, reuse of values deleted from the top of the sequence occurs even for `MyISAM` tables. See [Section 3.6.9, “Using `AUTO_INCREMENT`”](#).

The `DELETE` statement supports the following modifiers:

- If you specify `LOW_PRIORITY`, the server delays execution of the `DELETE` until no other clients are reading from the table.
- For `MyISAM` tables, if you use the `QUICK` keyword, the storage engine does not merge index leaves during delete, which may speed up some kinds of delete operations.
- The `IGNORE` keyword causes MySQL to ignore all errors during the process of deleting rows. (Errors encountered during the parsing stage are processed in the usual manner.) Errors that are ignored due to the use of `OPTION` are returned as warnings.

The speed of delete operations may also be affected by factors discussed in [Section 7.2.18, “Speed of `DELETE` Statements”](#).

In `MyISAM` tables, deleted rows are maintained in a linked list and subsequent `INSERT` operations reuse old row positions. To reclaim unused space and reduce file sizes, use the `OPTIMIZE TABLE` statement or the `myisamchk` utility to reorganize tables. `OPTIMIZE TABLE` is easier, but `myisamchk` is faster. See [Section 13.5.2.5, “`OPTIMIZE TABLE` Syntax”](#), and [Section 8.3, “`myisamchk` — `MyISAM` Table-Maintenance Utility”](#).

The `QUICK` modifier affects whether index leaves are merged for delete operations. `DELETE QUICK` is most useful for applications where index values for deleted rows are replaced by similar index values from rows inserted later. In this case, the holes left by deleted values are reused.

`DELETE QUICK` is not useful when deleted values lead to under-filled index blocks spanning a range of index values for which new inserts occur again. In this case, use of `QUICK` can lead to wasted space in the index that remains unreclaimed. Here is an example of such a scenario:

1. Create a table that contains an indexed `AUTO_INCREMENT` column.
2. Insert many rows into the table. Each insert results in an index value that is added to the high end of the index.
3. Delete a block of rows at the low end of the column range using `DELETE QUICK`.

In this scenario, the index blocks associated with the deleted index values become under-filled but are not merged with other index blocks due to the use of `QUICK`. They remain under-filled when new inserts occur, because new rows do not have index values in the deleted range. Furthermore, they remain under-filled even if you later use `DELETE` without `QUICK`, unless some of the deleted index values happen to lie in index blocks within or adjacent to the under-filled blocks. To reclaim unused index space under these circumstances, use `OPTIMIZE TABLE`.

If you are going to delete many rows from a table, it might be faster to use `DELETE QUICK` followed by `OPTIMIZE TABLE`. This rebuilds the index rather than performing many index block merge operations.

The MySQL-specific `LIMIT row_count` option to `DELETE` tells the server the maximum number of rows to be deleted before control is returned to the client. This can be used to ensure that a given `DELETE` statement does not take too much time. You can simply repeat the `DELETE` statement until the number of affected rows is less than the `LIMIT` value.

If the `DELETE` statement includes an `ORDER BY` clause, the rows are deleted in the order specified by the clause. This is really useful only in conjunction with `LIMIT`. For example, the following statement finds rows matching the `WHERE` clause, sorts them by `timestamp_column`, and deletes the first (oldest) one:

```
DELETE FROM somelog WHERE user = 'jcole'
ORDER BY timestamp_column LIMIT 1;
```

You can specify multiple tables in a `DELETE` statement to delete rows from one or more tables depending on the particular condition in the `WHERE` clause. However, you cannot use `ORDER BY` or `LIMIT` in a multiple-table `DELETE`. The *table_references* clause lists the tables involved in the join. Its syntax is described in [Section 13.2.7.1, “JOIN Syntax”](#).

For the first multiple-table syntax, only matching rows from the tables listed before the `FROM` clause are deleted. For the second multiple-table syntax, only matching rows from the tables listed in the `FROM` clause (before the `USING` clause) are deleted. The effect is that you can delete rows from many tables at the same time and have additional tables that are used only for searching:

```
DELETE t1, t2 FROM t1, t2, t3 WHERE t1.id=t2.id AND t2.id=t3.id;
```

Or:

```
DELETE FROM t1, t2 USING t1, t2, t3 WHERE t1.id=t2.id AND t2.id=t3.id;
```

These statements use all three tables when searching for rows to delete, but delete matching rows only from tables `t1` and `t2`.

The preceding examples show inner joins that use the comma operator, but multiple-table `DELETE` statements can use any type of join allowed in `SELECT` statements, such as `LEFT JOIN`.

The syntax allows `. *` after the table names for compatibility with `Access`.

If you use a multiple-table `DELETE` statement involving `InnoDB` tables for which there are foreign key constraints, the MySQL optimizer might process tables in an order that differs from that of their parent/child relationship. In this case, the statement fails and rolls back. Instead, you should delete from a single table and rely on the `ON DELETE` capabilities that `InnoDB` provides to cause the other tables to be modified accordingly.

Note: If you provide an alias for a table, you must use the alias when referring to the table:

```
DELETE t1 FROM test AS t1, test2 WHERE ...
```

Cross-database deletes are supported for multiple-table deletes, but in this case, you must refer to the tables without using aliases. For example:

```
DELETE test1.tmp1, test2.tmp2 FROM test1.tmp1, test2.tmp2 WHERE ...
```

Currently, you cannot delete from a table and select from the same table in a subquery.

13.2.2. DO Syntax

```
DO expr [, expr] ...
```

`DO` executes the expressions but does not return any results. In most respects, `DO` is shorthand for `SELECT expr, ...`, but has the advantage that it is slightly faster when you do not care about the result.

`DO` is useful primarily with functions that have side effects, such as `RELEASE_LOCK()`.

13.2.3. HANDLER Syntax

```
HANDLER tbl_name OPEN [ AS alias ]
HANDLER tbl_name READ index_name { = | >= | <= | < } (value1,value2,...)
  [ WHERE where_condition ] [LIMIT ... ]
HANDLER tbl_name READ index_name { FIRST | NEXT | PREV | LAST }
  [ WHERE where_condition ] [LIMIT ... ]
HANDLER tbl_name READ { FIRST | NEXT }
  [ WHERE where_condition ] [LIMIT ... ]
HANDLER tbl_name CLOSE
```

The `HANDLER` statement provides direct access to table storage engine interfaces. It is available for `MyISAM` and `InnoDB` tables.

The `HANDLER ... OPEN` statement opens a table, making it accessible via subsequent `HANDLER ... READ` statements. This table object is not shared by other threads and is not closed until the thread calls `HANDLER ... CLOSE` or the thread terminates. If you open the table using an alias, further references to the open table with other `HANDLER` statements must use the alias rather than the table name.

The first `HANDLER ... READ` syntax fetches a row where the index specified satisfies the given values and the `WHERE` condition is met. If you have a multiple-column index, specify the index column values as a comma-separated list. Either specify values for all the columns in the index, or specify values for a leftmost prefix of the index columns. Suppose that an index `my_idx` includes three columns named `col_a`, `col_b`, and `col_c`, in that order. The `HANDLER` statement can specify values for all three columns in the index, or for the columns in a leftmost prefix. For example:

```
HANDLER ... READ my_idx = (col_a_val,col_b_val,col_c_val) ...
HANDLER ... READ my_idx = (col_a_val,col_b_val) ...
HANDLER ... READ my_idx = (col_a_val) ...
```

To employ the `HANDLER` interface to refer to a table's `PRIMARY KEY`, use the quoted identifier ``PRIMARY``:

```
HANDLER tbl_name READ `PRIMARY` ...
```

The second `HANDLER ... READ` syntax fetches a row from the table in index order that matches the `WHERE` condition.

The third `HANDLER ... READ` syntax fetches a row from the table in natural row order that matches the `WHERE` condition. It is faster than `HANDLER tbl_name READ index_name` when a full table scan is desired. Natural row order is the order in which rows are stored in a `MyISAM` table data file. This statement works for `InnoDB` tables as well, but there is no such concept because there is no separate data file.

Without a `LIMIT` clause, all forms of `HANDLER ... READ` fetch a single row if one is available. To return a specific number of rows, include a `LIMIT` clause. It has the same syntax as for the `SELECT` statement. See [Section 13.2.7, “SELECT Syntax”](#).

`HANDLER ... CLOSE` closes a table that was opened with `HANDLER ... OPEN`.

`HANDLER` is a somewhat low-level statement. For example, it does not provide consistency. That is, `HANDLER ... OPEN` does *not* take a snapshot of the table, and does *not* lock the table. This means

that after a `HANDLER ... OPEN` statement is issued, table data can be modified (by the current thread or other threads) and these modifications might be only partially visible to `HANDLER ... NEXT` or `HANDLER ... PREV` scans.

There are several reasons to use the `HANDLER` interface instead of normal `SELECT` statements:

- `HANDLER` is faster than `SELECT`:
 - A designated storage engine handler object is allocated for the `HANDLER ... OPEN`. The object is reused for subsequent `HANDLER` statements for that table; it need not be reinitialized for each one.
 - There is less parsing involved.
 - There is no optimizer or query-checking overhead.
 - The table does not have to be locked between two handler requests.
 - The handler interface does not have to provide a consistent look of the data (for example, dirty reads are allowed), so the storage engine can use optimizations that `SELECT` does not normally allow.
- For applications that use a low-level `ISAM`-like interface, `HANDLER` makes it much easier to port them to MySQL.
- `HANDLER` enables you to traverse a database in a manner that is difficult (or even impossible) to accomplish with `SELECT`. The `HANDLER` interface is a more natural way to look at data when working with applications that provide an interactive user interface to the database.

13.2.4. INSERT Syntax

```
INSERT [LOW_PRIORITY | DELAYED | HIGH_PRIORITY] [IGNORE]
  [INTO] tbl_name [(col_name,...)]
  VALUES ({expr | DEFAULT},...),(...),...
  [ ON DUPLICATE KEY UPDATE col_name=expr, ... ]
```

Or:

```
INSERT [LOW_PRIORITY | DELAYED | HIGH_PRIORITY] [IGNORE]
  [INTO] tbl_name
  SET col_name={expr | DEFAULT}, ...
  [ ON DUPLICATE KEY UPDATE col_name=expr, ... ]
```

Or:

```
INSERT [LOW_PRIORITY | HIGH_PRIORITY] [IGNORE]
  [INTO] tbl_name [(col_name,...)]
  SELECT ...
  [ ON DUPLICATE KEY UPDATE col_name=expr, ... ]
```

`INSERT` inserts new rows into an existing table. The `INSERT ... VALUES` and `INSERT ... SET` forms of the statement insert rows based on explicitly specified values. The `INSERT ... SELECT` form inserts rows selected from another table or tables. `INSERT ... SELECT` is discussed further in [Section 13.2.4.1, “INSERT ... SELECT Syntax”](#).

You can use `REPLACE` instead of `INSERT` to overwrite old rows. `REPLACE` is the counterpart to `INSERT IGNORE` in the treatment of new rows that contain unique key values that duplicate old rows: The new rows are used to replace the old rows rather than being discarded. See [Section 13.2.6, “REPLACE Syntax”](#).

tbl_name is the table into which rows should be inserted. The columns for which the statement provides values can be specified as follows:

- You can provide a comma-separated list of column names following the table name. In this case, a value for each named column must be provided by the `VALUES` list or the `SELECT` statement.
- If you do not specify a list of column names for `INSERT ... VALUES` or `INSERT ... SELECT`, values for every column in the table must be provided by the `VALUES` list or the `SELECT` statement. If you do not know the order of the columns in the table, use `DESCRIBE tbl_name` to find out.
- The `SET` clause indicates the column names explicitly.

Column values can be given in several ways:

- If you are not running in strict SQL mode, any column not explicitly given a value is set to its default (explicit or implicit) value. For example, if you specify a column list that does not name all the columns in the table, unnamed columns are set to their default values. Default value assignment is described in [Section 11.1.4, “Data Type Default Values”](#). See also [Section 1.9.6.2, “Constraints on Invalid Data”](#).

If you want an `INSERT` statement to generate an error unless you explicitly specify values for all columns that do not have a default value, you should use strict mode. See [Section 5.2.6, “SQL Modes”](#).

- Use the keyword `DEFAULT` to set a column explicitly to its default value. This makes it easier to write `INSERT` statements that assign values to all but a few columns, because it enables you to avoid writing an incomplete `VALUES` list that does not include a value for each column in the table. Otherwise, you would have to write out the list of column names corresponding to each value in the `VALUES` list.

You can also use `DEFAULT(col_name)` as a more general form that can be used in expressions to produce a given column's default value.

- If both the column list and the `VALUES` list are empty, `INSERT` creates a row with each column set to its default value:

```
INSERT INTO tbl_name () VALUES();
```

In strict mode, an error occurs if any column doesn't have a default value. Otherwise, MySQL uses the implicit default value for any column that does not have an explicitly defined default.

- You can specify an expression *expr* to provide a column value. This might involve type conversion if the type of the expression does not match the type of the column, and conversion of a given value can result in different inserted values depending on the data type. For example, inserting the string `'1999.0e-2'` into an `INT`, `FLOAT`, `DECIMAL(10,6)`, or `YEAR` column results in the values `1999`, `19.9921`, `19.992100`, and `1999` being inserted, respectively. The reason the value stored in the `INT` and `YEAR` columns is `1999` is that the string-to-integer conversion looks only at as much of the initial part of the string as may be considered a valid integer or year. For the floating-point and fixed-point columns, the string-to-floating-point conversion considers the entire string a valid floating-point value.

An expression *expr* can refer to any column that was set earlier in a value list. For example, you can do this because the value for `col2` refers to `col1`, which has previously been assigned:

```
INSERT INTO tbl_name (col1,col2) VALUES(15,col1*2);
```

But the following is not legal, because the value for `col1` refers to `col2`, which is assigned after `col1`:

```
INSERT INTO tbl_name (col1,col2) VALUES(col2*2,15);
```

One exception involves columns that contain `AUTO_INCREMENT` values. Because the `AUTO_INCREMENT` value is generated after other value assignments, any reference to an `AUTO_INCREMENT` column in the assignment returns a 0.

`INSERT` statements that use `VALUES` syntax can insert multiple rows. To do this, include multiple lists of column values, each enclosed within parentheses and separated by commas. Example:

```
INSERT INTO tbl_name (a,b,c) VALUES(1,2,3),(4,5,6),(7,8,9);
```

The values list for each row must be enclosed within parentheses. The following statement is illegal because the number of values in the list does not match the number of column names:

```
INSERT INTO tbl_name (a,b,c) VALUES(1,2,3,4,5,6,7,8,9);
```

The rows-affected value for an `INSERT` can be obtained using the `mysql_affected_rows()` C API function. See [Section 24.2.3.1](#), “`mysql_affected_rows()`”.

If you use an `INSERT ... VALUES` statement with multiple value lists or `INSERT ... SELECT`, the statement returns an information string in this format:

```
Records: 100 Duplicates: 0 Warnings: 0
```

`Records` indicates the number of rows processed by the statement. (This is not necessarily the number of rows actually inserted because `Duplicates` can be non-zero.) `Duplicates` indicates the number of rows that could not be inserted because they would duplicate some existing unique index value. `Warnings` indicates the number of attempts to insert column values that were problematic in some way. Warnings can occur under any of the following conditions:

- Inserting `NULL` into a column that has been declared `NOT NULL`. For multiple-row `INSERT` statements or `INSERT INTO ... SELECT` statements, the column is set to the implicit default value for the column data type. This is 0 for numeric types, the empty string (' ') for string types, and the “zero” value for date and time types. `INSERT INTO ... SELECT` statements are handled the same way as multiple-row inserts because the server does not examine the result set from the `SELECT` to see whether it returns a single row. (For a single-row `INSERT`, no warning occurs when `NULL` is inserted into a `NOT NULL` column. Instead, the statement fails with an error.)
- Setting a numeric column to a value that lies outside the column's range. The value is clipped to the closest endpoint of the range.
- Assigning a value such as `'10.34 a'` to a numeric column. The trailing non-numeric text is stripped off and the remaining numeric part is inserted. If the string value has no leading numeric part, the column is set to 0.
- Inserting a string into a string column (`CHAR`, `VARCHAR`, `TEXT`, or `BLOB`) that exceeds the column's maximum length. The value is truncated to the column's maximum length.
- Inserting a value into a date or time column that is illegal for the data type. The column is set to the appropriate zero value for the type.

If you are using the C API, the information string can be obtained by invoking the `mysql_info()` function. See [Section 24.2.3.34](#), “`mysql_info()`”.

If `INSERT` inserts a row into a table that has an `AUTO_INCREMENT` column, you can find the value used for that column by using the SQL `LAST_INSERT_ID()` function. From within the C API, use the `mysql_insert_id()` function. However, you should note that the two functions do not always behave identically. The behavior of `INSERT` statements with respect to `AUTO_INCREMENT` columns is discussed further in [Section 12.10.3](#), “[Information Functions](#)”, and [Section 24.2.3.36](#), “`mysql_insert_id()`”.

The `INSERT` statement supports the following modifiers:

- If you use the `DELAYED` keyword, the server puts the row or rows to be inserted into a buffer, and the client issuing the `INSERT DELAYED` statement can then continue immediately. If the table is in use, the server holds the rows. When the table is free, the server begins inserting rows, checking periodically to see whether there are any new read requests for the table. If there are, the delayed row queue is suspended until the table becomes free again. See [Section 13.2.4.2](#), “[INSERT DELAYED Syntax](#)”.

`DELAYED` is ignored with `INSERT ... SELECT` or `INSERT ... ON DUPLICATE KEY UPDATE`.

- If you use the `LOW_PRIORITY` keyword, execution of the `INSERT` is delayed until no other clients are reading from the table. This includes other clients that began reading while existing clients are reading, and while the `INSERT LOW_PRIORITY` statement is waiting. It is possible, therefore, for a client that issues an `INSERT LOW_PRIORITY` statement to wait for a very long time (or even forever) in a read-heavy environment. (This is in contrast to `INSERT DELAYED`, which lets the client continue at once. Note that `LOW_PRIORITY` should normally not be used with `MyISAM` tables because doing so disables concurrent inserts. See [Section 7.3.3](#), “[Concurrent Inserts](#)”.
- If you specify `HIGH_PRIORITY`, it overrides the effect of the `--low-priority-updates` option if the server was started with that option. It also causes concurrent inserts not to be used.
- If you use the `IGNORE` keyword, errors that occur while executing the `INSERT` statement are treated as warnings instead. For example, without `IGNORE`, a row that duplicates an existing `UNIQUE` index or `PRIMARY KEY` value in the table causes a duplicate-key error and the statement is aborted. With `IGNORE`, the row still is not inserted, but no error is issued. Data conversions that would trigger errors abort the statement if `IGNORE` is not specified. With `IGNORE`, invalid values are adjusted to the closest values and inserted; warnings are produced but the statement does not abort. You can determine with the `mysql_info()` C API function how many rows were actually inserted into the table.
- If you specify `ON DUPLICATE KEY UPDATE`, and a row is inserted that would cause a duplicate value in a `UNIQUE` index or `PRIMARY KEY`, an `UPDATE` of the old row is performed. See [Section 13.2.4.3](#), “[INSERT ... ON DUPLICATE KEY UPDATE Syntax](#)”.

13.2.4.1. `INSERT ... SELECT` Syntax

```
INSERT [LOW_PRIORITY | HIGH_PRIORITY] [IGNORE]
  [INTO] tbl_name [(col_name,...)]
  SELECT ...
  [ ON DUPLICATE KEY UPDATE col_name=expr, ... ]
```

With `INSERT ... SELECT`, you can quickly insert many rows into a table from one or many tables. For example:

```
INSERT INTO tbl_temp2 (fld_id)
```

```
SELECT tbl_temp1.fld_order_id
FROM tbl_temp1 WHERE tbl_temp1.fld_order_id > 100;
```

The following conditions hold for a `INSERT ... SELECT` statements:

- Specify `IGNORE` to ignore rows that would cause duplicate-key violations.
- `DELAYED` is ignored with `INSERT ... SELECT`.
- The target table of the `INSERT` statement may appear in the `FROM` clause of the `SELECT` part of the query. (This was not possible in some older versions of MySQL.) In this case, MySQL creates a temporary table to hold the rows from the `SELECT` and then inserts those rows into the target table.
- `AUTO_INCREMENT` columns work as usual.
- To ensure that the binary log can be used to re-create the original tables, MySQL does not allow concurrent inserts for `INSERT ... SELECT` statements.
- Currently, you cannot insert into a table and select from the same table in a subquery.

In the values part of `ON DUPLICATE KEY UPDATE`, you can refer to columns in other tables, as long as you do not use `GROUP BY` in the `SELECT` part. One side effect is that you must qualify non-unique column names in the values part.

13.2.4.2. INSERT DELAYED Syntax

```
INSERT DELAYED ...
```

The `DELAYED` option for the `INSERT` statement is a MySQL extension to standard SQL that is very useful if you have clients that cannot or need not wait for the `INSERT` to complete. This is a common situation when you use MySQL for logging and you also periodically run `SELECT` and `UPDATE` statements that take a long time to complete.

When a client uses `INSERT DELAYED`, it gets an okay from the server at once, and the row is queued to be inserted when the table is not in use by any other thread.

Another major benefit of using `INSERT DELAYED` is that inserts from many clients are bundled together and written in one block. This is much faster than performing many separate inserts.

Note that `INSERT DELAYED` is slower than a normal `INSERT` if the table is not otherwise in use. There is also the additional overhead for the server to handle a separate thread for each table for which there are delayed rows. This means that you should use `INSERT DELAYED` only when you are really sure that you need it.

The queued rows are held only in memory until they are inserted into the table. This means that if you terminate `mysqld` forcibly (for example, with `kill -9`) or if `mysqld` dies unexpectedly, *any queued rows that have not been written to disk are lost*.

There are some constraints on the use of `DELAYED`:

- `INSERT DELAYED` works only with `MyISAM`, `MEMORY`, and `ARCHIVE` tables. See [Section 14.4, “The MyISAM Storage Engine”](#), [Section 14.7, “The MEMORY \(HEAP\) Storage Engine”](#), and [Section 14.10, “The ARCHIVE Storage Engine”](#).

For `MyISAM` tables, if there are no free blocks in the middle of the data file, concurrent `SELECT` and

`INSERT` statements are supported. Under these circumstances, you very seldom need to use `INSERT DELAYED` with `MyISAM`.

- `INSERT DELAYED` should be used only for `INSERT` statements that specify value lists. The server ignores `DELAYED` for `INSERT ... SELECT` or `INSERT ... ON DUPLICATE KEY UPDATE` statements.
- Because the `INSERT DELAYED` statement returns immediately, before the rows are inserted, you cannot use `LAST_INSERT_ID()` to get the `AUTO_INCREMENT` value that the statement might generate.
- `DELAYED` rows are not visible to `SELECT` statements until they actually have been inserted.
- `DELAYED` is ignored on slave replication servers because it could cause the slave to have different data than the master.
- Pending `INSERT DELAYED` statements are lost if a table is write locked and `ALTER TABLE` is used to modify the table structure.

The following describes in detail what happens when you use the `DELAYED` option to `INSERT` or `REPLACE`. In this description, the “thread” is the thread that received an `INSERT DELAYED` statement and “handler” is the thread that handles all `INSERT DELAYED` statements for a particular table.

- When a thread executes a `DELAYED` statement for a table, a handler thread is created to process all `DELAYED` statements for the table, if no such handler already exists.
- The thread checks whether the handler has previously acquired a `DELAYED` lock; if not, it tells the handler thread to do so. The `DELAYED` lock can be obtained even if other threads have a `READ` or `WRITE` lock on the table. However, the handler waits for all `ALTER TABLE` locks or `FLUSH TABLES` statements to finish, to ensure that the table structure is up to date.
- The thread executes the `INSERT` statement, but instead of writing the row to the table, it puts a copy of the final row into a queue that is managed by the handler thread. Any syntax errors are noticed by the thread and reported to the client program.
- The client cannot obtain from the server the number of duplicate rows or the `AUTO_INCREMENT` value for the resulting row, because the `INSERT` returns before the insert operation has been completed. (If you use the C API, the `mysql_info()` function does not return anything meaningful, for the same reason.)
- The binary log is updated by the handler thread when the row is inserted into the table. In case of multiple-row inserts, the binary log is updated when the first row is inserted.
- Each time that `delayed_insert_limit` rows are written, the handler checks whether any `SELECT` statements are still pending. If so, it allows these to execute before continuing.
- When the handler has no more rows in its queue, the table is unlocked. If no new `INSERT DELAYED` statements are received within `delayed_insert_timeout` seconds, the handler terminates.
- If more than `delayed_queue_size` rows are pending in a specific handler queue, the thread requesting `INSERT DELAYED` waits until there is room in the queue. This is done to ensure that `mysqld` does not use all memory for the delayed memory queue.
- The handler thread shows up in the MySQL process list with `delayed_insert` in the `Command` column. It is killed if you execute a `FLUSH TABLES` statement or kill it with `KILL thread_id`. However, before exiting, it first stores all queued rows into the table. During this time it does not ac-

cept any new `INSERT` statements from other threads. If you execute an `INSERT DELAYED` statement after this, a new handler thread is created.

Note that this means that `INSERT DELAYED` statements have higher priority than normal `INSERT` statements if there is an `INSERT DELAYED` handler running. Other update statements have to wait until the `INSERT DELAYED` queue is empty, someone terminates the handler thread (with `KILL thread_id`), or someone executes a `FLUSH TABLES`.

- The following status variables provide information about `INSERT DELAYED` statements:

Status Variable	Meaning
<code>Delayed_insert_threads</code>	Number of handler threads
<code>Delayed_writes</code>	Number of rows written with <code>INSERT DELAYED</code>
<code>Not_flushed_delayed_rows</code>	Number of rows waiting to be written

You can view these variables by issuing a `SHOW STATUS` statement or by executing a `mysqladmin extended-status` command.

13.2.4.3. `INSERT ... ON DUPLICATE KEY UPDATE` Syntax

If you specify `ON DUPLICATE KEY UPDATE`, and a row is inserted that would cause a duplicate value in a `UNIQUE` index or `PRIMARY KEY`, an `UPDATE` of the old row is performed. For example, if column `a` is declared as `UNIQUE` and contains the value `1`, the following two statements have identical effect:

```
INSERT INTO table (a,b,c) VALUES (1,2,3)
ON DUPLICATE KEY UPDATE c=c+1;

UPDATE table SET c=c+1 WHERE a=1;
```

The rows-affected value is 1 if the row is inserted as a new record and 2 if an existing record is updated.

If column `b` is also unique, the `INSERT` is equivalent to this `UPDATE` statement instead:

```
UPDATE table SET c=c+1 WHERE a=1 OR b=2 LIMIT 1;
```

If `a=1 OR b=2` matches several rows, only *one* row is updated. In general, you should try to avoid using an `ON DUPLICATE KEY` clause on tables with multiple unique indexes.

You can use the `VALUES(col_name)` function in the `UPDATE` clause to refer to column values from the `INSERT` portion of the `INSERT ... UPDATE` statement. In other words, `VALUES(col_name)` in the `UPDATE` clause refers to the value of `col_name` that would be inserted, had no duplicate-key conflict occurred. This function is especially useful in multiple-row inserts. The `VALUES()` function is meaningful only in `INSERT ... UPDATE` statements and returns `NULL` otherwise. Example:

```
INSERT INTO table (a,b,c) VALUES (1,2,3),(4,5,6)
ON DUPLICATE KEY UPDATE c=VALUES(a)+VALUES(b);
```

That statement is identical to the following two statements:

```
INSERT INTO table (a,b,c) VALUES (1,2,3)
ON DUPLICATE KEY UPDATE c=3;
INSERT INTO table (a,b,c) VALUES (4,5,6)
ON DUPLICATE KEY UPDATE c=9;
```

If a table contains an `AUTO_INCREMENT` column and `INSERT ... UPDATE` inserts a row, the `LAST_INSERT_ID()` function returns the `AUTO_INCREMENT` value. If the statement updates a row instead, `LAST_INSERT_ID()` is not meaningful. However, you can work around this by using `LAST_INSERT_ID(expr)`. Suppose that `id` is the `AUTO_INCREMENT` column. To make `LAST_INSERT_ID()` meaningful for updates, insert rows as follows:

```
INSERT INTO table (a,b,c) VALUES (1,2,3)
ON DUPLICATE KEY UPDATE id=LAST_INSERT_ID(id), c=3;
```

The `DELAYED` option is ignored when you use `ON DUPLICATE KEY UPDATE`.

13.2.5. LOAD DATA INFILE Syntax

```
LOAD DATA [LOW_PRIORITY | CONCURRENT] [LOCAL] INFILE 'file_name'
[REPLACE | IGNORE]
INTO TABLE tbl_name
[FIELDS
  [TERMINATED BY 'string']
  [[OPTIONALLY] ENCLOSED BY 'char']
  [ESCAPED BY 'char']
]
[LINES
  [STARTING BY 'string']
  [TERMINATED BY 'string']
]
[IGNORE number LINES]
[(col_name_or_user_var,...)]
[SET col_name = expr,...]
```

The `LOAD DATA INFILE` statement reads rows from a text file into a table at a very high speed. The filename must be given as a literal string.

`LOAD DATA INFILE` is the complement of `SELECT ... INTO OUTFILE`. (See [Section 13.2.7, “SELECT Syntax”](#).) To write data from a table to a file, use `SELECT ... INTO OUTFILE`. To read the file back into a table, use `LOAD DATA INFILE`. The syntax of the `FIELDS` and `LINES` clauses is the same for both statements. Both clauses are optional, but `FIELDS` must precede `LINES` if both are specified.

For more information about the efficiency of `INSERT` versus `LOAD DATA INFILE` and speeding up `LOAD DATA INFILE`, see [Section 7.2.16, “Speed of INSERT Statements”](#).

The character set indicated by the `character_set_database` system variable is used to interpret the information in the file. `SET NAMES` and the setting of `character_set_client` do not affect interpretation of input.

Note that it is currently not possible to load data files that use the `ucs2` character set.

As of MySQL 5.1.6, the `character_set_filesystem` system variable controls the interpretation of the filename.

You can also load data files by using the `mysqlimport` utility; it operates by sending a `LOAD DATA INFILE` statement to the server. The `--local` option causes `mysqlimport` to read data files from the client host. You can specify the `--compress` option to get better performance over slow networks if the client and server support the compressed protocol. See [Section 8.13, “mysqlimport — A Data Import Program”](#).

If you use `LOW_PRIORITY`, execution of the `LOAD DATA` statement is delayed until no other clients are reading from the table.

If you specify `CONCURRENT` with a `MyISAM` table that satisfies the condition for concurrent inserts (that is, it contains no free blocks in the middle), other threads can retrieve data from the table while

`LOAD DATA` is executing. Using this option affects the performance of `LOAD DATA` a bit, even if no other thread is using the table at the same time.

The `LOCAL` keyword, if specified, is interpreted with respect to the client end of the connection:

- If `LOCAL` is specified, the file is read by the client program on the client host and sent to the server. The file can be given as a full pathname to specify its exact location. If given as a relative pathname, the name is interpreted relative to the directory in which the client program was started.
- If `LOCAL` is not specified, the file must be located on the server host and is read directly by the server. The server uses the following rules to locate the file:
 - If the filename is an absolute pathname, the server uses it as given.
 - If the filename is a relative pathname with one or more leading components, the server searches for the file relative to the server's data directory.
 - If a filename with no leading components is given, the server looks for the file in the database directory of the default database.

Note that, in the non-`LOCAL` case, these rules mean that a file named as `./myfile.txt` is read from the server's data directory, whereas the file named as `myfile.txt` is read from the database directory of the default database. For example, if `db1` is the default database, the following `LOAD DATA` statement reads the file `data.txt` from the database directory for `db1`, even though the statement explicitly loads the file into a table in the `db2` database:

```
LOAD DATA INFILE 'data.txt' INTO TABLE db2.my_table;
```

Windows pathnames are specified using forward slashes rather than backslashes. If you do use backslashes, you must double them.

For security reasons, when reading text files located on the server, the files must either reside in the database directory or be readable by all. Also, to use `LOAD DATA INFILE` on server files, you must have the `FILE` privilege. See [Section 5.8.3, “Privileges Provided by MySQL”](#).

Using `LOCAL` is a bit slower than letting the server access the files directly, because the contents of the file must be sent over the connection by the client to the server. On the other hand, you do not need the `FILE` privilege to load local files.

`LOCAL` works only if your server and your client both have been enabled to allow it. For example, if `mysqld` was started with `--local-infile=0`, `LOCAL` does not work. See [Section 5.7.4, “Security Issues with LOAD DATA LOCAL”](#).

On Unix, if you need `LOAD DATA` to read from a pipe, you can use the following technique (here we load the listing of the `/` directory into a table):

```
mkfifo /mysql/db/x/x
chmod 666 /mysql/db/x/x
find / -ls > /mysql/db/x/x
mysql -e "LOAD DATA INFILE 'x' INTO TABLE x" x
```

The `REPLACE` and `IGNORE` keywords control handling of input rows that duplicate existing rows on unique key values:

- If you specify `REPLACE`, input rows replace existing rows. In other words, rows that have the same value for a primary key or unique index as an existing row. See [Section 13.2.6, “REPLACE Syntax”](#).

- If you specify `IGNORE`, input rows that duplicate an existing row on a unique key value are skipped. If you do not specify either option, the behavior depends on whether the `LOCAL` keyword is specified. Without `LOCAL`, an error occurs when a duplicate key value is found, and the rest of the text file is ignored. With `LOCAL`, the default behavior is the same as if `IGNORE` is specified; this is because the server has no way to stop transmission of the file in the middle of the operation.

If you want to ignore foreign key constraints during the load operation, you can issue a `SET FOREIGN_KEY_CHECKS=0` statement before executing `LOAD DATA`.

If you use `LOAD DATA INFILE` on an empty `MyISAM` table, all non-unique indexes are created in a separate batch (as for `REPAIR TABLE`). Normally, this makes `LOAD DATA INFILE` much faster when you have many indexes. In some extreme cases, you can create the indexes even faster by turning them off with `ALTER TABLE ... DISABLE KEYS` before loading the file into the table and using `ALTER TABLE ... ENABLE KEYS` to re-create the indexes after loading the file. See [Section 7.2.16, “Speed of INSERT Statements”](#).

For both the `LOAD DATA INFILE` and `SELECT ... INTO OUTFILE` statements, the syntax of the `FIELDS` and `LINES` clauses is the same. Both clauses are optional, but `FIELDS` must precede `LINES` if both are specified.

If you specify a `FIELDS` clause, each of its subclauses (`TERMINATED BY`, `[OPTIONALLY] ENCLOSED BY`, and `ESCAPED BY`) is also optional, except that you must specify at least one of them.

If you specify no `FIELDS` clause, the defaults are the same as if you had written this:

```
FIELDS TERMINATED BY '\t' ENCLOSED BY '' ESCAPED BY '\\'
```

If you specify no `LINES` clause, the defaults are the same as if you had written this:

```
LINES TERMINATED BY '\n' STARTING BY ''
```

In other words, the defaults cause `LOAD DATA INFILE` to act as follows when reading input:

- Look for line boundaries at newlines.
- Do not skip over any line prefix.
- Break lines into fields at tabs.
- Do not expect fields to be enclosed within any quoting characters.
- Interpret occurrences of tab, newline, or `'\'` preceded by `'\'` as literal characters that are part of field values.

Conversely, the defaults cause `SELECT ... INTO OUTFILE` to act as follows when writing output:

- Write tabs between fields.
- Do not enclose fields within any quoting characters.
- Use `'\'` to escape instances of tab, newline, or `'\'` that occur within field values.
- Write newlines at the ends of lines.

Backslash is the MySQL escape character within strings, so to write `FIELDS ESCAPED BY '\\'`, you must specify two backslashes for the value to be interpreted as a single backslash.

Note: If you have generated the text file on a Windows system, you might have to use `LINES TERMINATED BY '\\r\\n'` to read the file properly, because Windows programs typically use two characters as a line terminator. Some programs, such as `WordPad`, might use `\\r` as a line terminator when writing files. To read such files, use `LINES TERMINATED BY '\\r'`.

If all the lines you want to read in have a common prefix that you want to ignore, you can use `LINES STARTING BY 'prefix_string'` to skip over the prefix, *and anything before it*. If a line does not include the prefix, the entire line is skipped. Suppose that you issue the following statement:

```
LOAD DATA INFILE '/tmp/test.txt' INTO TABLE test
  FIELDS TERMINATED BY ',' LINES STARTING BY 'xxx';
```

If the data file looks like this:

```
xxx"abc",1
something xxx"def",2
"ghi",3
```

The resulting rows will be `("abc",1)` and `("def",2)`. The third row in the file is skipped because it does not contain the prefix.

The `IGNORE number LINES` option can be used to ignore lines at the start of the file. For example, you can use `IGNORE 1 LINES` to skip over an initial header line containing column names:

```
LOAD DATA INFILE '/tmp/test.txt' INTO TABLE test IGNORE 1 LINES;
```

When you use `SELECT ... INTO OUTFILE` in tandem with `LOAD DATA INFILE` to write data from a database into a file and then read the file back into the database later, the field- and line-handling options for both statements must match. Otherwise, `LOAD DATA INFILE` will not interpret the contents of the file properly. Suppose that you use `SELECT ... INTO OUTFILE` to write a file with fields delimited by commas:

```
SELECT * INTO OUTFILE 'data.txt'
  FIELDS TERMINATED BY ','
  FROM table2;
```

To read the comma-delimited file back in, the correct statement would be:

```
LOAD DATA INFILE 'data.txt' INTO TABLE table2
  FIELDS TERMINATED BY ',';
```

If instead you tried to read in the file with the statement shown following, it wouldn't work because it instructs `LOAD DATA INFILE` to look for tabs between fields:

```
LOAD DATA INFILE 'data.txt' INTO TABLE table2
  FIELDS TERMINATED BY '\\t';
```

The likely result is that each input line would be interpreted as a single field.

`LOAD DATA INFILE` can be used to read files obtained from external sources. For example, many programs can export data in comma-separated values (CSV) format, such that lines have fields separated by commas and enclosed within double quotes. If lines in such a file are terminated by newlines, the statement shown here illustrates the field- and line-handling options you would use to load the file:

```
LOAD DATA INFILE 'data.txt' INTO TABLE tbl_name
  FIELDS TERMINATED BY ',' ENCLOSED BY '"'
```

```

LINES TERMINATED BY '\n';

```

Any of the field- or line-handling options can specify an empty string (' '). If not empty, the **FIELDS [OPTIONALLY] ENCLOSED BY** and **FIELDS ESCAPED BY** values must be a single character. The **FIELDS TERMINATED BY**, **LINES STARTING BY**, and **LINES TERMINATED BY** values can be more than one character. For example, to write lines that are terminated by carriage return/line-feed pairs, or to read a file containing such lines, specify a **LINES TERMINATED BY '\r\n'** clause.

To read a file containing jokes that are separated by lines consisting of `%%`, you can do this

```

CREATE TABLE jokes
  (a INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
   joke TEXT NOT NULL);
LOAD DATA INFILE '/tmp/jokes.txt' INTO TABLE jokes
  FIELDS TERMINATED BY ' '
  LINES TERMINATED BY '\n%%\n' (joke);

```

FIELDS [OPTIONALLY] ENCLOSED BY controls quoting of fields. For output (**SELECT ... INTO OUTFILE**), if you omit the word **OPTIONALLY**, all fields are enclosed by the **ENCLOSED BY** character. An example of such output (using a comma as the field delimiter) is shown here:

```

"1","a string","100.20"
"2","a string containing a , comma","102.20"
"3","a string containing a \" quote","102.20"
"4","a string containing a \", quote and comma","102.20"

```

If you specify **OPTIONALLY**, the **ENCLOSED BY** character is used only to enclose values from columns that have a string data type (such as **CHAR**, **BINARY**, **TEXT**, or **ENUM**):

```

1,"a string",100.20
2,"a string containing a , comma",102.20
3,"a string containing a \" quote",102.20
4,"a string containing a \", quote and comma",102.20

```

Note that occurrences of the **ENCLOSED BY** character within a field value are escaped by prefixing them with the **ESCAPED BY** character. Also note that if you specify an empty **ESCAPED BY** value, it is possible to inadvertently generate output that cannot be read properly by **LOAD DATA INFILE**. For example, the preceding output just shown would appear as follows if the escape character is empty. Observe that the second field in the fourth line contains a comma following the quote, which (erroneously) appears to terminate the field:

```

1,"a string",100.20
2,"a string containing a , comma",102.20
3,"a string containing a " quote",102.20
4,"a string containing a ", quote and comma",102.20

```

For input, the **ENCLOSED BY** character, if present, is stripped from the ends of field values. (This is true regardless of whether **OPTIONALLY** is specified; **OPTIONALLY** has no effect on input interpretation.) Occurrences of the **ENCLOSED BY** character preceded by the **ESCAPED BY** character are interpreted as part of the current field value.

If the field begins with the **ENCLOSED BY** character, instances of that character are recognized as terminating a field value only if followed by the field or line **TERMINATED BY** sequence. To avoid ambiguity, occurrences of the **ENCLOSED BY** character within a field value can be doubled and are interpreted as a single instance of the character. For example, if **ENCLOSED BY ' '** is specified, quotes are handled as shown here:

```

"The ""BIG"" boss" -> The "BIG" boss
The "BIG" boss    -> The "BIG" boss
The ""BIG"" boss  -> The ""BIG"" boss

```

`FIELDS ESCAPED BY` controls how to write or read special characters. If the `FIELDS ESCAPED BY` character is not empty, it is used to prefix the following characters on output:

- The `FIELDS ESCAPED BY` character
- The `FIELDS [OPTIONALLY] ENCLOSED BY` character
- The first character of the `FIELDS TERMINATED BY` and `LINES TERMINATED BY` values
- ASCII 0 (what is actually written following the escape character is ASCII '0', not a zero-valued byte)

If the `FIELDS ESCAPED BY` character is empty, no characters are escaped and `NULL` is output as `NULL`, not `\N`. It is probably not a good idea to specify an empty escape character, particularly if field values in your data contain any of the characters in the list just given.

For input, if the `FIELDS ESCAPED BY` character is not empty, occurrences of that character are stripped and the following character is taken literally as part of a field value. The exceptions are an escaped '0' or 'N' (for example, `\0` or `\N` if the escape character is `'\'`). These sequences are interpreted as ASCII NUL (a zero-valued byte) and `NULL`. The rules for `NULL` handling are described later in this section.

For more information about `'\'`-escape syntax, see [Section 9.1, "Literal Values"](#).

In certain cases, field- and line-handling options interact:

- If `LINES TERMINATED BY` is an empty string and `FIELDS TERMINATED BY` is non-empty, lines are also terminated with `FIELDS TERMINATED BY`.
- If the `FIELDS TERMINATED BY` and `FIELDS ENCLOSED BY` values are both empty (' '), a fixed-row (non-delimited) format is used. With fixed-row format, no delimiters are used between fields (but you can still have a line terminator). Instead, column values are read and written using a field width wide enough to hold all values in the field. For `TINYINT`, `SMALLINT`, `MEDIUMINT`, `INT`, and `BIGINT`, the field widths are 4, 6, 8, 11, and 20, respectively, no matter what the declared display width is.

`LINES TERMINATED BY` is still used to separate lines. If a line does not contain all fields, the rest of the columns are set to their default values. If you do not have a line terminator, you should set this to ' '. In this case, the text file must contain all fields for each row.

Fixed-row format also affects handling of `NULL` values, as described later. Note that fixed-size format does not work if you are using a multi-byte character set.

Handling of `NULL` values varies according to the `FIELDS` and `LINES` options in use:

- For the default `FIELDS` and `LINES` values, `NULL` is written as a field value of `\N` for output, and a field value of `\N` is read as `NULL` for input (assuming that the `ESCAPED BY` character is `'\'`).
- If `FIELDS ENCLOSED BY` is not empty, a field containing the literal word `NULL` as its value is read as a `NULL` value. This differs from the word `NULL` enclosed within `FIELDS ENCLOSED BY` characters, which is read as the string `'NULL'`.
- If `FIELDS ESCAPED BY` is empty, `NULL` is written as the word `NULL`.

- With fixed-row format (which is used when `FIELDS TERMINATED BY` and `FIELDS ENCLOSED BY` are both empty), `NULL` is written as an empty string. Note that this causes both `NULL` values and empty strings in the table to be indistinguishable when written to the file because both are written as empty strings. If you need to be able to tell the two apart when reading the file back in, you should not use fixed-row format.

An attempt to load `NULL` into a `NOT NULL` column causes assignment of the implicit default value for the column's data type and a warning, or an error in strict SQL mode. Implicit default values are discussed in [Section 11.1.4, "Data Type Default Values"](#).

Some cases are not supported by `LOAD DATA INFILE`:

- Fixed-size rows (`FIELDS TERMINATED BY` and `FIELDS ENCLOSED BY` both empty) and `BLOB` or `TEXT` columns.
- If you specify one separator that is the same as or a prefix of another, `LOAD DATA INFILE` cannot interpret the input properly. For example, the following `FIELDS` clause would cause problems:

```
FIELDS TERMINATED BY '' ENCLOSED BY ''
```

- If `FIELDS ESCAPED BY` is empty, a field value that contains an occurrence of `FIELDS ENCLOSED BY` or `LINES TERMINATED BY` followed by the `FIELDS TERMINATED BY` value causes `LOAD DATA INFILE` to stop reading a field or line too early. This happens because `LOAD DATA INFILE` cannot properly determine where the field or line value ends.

The following example loads all columns of the `persondata` table:

```
LOAD DATA INFILE 'persondata.txt' INTO TABLE persondata;
```

By default, when no column list is provided at the end of the `LOAD DATA INFILE` statement, input lines are expected to contain a field for each table column. If you want to load only some of a table's columns, specify a column list:

```
LOAD DATA INFILE 'persondata.txt' INTO TABLE persondata (col1,col2,...);
```

You must also specify a column list if the order of the fields in the input file differs from the order of the columns in the table. Otherwise, MySQL cannot tell how to match input fields with table columns.

The column list can contain either column names or user variables. With user variables, the `SET` clause enables you to perform transformations on their values before assigning the result to columns.

User variables in the `SET` clause can be used in several ways. The following example uses the first input column directly for the value of `t1.column1`, and assigns the second input column to a user variable that is subjected to a division operation before being used for the value of `t1.column2`:

```
LOAD DATA INFILE 'file.txt'
  INTO TABLE t1
  (column1, @var1)
  SET column2 = @var1/100;
```

The `SET` clause can be used to supply values not derived from the input file. The following statement sets `column3` to the current date and time:

```
LOAD DATA INFILE 'file.txt'
  INTO TABLE t1
  (column1, column2)
```

```
SET column3 = CURRENT_TIMESTAMP;
```

You can also discard an input value by assigning it to a user variable and not assigning the variable to a table column:

```
LOAD DATA INFILE 'file.txt'
  INTO TABLE t1
  (column1, @dummy, column2, @dummy, column3);
```

Use of the column/variable list and `SET` clause is subject to the following restrictions:

- Assignments in the `SET` clause should have only column names on the left hand side of assignment operators.
- You can use subqueries in the right hand side of `SET` assignments. A subquery that returns a value to be assigned to a column may be a scalar subquery only. Also, you cannot use a subquery to select from the table that is being loaded.
- Lines ignored by an `IGNORE` clause are not processed for the column/variable list or `SET` clause.
- User variables cannot be used when loading data with fixed-row format because user variables do not have a display width.

When processing an input line, `LOAD DATA` splits it into fields and uses the values according to the column/variable list and the `SET` clause, if they are present. Then the resulting row is inserted into the table. If there are `BEFORE INSERT` or `AFTER INSERT` triggers for the table, they are activated before or after inserting the row, respectively.

If an input line has too many fields, the extra fields are ignored and the number of warnings is incremented.

If an input line has too few fields, the table columns for which input fields are missing are set to their default values. Default value assignment is described in [Section 11.1.4, “Data Type Default Values”](#).

An empty field value is interpreted differently than if the field value is missing:

- For string types, the column is set to the empty string.
- For numeric types, the column is set to 0.
- For date and time types, the column is set to the appropriate “zero” value for the type. See [Section 11.3, “Date and Time Types”](#).

These are the same values that result if you assign an empty string explicitly to a string, numeric, or date or time type explicitly in an `INSERT` or `UPDATE` statement.

`TIMESTAMP` columns are set to the current date and time only if there is a `NULL` value for the column (that is, `\N`), or if the `TIMESTAMP` column's default value is the current timestamp and it is omitted from the field list when a field list is specified.

`LOAD DATA INFILE` regards all input as strings, so you cannot use numeric values for `ENUM` or `SET` columns the way you can with `INSERT` statements. All `ENUM` and `SET` values must be specified as strings.

`BIT` values cannot be loaded using binary notation (for example, `b'011010'`). To work around this,

specify the values as regular integers and use the `SET` clause to convert them so that MySQL performs a numeric type conversion and loads them into the `BIT` column properly:

```
shell> cat /tmp/bit_test.txt
2
127
shell> mysql test
mysql> LOAD DATA INFILE '/tmp/bit_test.txt'
-> INTO TABLE bit_test (@var1) SET b= CAST(@var1 AS SIGNED);
Query OK, 2 rows affected (0.00 sec)
Records: 2 Deleted: 0 Skipped: 0 Warnings: 0

mysql> SELECT BIN(b+0) FROM bit_test;
+-----+
| bin(b+0) |
+-----+
| 10       |
| 1111111 |
+-----+
2 rows in set (0.00 sec)
```

When the `LOAD DATA INFILE` statement finishes, it returns an information string in the following format:

```
Records: 1 Deleted: 0 Skipped: 0 Warnings: 0
```

If you are using the C API, you can get information about the statement by calling the `mysql_info()` function. See [Section 24.2.3.34](#), “`mysql_info()`”.

Warnings occur under the same circumstances as when values are inserted via the `INSERT` statement (see [Section 13.2.4](#), “`INSERT Syntax`”), except that `LOAD DATA INFILE` also generates warnings when there are too few or too many fields in the input row. The warnings are not stored anywhere; the number of warnings can be used only as an indication of whether everything went well.

You can use `SHOW WARNINGS` to get a list of the first `max_error_count` warnings as information about what went wrong. See [Section 13.5.4.30](#), “`SHOW WARNINGS Syntax`”.

13.2.6. REPLACE Syntax

```
REPLACE [LOW_PRIORITY | DELAYED]
  [INTO] tbl_name [(col_name,...)]
  VALUES ({expr | DEFAULT},...),(...),...
```

Or:

```
REPLACE [LOW_PRIORITY | DELAYED]
  [INTO] tbl_name
  SET col_name={expr | DEFAULT}, ...
```

Or:

```
REPLACE [LOW_PRIORITY | DELAYED]
  [INTO] tbl_name [(col_name,...)]
  SELECT ...
```

`REPLACE` works exactly like `INSERT`, except that if an old row in the table has the same value as a new row for a `PRIMARY KEY` or a `UNIQUE` index, the old row is deleted before the new row is inserted. See [Section 13.2.4](#), “`INSERT Syntax`”.

`REPLACE` is a MySQL extension to the SQL standard. It either inserts, or *deletes* and inserts. For another MySQL extension to standard SQL — that either inserts or *updates* — see [Section 13.2.4.3](#), “`INSERT ... ON DUPLICATE KEY UPDATE Syntax`”.

Note that unless the table has a `PRIMARY KEY` or `UNIQUE` index, using a `REPLACE` statement makes no sense. It becomes equivalent to `INSERT`, because there is no index to be used to determine whether a new row duplicates another.

Values for all columns are taken from the values specified in the `REPLACE` statement. Any missing columns are set to their default values, just as happens for `INSERT`. You cannot refer to values from the current row and use them in the new row. If you use an assignment such as `SET col_name = col_name + 1`, the reference to the column name on the right hand side is treated as `DEFAULT(col_name)`, so the assignment is equivalent to `SET col_name = DEFAULT(col_name) + 1`.

To use `REPLACE`, you must have both the `INSERT` and `DELETE` privileges for the table.

The `REPLACE` statement returns a count to indicate the number of rows affected. This is the sum of the rows deleted and inserted. If the count is 1 for a single-row `REPLACE`, a row was inserted and no rows were deleted. If the count is greater than 1, one or more old rows were deleted before the new row was inserted. It is possible for a single row to replace more than one old row if the table contains multiple unique indexes and the new row duplicates values for different old rows in different unique indexes.

The affected-rows count makes it easy to determine whether `REPLACE` only added a row or whether it also replaced any rows: Check whether the count is 1 (added) or greater (replaced).

If you are using the C API, the affected-rows count can be obtained using the `mysql_affected_rows()` function.

Currently, you cannot replace into a table and select from the same table in a subquery.

MySQL uses the following algorithm for `REPLACE` (and `LOAD DATA ... REPLACE`):

1. Try to insert the new row into the table
2. While the insertion fails because a duplicate-key error occurs for a primary key or unique index:
 - a. Delete from the table the conflicting row that has the duplicate key value
 - b. Try again to insert the new row into the table

13.2.7. `SELECT` Syntax

```
SELECT
  [ALL | DISTINCT | DISTINCTROW ]
  [HIGH_PRIORITY]
  [STRAIGHT_JOIN]
  [SQL_SMALL_RESULT] [SQL_BIG_RESULT] [SQL_BUFFER_RESULT]
  [SQL_CACHE | SQL_NO_CACHE] [SQL_CALC_FOUND_ROWS]
  select_expr, ...
  [FROM table_references
  [WHERE where_condition]
  [GROUP BY {col_name | expr | position}
  [ASC | DESC], ... [WITH ROLLUP]]
  [HAVING where_condition]
  [ORDER BY {col_name | expr | position}
  [ASC | DESC], ...]
  [LIMIT {{offset,} row_count | row_count OFFSET offset}]
  [PROCEDURE procedure_name(argument_list)]
  [INTO OUTFILE 'file_name' export_options
  | INTO DUMPFILE 'file_name'
  | INTO @var_name [, @var_name]]
  [FOR UPDATE | LOCK IN SHARE MODE]]
```

`SELECT` is used to retrieve rows selected from one or more tables, and can include `UNION` statements

and subqueries. See [Section 13.2.7.2, “UNION Syntax”](#), and [Section 13.2.8, “Subquery Syntax”](#).

The most commonly used clauses of `SELECT` statements are these:

- Each *select_expr* indicates a column that you want to retrieve. There must be at least one *select_expr*.
- *table_references* indicates the table or tables from which to retrieve rows. Its syntax is described in [Section 13.2.7.1, “JOIN Syntax”](#).
- The `WHERE` clause, if given, indicates the condition or conditions that rows must satisfy to be selected. *where_condition* is an expression that evaluates to true for each row to be selected. The statement selects all rows if there is no `WHERE` clause.

In the `WHERE` clause, you can use any of the functions and operators that MySQL supports, except for aggregate (summary) functions. See [Chapter 12, *Functions and Operators*](#).

`SELECT` can also be used to retrieve rows computed without reference to any table.

For example:

```
mysql> SELECT 1 + 1;
-> 2
```

You are allowed to specify `DUAL` as a dummy table name in situations where no tables are referenced:

```
mysql> SELECT 1 + 1 FROM DUAL;
-> 2
```

`DUAL` is purely for the convenience of people who require that all `SELECT` statements should have `FROM` and possibly other clauses. MySQL may ignore the clauses. MySQL does not require `FROM DUAL` if no tables are referenced.

In general, clauses used must be given in exactly the order shown in the syntax description. For example, a `HAVING` clause must come after any `GROUP BY` clause and before any `ORDER BY` clause. The exception is that the `INTO` clause can appear either as shown in the syntax description or immediately preceding the `FROM` clause.

- A *select_expr* can be given an alias using `AS alias_name`. The alias is used as the expression's column name and can be used in `GROUP BY`, `ORDER BY`, or `HAVING` clauses. For example:

```
SELECT CONCAT(last_name, ', ', first_name) AS full_name
FROM mytable ORDER BY full_name;
```

The `AS` keyword is optional when aliasing a *select_expr*. The preceding example could have been written like this:

```
SELECT CONCAT(last_name, ', ', first_name) full_name
FROM mytable ORDER BY full_name;
```

However, because the `AS` is optional, a subtle problem can occur if you forget the comma between two *select_expr* expressions: MySQL interprets the second as an alias name. For example, in the following statement, `columnb` is treated as an alias name:

```
SELECT columna columnb FROM mytable;
```

For this reason, it is good practice to be in the habit of using `AS` explicitly when specifying column aliases.

- It is not allowable to use a column alias in a `WHERE` clause, because the column value might not yet be determined when the `WHERE` clause is executed. See [Section A.5.4, “Problems with Column Aliases”](#).
- The `FROM table_references` clause indicates the table or tables from which to retrieve rows. If you name more than one table, you are performing a join. For information on join syntax, see [Section 13.2.7.1, “JOIN Syntax”](#). For each table specified, you can optionally specify an alias.

```
tbl_name [[AS] alias]
        [{USE|IGNORE|FORCE} INDEX (key_list)]
```

The use of `USE INDEX`, `IGNORE INDEX`, `FORCE INDEX` to give the optimizer hints about how to choose indexes is described in [Section 13.2.7.1, “JOIN Syntax”](#).

You can use `SET max_seeks_for_key=value` as an alternative way to force MySQL to prefer key scans instead of table scans. See [Section 5.2.3, “System Variables”](#).

- You can refer to a table within the default database as `tbl_name`, or as `db_name.tbl_name` to specify a database explicitly. You can refer to a column as `col_name`, `tbl_name.col_name`, or `db_name.tbl_name.col_name`. You need not specify a `tbl_name` or `db_name.tbl_name` prefix for a column reference unless the reference would be ambiguous. See [Section 9.2.1, “Identifier Qualifiers”](#), for examples of ambiguity that require the more explicit column reference forms.
- A table reference can be aliased using `tbl_name AS alias_name` or `tbl_name alias_name`:

```
SELECT t1.name, t2.salary FROM employee AS t1, info AS t2
        WHERE t1.name = t2.name;

SELECT t1.name, t2.salary FROM employee t1, info t2
        WHERE t1.name = t2.name;
```

- Columns selected for output can be referred to in `ORDER BY` and `GROUP BY` clauses using column names, column aliases, or column positions. Column positions are integers and begin with 1:

```
SELECT college, region, seed FROM tournament
        ORDER BY region, seed;

SELECT college, region AS r, seed AS s FROM tournament
        ORDER BY r, s;

SELECT college, region, seed FROM tournament
        ORDER BY 2, 3;
```

To sort in reverse order, add the `DESC` (descending) keyword to the name of the column in the `ORDER BY` clause that you are sorting by. The default is ascending order; this can be specified explicitly using the `ASC` keyword.

Use of column positions is deprecated because the syntax has been removed from the SQL standard.

- If you use `GROUP BY`, output rows are sorted according to the `GROUP BY` columns as if you had an `ORDER BY` for the same columns. To avoid the overhead of sorting that `GROUP BY` produces, add `ORDER BY NULL`:

```
SELECT a, COUNT(b) FROM test_table GROUP BY a ORDER BY NULL;
```

- MySQL extends the `GROUP BY` clause so that you can also specify `ASC` and `DESC` after columns named in the clause:

```
SELECT a, COUNT(b) FROM test_table GROUP BY a DESC;
```

- MySQL extends the use of `GROUP BY` to allow selecting fields that are not mentioned in the `GROUP BY` clause. If you are not getting the results that you expect from your query, please read the description of `GROUP BY` found in [Section 12.11, “Functions and Modifiers for Use with GROUP BY Clauses”](#).
- `GROUP BY` allows a `WITH ROLLUP` modifier. See [Section 12.11.2, “GROUP BY Modifiers”](#).
- The `HAVING` clause is applied nearly last, just before items are sent to the client, with no optimization. (`LIMIT` is applied after `HAVING`.)

The SQL standard requires that `HAVING` must reference only columns in the `GROUP BY` clause or columns used in aggregate functions. However, MySQL supports an extension to this behavior, and allows `HAVING` to refer to columns in the `SELECT` list and columns in outer subqueries as well.

If the `HAVING` clause refers to a column that is ambiguous, a warning occurs. In the following statement, `col2` is ambiguous because it is used as both an alias and a column name:

```
SELECT COUNT(col1) AS col2 FROM t GROUP BY col2 HAVING col2 = 2;
```

Preference is given to standard SQL behavior, so if a `HAVING` column name is used both in `GROUP BY` and as an aliased column in the output column list, preference is given to the column in the `GROUP BY` column.

- Do not use `HAVING` for items that should be in the `WHERE` clause. For example, do not write the following:

```
SELECT col_name FROM tbl_name HAVING col_name > 0;
```

Write this instead:

```
SELECT col_name FROM tbl_name WHERE col_name > 0;
```

- The `HAVING` clause can refer to aggregate functions, which the `WHERE` clause cannot:

```
SELECT user, MAX(salary) FROM users
GROUP BY user HAVING MAX(salary) > 10;
```

(This did not work in some older versions of MySQL.)

- MySQL allows duplicate column names. That is, there can be more than one `select_expr` with the same name. This is an extension to standard SQL. Because MySQL also allows `GROUP BY` and `HAVING` to refer to `select_expr` values, this can result in an ambiguity:

```
SELECT 12 AS a, a FROM t GROUP BY a;
```

In that statement, both columns have the name `a`. To ensure that the correct column is used for grouping, use different names for each `select_expr`.

- MySQL resolves unqualified column or alias references in `ORDER BY` clauses by searching in the `select_expr` values, then in the columns of the tables in the `FROM` clause. For `GROUP BY` or `HAVING` clauses, it searches the `FROM` clause before searching in the `select_expr` values. (For `GROUP BY` and `HAVING`, this differs from the pre-MySQL 5.0 behavior that used the same rules as

for `ORDER BY`.)

- The `LIMIT` clause can be used to constrain the number of rows returned by the `SELECT` statement. `LIMIT` takes one or two numeric arguments, which must both be non-negative integer constants (except when using prepared statements).

With two arguments, the first argument specifies the offset of the first row to return, and the second specifies the maximum number of rows to return. The offset of the initial row is 0 (not 1):

```
SELECT * FROM tbl LIMIT 5,10; # Retrieve rows 6-15
```

To retrieve all rows from a certain offset up to the end of the result set, you can use some large number for the second parameter. This statement retrieves all rows from the 96th row to the last:

```
SELECT * FROM tbl LIMIT 95,18446744073709551615;
```

With one argument, the value specifies the number of rows to return from the beginning of the result set:

```
SELECT * FROM tbl LIMIT 5; # Retrieve first 5 rows
```

In other words, `LIMIT row_count` is equivalent to `LIMIT 0, row_count`.

For prepared statements, you can use placeholders. The following statements will return one row from the `tbl` table:

```
SET @a=1;
PREPARE STMT FROM 'SELECT * FROM tbl LIMIT ?';
EXECUTE STMT USING @a;
```

The following statements will return the second to sixth row from the `tbl` table:

```
SET @skip=1; SET @numrows=5;
PREPARE STMT FROM 'SELECT * FROM tbl LIMIT ?, ?';
EXECUTE STMT USING @skip, @numrows;
```

For compatibility with PostgreSQL, MySQL also supports the `LIMIT row_count OFFSET offset` syntax.

- The `SELECT ... INTO OUTFILE 'file_name'` form of `SELECT` writes the selected rows to a file. The file is created on the server host, so you must have the `FILE` privilege to use this syntax. `file_name` cannot be an existing file, which among other things prevents files such as `/etc/passwd` and database tables from being destroyed. As of MySQL 5.1.6, the `character_set_filesystem` system variable controls the interpretation of the filename.

The `SELECT ... INTO OUTFILE` statement is intended primarily to let you very quickly dump a table to a text file on the server machine. If you want to create the resulting file on some client host other than the server host, you cannot use `SELECT ... INTO OUTFILE`. In that case, you should instead use a command such as `mysql -e "SELECT ..." > file_name` to generate the file on the client host.

`SELECT ... INTO OUTFILE` is the complement of `LOAD DATA INFILE`; the syntax for the `export_options` part of the statement consists of the same `FIELDS` and `LINES` clauses that are used with the `LOAD DATA INFILE` statement. See [Section 13.2.5, “LOAD DATA INFILE Syntax”](#).

`FIELDS ESCAPED BY` controls how to write special characters. If the `FIELDS ESCAPED BY` character is not empty, it is used as a prefix that precedes following characters on output:

- The `FIELDS ESCAPED BY` character
- The `FIELDS [OPTIONALLY] ENCLOSED BY` character
- The first character of the `FIELDS TERMINATED BY` and `LINES TERMINATED BY` values
- ASCII `NUL` (the zero-valued byte; what is actually written following the escape character is ASCII `'0'`, not a zero-valued byte)

The `FIELDS TERMINATED BY`, `ENCLOSED BY`, `ESCAPED BY`, or `LINES TERMINATED BY` characters *must* be escaped so that you can read the file back in reliably. ASCII `NUL` is escaped to make it easier to view with some paggers.

The resulting file does not have to conform to SQL syntax, so nothing else need be escaped.

If the `FIELDS ESCAPED BY` character is empty, no characters are escaped and `NULL` is output as `NULL`, not `\N`. It is probably not a good idea to specify an empty escape character, particularly if field values in your data contain any of the characters in the list just given.

Here is an example that produces a file in the comma-separated values (CSV) format used by many programs:

```
SELECT a,b,a+b INTO OUTFILE '/tmp/result.txt'
  FIELDS TERMINATED BY ',' OPTIONALLY ENCLOSED BY '"'
  LINES TERMINATED BY '\n'
FROM test_table;
```

- If you use `INTO DUMPFILE` instead of `INTO OUTFILE`, MySQL writes only one row into the file, without any column or line termination and without performing any escape processing. This is useful if you want to store a `BLOB` value in a file.
- The `INTO` clause can name a list of one or more user-defined variables. The selected values are assigned to the variables. The number of variables must match the number of columns.

Within a stored routine, the variables can be routine parameters or local variables. See [Section 18.2.7.3, “SELECT . . . INTO Statement”](#).

- **Note:** Any file created by `INTO OUTFILE` or `INTO DUMPFILE` is writable by all users on the server host. The reason for this is that the MySQL server cannot create a file that is owned by anyone other than the user under whose account it is running. (You should *never* run `mysqld` as `root` for this and other reasons.) The file thus must be world-writable so that you can manipulate its contents.
- The `SELECT` syntax description at the beginning this section shows the `INTO` clause near the end of the statement. It is also possible to use `INTO OUTFILE` or `INTO DUMPFILE` immediately preceding the `FROM` clause.
- A `PROCEDURE` clause names a procedure that should process the data in the result set. For an example, see [Section 26.4.1, “Procedure Analyse”](#).
- If you use `FOR UPDATE` with a storage engine that uses page or row locks, rows examined by the query are write-locked until the end of the current transaction. Using `LOCK IN SHARE MODE` sets a shared lock that allows other transactions to read the examined rows but not to update or delete them. See [Section 14.5.10.5, “SELECT . . . FOR UPDATE and SELECT . . . LOCK IN SHARE MODE Locking Reads”](#).

Following the `SELECT` keyword, you can use a number of options that affect the operation of the state-

ment.

The `ALL`, `DISTINCT`, and `DISTINCTROW` options specify whether duplicate rows should be returned. If none of these options are given, the default is `ALL` (all matching rows are returned). `DISTINCT` and `DISTINCTROW` are synonyms and specify removal of duplicate rows from the result set.

`HIGH_PRIORITY`, `STRAIGHT_JOIN`, and options beginning with `SQL_` are MySQL extensions to standard SQL.

- `HIGH_PRIORITY` gives the `SELECT` higher priority than a statement that updates a table. You should use this only for queries that are very fast and must be done at once. A `SELECT HIGH_PRIORITY` query that is issued while the table is locked for reading runs even if there is an update statement waiting for the table to be free.

`HIGH_PRIORITY` cannot be used with `SELECT` statements that are part of a `UNION`.

- `STRAIGHT_JOIN` forces the optimizer to join the tables in the order in which they are listed in the `FROM` clause. You can use this to speed up a query if the optimizer joins the tables in non-optimal order. See [Section 7.2.1, “Optimizing Queries with EXPLAIN”](#). `STRAIGHT_JOIN` also can be used in the `table_references` list. See [Section 13.2.7.1, “JOIN Syntax”](#).
- `SQL_BIG_RESULT` can be used with `GROUP BY` or `DISTINCT` to tell the optimizer that the result set has many rows. In this case, MySQL directly uses disk-based temporary tables if needed, and prefers sorting to using a temporary table with a key on the `GROUP BY` elements.
- `SQL_BUFFER_RESULT` forces the result to be put into a temporary table. This helps MySQL free the table locks early and helps in cases where it takes a long time to send the result set to the client.
- `SQL_SMALL_RESULT` can be used with `GROUP BY` or `DISTINCT` to tell the optimizer that the result set is small. In this case, MySQL uses fast temporary tables to store the resulting table instead of using sorting. This should not normally be needed.
- `SQL_CALC_FOUND_ROWS` tells MySQL to calculate how many rows there would be in the result set, disregarding any `LIMIT` clause. The number of rows can then be retrieved with `SELECT FOUND_ROWS()`. See [Section 12.10.3, “Information Functions”](#).
- `SQL_CACHE` tells MySQL to store the query result in the query cache if you are using a `query_cache_type` value of 2 or `DEMAND`. For a query that uses `UNION` or subqueries, this option effects any `SELECT` in the query. See [Section 5.14, “The MySQL Query Cache”](#).
- `SQL_NO_CACHE` tells MySQL not to store the query result in the query cache. See [Section 5.14, “The MySQL Query Cache”](#). For a query that uses `UNION` or subqueries, this option effects any `SELECT` in the query.

13.2.7.1. JOIN Syntax

MySQL supports the following `JOIN` syntaxes for the `table_references` part of `SELECT` statements and multiple-table `DELETE` and `UPDATE` statements:

```
table_references:
    table_reference [, table_reference] ...

table_reference:
    table_factor
  | join_table

table_factor:
    tbl_name [[AS] alias]
      [{USE|IGNORE|FORCE} INDEX (key_list)]
  | ( table_references )
  | { OJ table_reference LEFT OUTER JOIN table_reference
```

```

        ON conditional_expr }

join_table:
  table_reference [INNER | CROSS] JOIN table_factor [join_condition]
  | table_reference STRAIGHT_JOIN table_factor
  | table_reference STRAIGHT_JOIN table_factor ON condition
  | table_reference LEFT [OUTER] JOIN table_factor join_condition
  | table_reference NATURAL [LEFT [OUTER]] JOIN table_factor
  | table_reference RIGHT [OUTER] JOIN table_factor join_condition
  | table_reference NATURAL [RIGHT [OUTER]] JOIN table_factor

join_condition:
  ON conditional_expr
  | USING (column_list)

```

A table reference is also known as a join expression.

The syntax of *table_factor* is extended in comparison with the SQL Standard. The latter accepts only *table_reference*, not a list of them inside a pair of parentheses.

This is a conservative extension if we consider each comma in a list of *table_reference* items as equivalent to an inner join. For example:

```

SELECT * FROM t1 LEFT JOIN (t2, t3, t4)
        ON (t2.a=t1.a AND t3.b=t1.b AND t4.c=t1.c)

```

is equivalent to:

```

SELECT * FROM t1 LEFT JOIN (t2 CROSS JOIN t3 CROSS JOIN t4)
        ON (t2.a=t1.a AND t3.b=t1.b AND t4.c=t1.c)

```

In MySQL, **CROSS JOIN** is a syntactic equivalent to **INNER JOIN** (they can replace each other). In standard SQL, they are not equivalent. **INNER JOIN** is used with an **ON** clause, **CROSS JOIN** is used otherwise.

In general, parentheses can be ignored in join expressions containing only inner join operations. MySQL also supports nested joins (see [Section 7.2.10, “Nested Join Optimization”](#)).

The following list describes general factors to take into account when writing joins.

- A table reference can be aliased using *tbl_name AS alias_name* or *tbl_name alias_name*:

```

SELECT t1.name, t2.salary
FROM employee AS t1 INNER JOIN info AS t2 ON t1.name = t2.name;

SELECT t1.name, t2.salary
FROM employee t1 INNER JOIN info t2 ON t1.name = t2.name;

```

- **INNER JOIN** and **,** (comma) are semantically equivalent in the absence of a join condition: both produce a Cartesian product between the specified tables (that is, each and every row in the first table is joined to each and every row in the second table).

However, the precedence of the comma operator is less than that of **INNER JOIN**, **CROSS JOIN**, **LEFT JOIN**, and so on. If you mix comma joins with the other join types when there is a join condition, an error of the form **Unknown column 'col_name' in 'on clause'** may occur. Information about dealing with this problem is given later in this section.

- The **ON** conditional is any conditional expression of the form that can be used in a **WHERE** clause. Generally, you should use the **ON** clause for conditions that specify how to join tables, and the **WHERE** clause to restrict which rows you want in the result set.

- If there is no matching row for the right table in the `ON` or `USING` part in a `LEFT JOIN`, a row with all columns set to `NULL` is used for the right table. You can use this fact to find rows in a table that have no counterpart in another table:

```
SELECT table1.* FROM table1
LEFT JOIN table2 ON table1.id=table2.id
WHERE table2.id IS NULL;
```

This example finds all rows in `table1` with an `id` value that is not present in `table2` (that is, all rows in `table1` with no corresponding row in `table2`). This assumes that `table2.id` is declared `NOT NULL`. See [Section 7.2.9, “LEFT JOIN and RIGHT JOIN Optimization”](#).

- The `USING(column_list)` clause names a list of columns that must exist in both tables. If tables `a` and `b` both contain columns `c1`, `c2`, and `c3`, the following join compares corresponding columns from the two tables:

```
a LEFT JOIN b USING (c1,c2,c3)
```

- The `NATURAL [LEFT] JOIN` of two tables is defined to be semantically equivalent to an `INNER JOIN` or a `LEFT JOIN` with a `USING` clause that names all columns that exist in both tables.
- `RIGHT JOIN` works analogously to `LEFT JOIN`. To keep code portable across databases, it is recommended that you use `LEFT JOIN` instead of `RIGHT JOIN`.
- The `{ OJ ... LEFT OUTER JOIN ... }` syntax shown in the join syntax description exists only for compatibility with ODBC. The curly braces in the syntax should be written literally; they are not metasyntax as used elsewhere in syntax descriptions.
- `STRAIGHT_JOIN` is identical to `JOIN`, except that the left table is always read before the right table. This can be used for those (few) cases for which the join optimizer puts the tables in the wrong order.

Some join examples:

```
SELECT * FROM table1, table2;
SELECT * FROM table1 INNER JOIN table2 ON table1.id=table2.id;
SELECT * FROM table1 LEFT JOIN table2 ON table1.id=table2.id;
SELECT * FROM table1 LEFT JOIN table2 USING (id);
SELECT * FROM table1 LEFT JOIN table2 ON table1.id=table2.id
LEFT JOIN table3 ON table2.id=table3.id;
```

You can provide hints as to which index MySQL should use when retrieving information from a table. By specifying `USE INDEX (key_list)`, you can tell MySQL to use only one of the possible indexes to find rows in the table. The alternative syntax `IGNORE INDEX (key_list)` can be used to tell MySQL to not use some particular index. These hints are useful if `EXPLAIN` shows that MySQL is using the wrong index from the list of possible indexes.

You can also use `FORCE INDEX`, which acts like `USE INDEX (key_list)` but with the addition that a table scan is assumed to be *very* expensive. In other words, a table scan is used only if there is no way to use one of the given indexes to find rows in the table.

`USE INDEX`, `IGNORE INDEX`, and `FORCE INDEX` affect only which indexes are used when MySQL decides how to find rows in the table and how to do the join. They do not affect whether an index is used when resolving an `ORDER BY` or `GROUP BY`.

`USE KEY`, `IGNORE KEY`, and `FORCE KEY` are synonyms for `USE INDEX`, `IGNORE INDEX`, and

FORCE INDEX.

Examples:

```
SELECT * FROM table1 USE INDEX (key1,key2)
  WHERE key1=1 AND key2=2 AND key3=3;

SELECT * FROM table1 IGNORE INDEX (key3)
  WHERE key1=1 AND key2=2 AND key3=3;
```

Join Processing Changes in MySQL 5.0.12

Note: Natural joins and joins with **USING**, including outer join variants, are processed according to the SQL:2003 standard. The goal was to align the syntax and semantics of MySQL with respect to **NATURAL JOIN** and **JOIN ... USING** according to SQL:2003. However, these changes in join processing can result in different output columns for some joins. Also, some queries that appeared to work correctly in older versions (prior to 5.0.12) must be rewritten to comply with the standard.

These changes have five main aspects:

- The way that MySQL determines the result columns of **NATURAL** or **USING** join operations (and thus the result of the entire **FROM** clause).
- Expansion of **SELECT *** and **SELECT tbl_name.*** into a list of selected columns.
- Resolution of column names in **NATURAL** or **USING** joins.
- Transformation of **NATURAL** or **USING** joins into **JOIN ... ON**.
- Resolution of column names in the **ON** condition of a **JOIN ... ON**.

The following list provides more detail about several effects of current join processing versus join processing in older versions. The term “previously” means “prior to MySQL 5.0.12.”

- The columns of a **NATURAL** join or a **USING** join may be different from previously. Specifically, redundant output columns no longer appear, and the order of columns for **SELECT *** expansion may be different from before.

Consider this set of statements:

```
CREATE TABLE t1 (i INT, j INT);
CREATE TABLE t2 (k INT, j INT);
INSERT INTO t1 VALUES(1,1);
INSERT INTO t2 VALUES(1,1);
SELECT * FROM t1 NATURAL JOIN t2;
SELECT * FROM t1 JOIN t2 USING (j);
```

Previously, the statements produced this output:

```
+-----+-----+-----+-----+
| i     | j     | k     | j     |
+-----+-----+-----+-----+
| 1     | 1     | 1     | 1     |
+-----+-----+-----+-----+
| i     | j     | k     | j     |
+-----+-----+-----+-----+
| 1     | 1     | 1     | 1     |
+-----+-----+-----+-----+
```

In the first **SELECT** statement, column **j** appears in both tables and thus becomes a join column, so,

according to standard SQL, it should appear only once in the output, not twice. Similarly, in the second `SELECT` statement, column `j` is named in the `USING` clause and should appear only once in the output, not twice. But in both cases, the redundant column is not eliminated. Also, the order of the columns is not correct according to standard SQL.

Now the statements produce this output:

```
+-----+-----+-----+
| j     | i     | k     |
+-----+-----+-----+
| 1     | 1     | 1     |
+-----+-----+-----+
| j     | i     | k     |
+-----+-----+-----+
| 1     | 1     | 1     |
+-----+-----+-----+
```

The redundant column is eliminated and the column order is correct according to standard SQL:

- First, coalesced common columns of the two joined tables, in the order in which they occur in the first table
- Second, columns unique to the first table, in order in which they occur in that table
- Third, columns unique to the second table, in order in which they occur in that table

The single result column that replaces two common columns is defined via the coalesce operation. That is, from two `t1.a` and `t2.a` the resulting single join column `a` is defined as `a = COALESCE(t1.a, t2.a)`, where:

```
COALESCE(x, y) = (CASE WHEN V1 IS NOT NULL THEN V1 ELSE V2 END)
```

If the join operation is any other join, the result columns of the join consists of the concatenation of all columns of the joined tables. This is the same as previously.

A consequence of the definition of coalesced columns is that, for outer joins, the coalesced column contains the value of the non-`NULL` column if one of the two columns is always `NULL`. If neither or both columns are `NULL`, both common columns have the same value, so it doesn't matter which one is chosen as the value of the coalesced column. A simple way to interpret this is to consider that a coalesced column of an outer join is represented by the common column of the inner table of a `JOIN`. Suppose that the tables `t1(a,b)` and `t2(a,c)` have the following contents:

```
t1    t2
----  ----
1 x   2 z
2 y   3 w
```

Then:

```
mysql> SELECT * FROM t1 NATURAL LEFT JOIN t2;
```

```
+-----+-----+-----+
| a     | b     | c     |
+-----+-----+-----+
| 1     | x     | NULL  |
| 2     | y     | z     |
+-----+-----+-----+
```

Here column `a` contains the values of `t1.a`.

```
mysql> SELECT * FROM t1 NATURAL RIGHT JOIN t2;
```

```
+-----+-----+-----+
| a     | c     | b     |
+-----+-----+-----+
```

2	z	y
3	w	NULL

Here column `a` contains the values of `t2.a`.

Compare these results to the otherwise equivalent queries with `JOIN ... ON`:

```
mysql> SELECT * FROM t1 LEFT JOIN t2 ON (t1.a = t2.a);
```

a	b	a	c
1	x	NULL	NULL
2	y	2	z

```
mysql> SELECT * FROM t1 RIGHT JOIN t2 ON (t1.a = t2.a);
```

a	b	a	c
2	y	2	z
NULL	NULL	3	w

- Previously, a `USING` clause could be rewritten as an `ON` clause that compares corresponding columns. For example, the following two clauses were semantically identical:

```
a LEFT JOIN b USING (c1,c2,c3)
a LEFT JOIN b ON a.c1=b.c1 AND a.c2=b.c2 AND a.c3=b.c3
```

Now the two clauses no longer are quite the same:

- With respect to determining which rows satisfy the join condition, both joins remain semantically identical.
- With respect to determining which columns to display for `SELECT *` expansion, the two joins are not semantically identical. The `USING` join selects the coalesced value of corresponding columns, whereas the `ON` join selects all columns from all tables. For the preceding `USING` join, `SELECT *` selects these values:

```
COALESCE(a.c1,b.c1), COALESCE(a.c2,b.c2), COALESCE(a.c3,b.c3)
```

For the `ON` join, `SELECT *` selects these values:

```
a.c1, a.c2, a.c3, b.c1, b.c2, b.c3
```

With an inner join, `COALESCE(a.c1,b.c1)` is the same as either `a.c1` or `b.c1` because both columns will have the same value. With an outer join (such as `LEFT JOIN`), one of the two columns can be `NULL`. That column will be omitted from the result.

- The evaluation of multi-way natural joins differs in a very important way that affects the result of `NATURAL` or `USING` joins and that can require query rewriting. Suppose that you have three tables `t1(a,b)`, `t2(c,b)`, and `t3(a,c)` that each have one row: `t1(1,2)`, `t2(10,2)`, and `t3(7,10)`. Suppose also that you have this `NATURAL JOIN` on the three tables:

```
SELECT ... FROM t1 NATURAL JOIN t2 NATURAL JOIN t3;
```

Previously, the left operand of the second join was considered to be `t2`, whereas it should be the nested join (`t1 NATURAL JOIN t2`). As a result, the columns of `t3` are checked for common

columns only in `t2`, and, if `t3` has common columns with `t1`, these columns are not used as equi-join columns. Thus, previously, the preceding query was transformed to the following equi-join:

```
SELECT ... FROM t1, t2, t3
WHERE t1.b = t2.b AND t2.c = t3.c;
```

That join is missing one more equi-join predicate (`t1.a = t3.a`). As a result, it produces one row, not the empty result that it should. The correct equivalent query is this:

```
SELECT ... FROM t1, t2, t3
WHERE t1.b = t2.b AND t2.c = t3.c AND t1.a = t3.a;
```

If you require the same query result in current versions of MySQL as in older versions, rewrite the natural join as the first equi-join.

- Previously, the comma operator (`,`) and `JOIN` both had the same precedence, so the join expression `t1, t2 JOIN t3` was interpreted as `((t1, t2) JOIN t3)`. Now `JOIN` has higher precedence, so the expression is interpreted as `(t1, (t2 JOIN t3))`. This change affects statements that use an `ON` clause, because that clause can refer only to columns in the operands of the join, and the change in precedence changes interpretation of what those operands are.

Example:

```
CREATE TABLE t1 (i1 INT, j1 INT);
CREATE TABLE t2 (i2 INT, j2 INT);
CREATE TABLE t3 (i3 INT, j3 INT);
INSERT INTO t1 VALUES(1,1);
INSERT INTO t2 VALUES(1,1);
INSERT INTO t3 VALUES(1,1);
SELECT * FROM t1, t2 JOIN t3 ON (t1.i1 = t3.i3);
```

Previously, the `SELECT` was legal due to the implicit grouping of `t1, t2` as `(t1, t2)`. Now the `JOIN` takes precedence, so the operands for the `ON` clause are `t2` and `t3`. Because `t1.i1` is not a column in either of the operands, the result is an `Unknown column 't1.i1' in 'on clause'` error. To allow the join to be processed, group the first two tables explicitly with parentheses so that the operands for the `ON` clause are `(t1, t2)` and `t3`:

```
SELECT * FROM (t1, t2) JOIN t3 ON (t1.i1 = t3.i3);
```

Alternatively, avoid the use of the comma operator and use `JOIN` instead:

```
SELECT * FROM t1 JOIN t2 JOIN t3 ON (t1.i1 = t3.i3);
```

This change also applies to statements that mix the comma operator with `INNER JOIN`, `CROSS JOIN`, `LEFT JOIN`, and `RIGHT JOIN`, all of which now have higher precedence than the comma operator.

- Previously, the `ON` clause could refer to columns in tables named to its right. Now an `ON` clause can refer only to its operands.

Example:

```
CREATE TABLE t1 (i1 INT);
CREATE TABLE t2 (i2 INT);
CREATE TABLE t3 (i3 INT);
SELECT * FROM t1 JOIN t2 ON (i1 = i3) JOIN t3;
```

Previously, the `SELECT` statement was legal. Now the statement fails with an `Unknown column 'i3' in 'on clause'` error because `i3` is a column in `t3`, which is not an operand of the `ON`

clause. The statement should be rewritten as follows:

```
SELECT * FROM t1 JOIN t2 JOIN t3 ON (i1 = i3);
```

- Resolution of column names in **NATURAL** or **USING** joins is different than previously. For column names that are outside the **FROM** clause, MySQL now handles a superset of the queries compared to previously. That is, in cases when MySQL formerly issued an error that some column is ambiguous, the query now is handled correctly. This is due to the fact that MySQL now treats the common columns of **NATURAL** or **USING** joins as a single column, so when a query refers to such columns, the query compiler does not consider them as ambiguous.

Example:

```
SELECT * FROM t1 NATURAL JOIN t2 WHERE b > 1;
```

Previously, this query would produce an error **ERROR 1052 (23000): Column 'b' in where clause is ambiguous**. Now the query produces the correct result:

b	c	y
4	2	3

One extension of MySQL compared to the SQL:2003 standard is that MySQL allows you to qualify the common (coalesced) columns of **NATURAL** or **USING** joins (just as previously), while the standard disallows that.

13.2.7.2. UNION Syntax

```
SELECT ...
UNION [ALL | DISTINCT] SELECT ...
[UNION [ALL | DISTINCT] SELECT ...]
```

UNION is used to combine the result from multiple **SELECT** statements into a single result set.

The column names from the first **SELECT** statement are used as the column names for the results returned. Selected columns listed in corresponding positions of each **SELECT** statement should have the same data type. (For example, the first column selected by the first statement should have the same type as the first column selected by the other statements.)

If the data types of corresponding **SELECT** columns do not match, the types and lengths of the columns in the **UNION** result take into account the values retrieved by all of the **SELECT** statements. For example, consider the following:

```
mysql> SELECT REPEAT('a',1) UNION SELECT REPEAT('b',10);
+-----+
| REPEAT('a',1) |
+-----+
| a             |
| bbbbbbbbbb   |
+-----+
```

(In some earlier versions of MySQL, only the type and length from the first **SELECT** would have been used and the second row would have been truncated to a length of 1.)

The **SELECT** statements are normal select statements, but with the following restrictions:

- Only the last `SELECT` statement can use `INTO OUTFILE`.
- `HIGH_PRIORITY` cannot be used with `SELECT` statements that are part of a `UNION`. If you specify it for the first `SELECT`, it has no effect. If you specify it for any subsequent `SELECT` statements, a syntax error results.

The default behavior for `UNION` is that duplicate rows are removed from the result. The optional `DISTINCT` keyword has no effect other than the default because it also specifies duplicate-row removal. With the optional `ALL` keyword, duplicate-row removal does not occur and the result includes all matching rows from all the `SELECT` statements.

You can mix `UNION ALL` and `UNION DISTINCT` in the same query. Mixed `UNION` types are treated such that a `DISTINCT` union overrides any `ALL` union to its left. A `DISTINCT` union can be produced explicitly by using `UNION DISTINCT` or implicitly by using `UNION` with no following `DISTINCT` or `ALL` keyword.

To use an `ORDER BY` or `LIMIT` clause to sort or limit the entire `UNION` result, parenthesize the individual `SELECT` statements and place the `ORDER BY` or `LIMIT` after the last one. The following example uses both clauses:

```
(SELECT a FROM t1 WHERE a=10 AND B=1)
UNION
(SELECT a FROM t2 WHERE a=11 AND B=2)
ORDER BY a LIMIT 10;
```

This kind of `ORDER BY` cannot use column references that include a table name (that is, names in `tbl_name.col_name` format). Instead, provide a column alias in the first `SELECT` statement and refer to the alias in the `ORDER BY`. (Alternatively, refer to the column in the `ORDER BY` using its column position. However, use of column positions is deprecated.)

Also, if a column to be sorted is aliased, the `ORDER BY` clause *must* refer to the alias, not the column name. The first of the following statements will work, but the second will fail with an `Unknown column 'a' in 'order clause'` error:

```
(SELECT a AS b FROM t) UNION (SELECT ...) ORDER BY b;
(SELECT a AS b FROM t) UNION (SELECT ...) ORDER BY a;
```

To apply `ORDER BY` or `LIMIT` to an individual `SELECT`, place the clause inside the parentheses that enclose the `SELECT`:

```
(SELECT a FROM t1 WHERE a=10 AND B=1 ORDER BY a LIMIT 10)
UNION
(SELECT a FROM t2 WHERE a=11 AND B=2 ORDER BY a LIMIT 10);
```

Use of `ORDER BY` for individual `SELECT` statements implies nothing about the order in which the rows appear in the final result because `UNION` by default produces an unordered set of rows. If `ORDER BY` appears with `LIMIT`, it is used to determine the subset of the selected rows to retrieve for the `SELECT`, but does not necessarily affect the order of those rows in the final `UNION` result. If `ORDER BY` appears without `LIMIT` in a `SELECT`, it is optimized away because it will have no effect anyway.

To cause rows in a `UNION` result to consist of the sets of rows retrieved by each `SELECT` one after the other, select an additional column in each `SELECT` to use as a sort column and add an `ORDER BY` following the last `SELECT`:

```
(SELECT 1 AS sort_col, col1a, col1b, ... FROM t1)
UNION
(SELECT 2, col2a, col2b, ... FROM t2) ORDER BY sort_col;
```

To additionally maintain sort order within individual `SELECT` results, add a secondary column to the `ORDER BY` clause:

```
(SELECT 1 AS sort_col, col1a, col1b, ... FROM t1)
UNION
(SELECT 2, col2a, col2b, ... FROM t2) ORDER BY sort_col, col1a;
```

13.2.8. Subquery Syntax

A subquery is a `SELECT` statement within another statement.

Starting with MySQL 4.1, all subquery forms and operations that the SQL standard requires are supported, as well as a few features that are MySQL-specific.

Here is an example of a subquery:

```
SELECT * FROM t1 WHERE column1 = (SELECT column1 FROM t2);
```

In this example, `SELECT * FROM t1 ...` is the *outer query* (or *outer statement*), and `(SELECT column1 FROM t2)` is the *subquery*. We say that the subquery is *nested* within the outer query, and in fact it is possible to nest subqueries within other subqueries, to a considerable depth. A subquery must always appear within parentheses.

The main advantages of subqueries are:

- They allow queries that are *structured* so that it is possible to isolate each part of a statement.
- They provide alternative ways to perform operations that would otherwise require complex joins and unions.
- They are, in many people's opinion, readable. Indeed, it was the innovation of subqueries that gave people the original idea of calling the early SQL “Structured Query Language.”

Here is an example statement that shows the major points about subquery syntax as specified by the SQL standard and supported in MySQL:

```
DELETE FROM t1
WHERE s11 > ANY
(SELECT COUNT(*) /* no hint */ FROM t2
WHERE NOT EXISTS
(SELECT * FROM t3
WHERE ROW(5*t2.s1,77)=
(SELECT 50,11*s1 FROM t4 UNION SELECT 50,77 FROM
(SELECT * FROM t5) AS t5));
```

A subquery can return a scalar (a single value), a single row, a single column, or a table (one or more rows of one or more columns). These are called scalar, column, row, and table subqueries. Subqueries that return a particular kind of result often can be used only in certain contexts, as described in the following sections.

There are few restrictions on the type of statements in which subqueries can be used. A subquery can contain any of the keywords or clauses that an ordinary `SELECT` can contain: `DISTINCT`, `GROUP BY`, `ORDER BY`, `LIMIT`, joins, index hints, `UNION` constructs, comments, functions, and so on.

One restriction is that a subquery's outer statement must be one of: `SELECT`, `INSERT`, `UPDATE`, `DELETE`, `SET`, or `DO`. Another restriction is that currently you cannot modify a table and select from the same table in a subquery. This applies to statements such as `DELETE`, `INSERT`, `REPLACE`, `UPDATE`, and (because subqueries can be used in the `SET` clause) `LOAD DATA INFILE`.

A more comprehensive discussion of restrictions on subquery use, including performance issues for certain forms of subquery syntax, is given in [Section I.3, “Restrictions on Subqueries”](#).

13.2.8.1. The Subquery as Scalar Operand

In its simplest form, a subquery is a scalar subquery that returns a single value. A scalar subquery is a simple operand, and you can use it almost anywhere a single column value or literal is legal, and you can expect it to have those characteristics that all operands have: a data type, a length, an indication whether it can be `NULL`, and so on. For example:

```
CREATE TABLE t1 (s1 INT, s2 CHAR(5) NOT NULL);
INSERT INTO t1 VALUES(100, 'abcde');
SELECT (SELECT s2 FROM t1);
```

The subquery in this `SELECT` returns a single value ('abcde') that has a data type of `CHAR`, a length of 5, a character set and collation equal to the defaults in effect at `CREATE TABLE` time, and an indication that the value in the column can be `NULL`. In fact, almost all subqueries can be `NULL`. If the table used in the example were empty, the value of the subquery would be `NULL`.

There are a few contexts in which a scalar subquery cannot be used. If a statement allows only a literal value, you cannot use a subquery. For example, `LIMIT` requires literal integer arguments, and `LOAD DATA INFILE` requires a literal string filename. You cannot use subqueries to supply these values.

When you see examples in the following sections that contain the rather spartan construct (`SELECT column1 FROM t1`), imagine that your own code contains much more diverse and complex constructions.

Suppose that we make two tables:

```
CREATE TABLE t1 (s1 INT);
INSERT INTO t1 VALUES (1);
CREATE TABLE t2 (s1 INT);
INSERT INTO t2 VALUES (2);
```

Then perform a `SELECT`:

```
SELECT (SELECT s1 FROM t2) FROM t1;
```

The result is 2 because there is a row in `t2` containing a column `s1` that has a value of 2.

A scalar subquery can be part of an expression, but remember the parentheses, even if the subquery is an operand that provides an argument for a function. For example:

```
SELECT UPPER((SELECT s1 FROM t1)) FROM t2;
```

13.2.8.2. Comparisons Using Subqueries

The most common use of a subquery is in the form:

```
non_subquery_operand comparison_operator (subquery)
```

Where *comparison_operator* is one of these operators:

```
= > < >= <= <>
```

For example:

```
... 'a' = (SELECT column1 FROM t1)
```

At one time the only legal place for a subquery was on the right side of a comparison, and you might still find some old DBMSs that insist on this.

Here is an example of a common-form subquery comparison that you cannot do with a join. It finds all the values in table `t1` that are equal to a maximum value in table `t2`:

```
SELECT column1 FROM t1
WHERE column1 = (SELECT MAX(column2) FROM t2);
```

Here is another example, which again is impossible with a join because it involves aggregating for one of the tables. It finds all rows in table `t1` containing a value that occurs twice in a given column:

```
SELECT * FROM t1 AS t
WHERE 2 = (SELECT COUNT(*) FROM t1 WHERE t1.id = t.id);
```

For a comparison performed with one of these operators, the subquery must return a scalar, with the exception that `=` can be used with row subqueries. See [Section 13.2.8.5, “Row Subqueries”](#).

13.2.8.3. Subqueries with **ANY**, **IN**, and **SOME**

Syntax:

```
operand comparison_operator ANY (subquery)
operand IN (subquery)
operand comparison_operator SOME (subquery)
```

The **ANY** keyword, which must follow a comparison operator, means “return **TRUE** if the comparison is **TRUE** for **ANY** of the values in the column that the subquery returns.” For example:

```
SELECT s1 FROM t1 WHERE s1 > ANY (SELECT s1 FROM t2);
```

Suppose that there is a row in table `t1` containing `(10)`. The expression is **TRUE** if table `t2` contains `(21, 14, 7)` because there is a value `7` in `t2` that is less than `10`. The expression is **FALSE** if table `t2` contains `(20, 10)`, or if table `t2` is empty. The expression is **UNKNOWN** if table `t2` contains `(NULL, NULL, NULL)`.

The word **IN** is an alias for `= ANY`. Thus, these two statements are the same:

```
SELECT s1 FROM t1 WHERE s1 = ANY (SELECT s1 FROM t2);
SELECT s1 FROM t1 WHERE s1 IN (SELECT s1 FROM t2);
```

However, **NOT IN** is not an alias for `<> ANY`, but for `<> ALL`. See [Section 13.2.8.4, “Subqueries with ALL”](#).

The word **SOME** is an alias for **ANY**. Thus, these two statements are the same:

```
SELECT s1 FROM t1 WHERE s1 <> ANY (SELECT s1 FROM t2);
SELECT s1 FROM t1 WHERE s1 <> SOME (SELECT s1 FROM t2);
```

Use of the word **SOME** is rare, but this example shows why it might be useful. To most people's ears, the English phrase “a is not equal to any b” means “there is no b which is equal to a,” but that is not what is meant by the SQL syntax. The syntax means “there is some b to which a is not equal.” Using `<> SOME` instead helps ensure that everyone understands the true meaning of the query.

13.2.8.4. Subqueries with **ALL**

Syntax:

```
operand comparison_operator ALL (subquery)
```

The word **ALL**, which must follow a comparison operator, means “return **TRUE** if the comparison is **TRUE** for **ALL** of the values in the column that the subquery returns.” For example:

```
SELECT s1 FROM t1 WHERE s1 > ALL (SELECT s1 FROM t2);
```

Suppose that there is a row in table **t1** containing (10). The expression is **TRUE** if table **t2** contains (-5, 0, +5) because 10 is greater than all three values in **t2**. The expression is **FALSE** if table **t2** contains (12, 6, NULL, -100) because there is a single value 12 in table **t2** that is greater than 10. The expression is *unknown* (that is, **NULL**) if table **t2** contains (0, NULL, 1).

Finally, if table **t2** is empty, the result is **TRUE**. So, the following statement is **TRUE** when table **t2** is empty:

```
SELECT * FROM t1 WHERE 1 > ALL (SELECT s1 FROM t2);
```

But this statement is **NULL** when table **t2** is empty:

```
SELECT * FROM t1 WHERE 1 > (SELECT s1 FROM t2);
```

In addition, the following statement is **NULL** when table **t2** is empty:

```
SELECT * FROM t1 WHERE 1 > ALL (SELECT MAX(s1) FROM t2);
```

In general, *tables containing NULL values* and *empty tables* are “edge cases.” When writing subquery code, always consider whether you have taken those two possibilities into account.

NOT IN is an alias for **<> ALL**. Thus, these two statements are the same:

```
SELECT s1 FROM t1 WHERE s1 <> ALL (SELECT s1 FROM t2);
SELECT s1 FROM t1 WHERE s1 NOT IN (SELECT s1 FROM t2);
```

13.2.8.5. Row Subqueries

The discussion to this point has been of scalar or column subqueries; that is, subqueries that return a single value or a column of values. A *row subquery* is a subquery variant that returns a single row and can thus return more than one column value. Here are two examples:

```
SELECT * FROM t1 WHERE (1,2) = (SELECT column1, column2 FROM t2);
SELECT * FROM t1 WHERE ROW(1,2) = (SELECT column1, column2 FROM t2);
```

The queries here are both **TRUE** if table **t2** has a row where **column1 = 1** and **column2 = 2**.

The expressions (1, 2) and **ROW(1, 2)** are sometimes called *row constructors*. The two are equivalent. They are legal in other contexts as well. For example, the following two statements are semantically equivalent (although the first one cannot be optimized until MySQL 5.1.12):

```
SELECT * FROM t1 WHERE (column1, column2) = (1, 1);
SELECT * FROM t1 WHERE column1 = 1 AND column2 = 1;
```

The normal use of row constructors is for comparisons with subqueries that return two or more columns. For example, the following query answers the request, “find all rows in table **t1** that also exist in table **t2**”:

```
SELECT column1, column2, column3
FROM t1
WHERE (column1, column2, column3) IN
(SELECT column1, column2, column3 FROM t2);
```

13.2.8.6. EXISTS and NOT EXISTS

If a subquery returns any rows at all, `EXISTS subquery` is `TRUE`, and `NOT EXISTS subquery` is `FALSE`. For example:

```
SELECT column1 FROM t1 WHERE EXISTS (SELECT * FROM t2);
```

Traditionally, an `EXISTS` subquery starts with `SELECT *`, but it could begin with `SELECT 5` or `SELECT column1` or anything at all. MySQL ignores the `SELECT` list in such a subquery, so it makes no difference.

For the preceding example, if `t2` contains any rows, even rows with nothing but `NULL` values, the `EXISTS` condition is `TRUE`. This is actually an unlikely example because a `[NOT] EXISTS` subquery almost always contains correlations. Here are some more realistic examples:

- What kind of store is present in one or more cities?

```
SELECT DISTINCT store_type FROM stores
WHERE EXISTS (SELECT * FROM cities_stores
              WHERE cities_stores.store_type = stores.store_type);
```

- What kind of store is present in no cities?

```
SELECT DISTINCT store_type FROM stores
WHERE NOT EXISTS (SELECT * FROM cities_stores
                  WHERE cities_stores.store_type = stores.store_type);
```

- What kind of store is present in all cities?

```
SELECT DISTINCT store_type FROM stores s1
WHERE NOT EXISTS (
  SELECT * FROM cities WHERE NOT EXISTS (
    SELECT * FROM cities_stores
    WHERE cities_stores.city = cities.city
    AND cities_stores.store_type = stores.store_type));
```

The last example is a double-nested `NOT EXISTS` query. That is, it has a `NOT EXISTS` clause within a `NOT EXISTS` clause. Formally, it answers the question “does a city exist with a store that is not in `Stores`”? But it is easier to say that a nested `NOT EXISTS` answers the question “is `x TRUE` for all `y`?”

13.2.8.7. Correlated Subqueries

A *correlated subquery* is a subquery that contains a reference to a table that also appears in the outer query. For example:

```
SELECT * FROM t1 WHERE column1 = ANY
(SELECT column1 FROM t2 WHERE t2.column2 = t1.column2);
```

Notice that the subquery contains a reference to a column of `t1`, even though the subquery's `FROM` clause does not mention a table `t1`. So, MySQL looks outside the subquery, and finds `t1` in the outer query.

Suppose that table `t1` contains a row where `column1 = 5` and `column2 = 6`; meanwhile, table `t2` contains a row where `column1 = 5` and `column2 = 7`. The simple expression `... WHERE column1 = ANY (SELECT column1 FROM t2)` would be `TRUE`, but in this example, the `WHERE` clause within the subquery is `FALSE` (because `(5,6)` is not equal to `(5,7)`), so the subquery as a whole is `FALSE`.

Scoping rule: MySQL evaluates from inside to outside. For example:

```
SELECT column1 FROM t1 AS x
WHERE x.column1 = (SELECT column1 FROM t2 AS x
WHERE x.column1 = (SELECT column1 FROM t3
WHERE x.column2 = t3.column1));
```

In this statement, `x.column2` must be a column in table `t2` because `SELECT column1 FROM t2 AS x ...` renames `t2`. It is not a column in table `t1` because `SELECT column1 FROM t1 ...` is an outer query that is *farther out*.

For subqueries in `HAVING` or `ORDER BY` clauses, MySQL also looks for column names in the outer select list.

For certain cases, a correlated subquery is optimized. For example:

```
val IN (SELECT key_val FROM tbl_name WHERE correlated_condition)
```

Otherwise, they are inefficient and likely to be slow. Rewriting the query as a join might improve performance.

Correlated subqueries cannot refer to the results of aggregate functions from the outer query.

13.2.8.8. Subqueries in the `FROM` clause

Subqueries are legal in a `SELECT` statement's `FROM` clause. The actual syntax is:

```
SELECT ... FROM (subquery) [AS] name ...
```

The `[AS] name` clause is mandatory, because every table in a `FROM` clause must have a name. Any columns in the `subquery` select list must have unique names. You can find this syntax described elsewhere in this manual, where the term used is “derived tables.”

For the sake of illustration, assume that you have this table:

```
CREATE TABLE t1 (s1 INT, s2 CHAR(5), s3 FLOAT);
```

Here is how to use a subquery in the `FROM` clause, using the example table:

```
INSERT INTO t1 VALUES (1, '1', 1.0);
INSERT INTO t1 VALUES (2, '2', 2.0);
SELECT sb1, sb2, sb3
FROM (SELECT s1 AS sb1, s2 AS sb2, s3*2 AS sb3 FROM t1) AS sb
WHERE sb1 > 1;
```

Result: `2, '2', 4.0`.

Here is another example: Suppose that you want to know the average of a set of sums for a grouped table. This does not work:

```
SELECT AVG(SUM(column1)) FROM t1 GROUP BY column1;
```

However, this query provides the desired information:

```
SELECT AVG(sum_column1)
FROM (SELECT SUM(column1) AS sum_column1
FROM t1 GROUP BY column1) AS t1;
```

Notice that the column name used within the subquery (`sum_column1`) is recognized in the outer query.

Subqueries in the `FROM` clause can return a scalar, column, row, or table. Subqueries in the `FROM` clause cannot be correlated subqueries.

Subqueries in the `FROM` clause are executed even for the `EXPLAIN` statement (that is, derived temporary tables are built). This occurs because upper level queries need information about all tables during optimization phase.

13.2.8.9. Subquery Errors

There are some errors that apply only to subqueries. This section describes them.

- Unsupported subquery syntax:

```
ERROR 1235 (ER_NOT_SUPPORTED_YET)
SQLSTATE = 42000
Message = "This version of MySQL does not yet support
'LIMIT & IN/ALL/ANY/SOME subquery' "
```

This means that statements of the following form do not work yet:

```
SELECT * FROM t1 WHERE s1 IN (SELECT s2 FROM t2 ORDER BY s1 LIMIT 1)
```

- Incorrect number of columns from subquery:

```
ERROR 1241 (ER_OPERAND_COL)
SQLSTATE = 21000
Message = "Operand should contain 1 column(s) "
```

This error occurs in cases like this:

```
SELECT (SELECT column1, column2 FROM t2) FROM t1;
```

You may use a subquery that returns multiple columns, if the purpose is comparison. See [Section 13.2.8.5, “Row Subqueries”](#). However, in other contexts, the subquery must be a scalar operand.

- Incorrect number of rows from subquery:

```
ERROR 1242 (ER_SUBSELECT_NO_1_ROW)
SQLSTATE = 21000
Message = "Subquery returns more than 1 row"
```

This error occurs for statements where the subquery returns more than one row. Consider the following example:

```
SELECT * FROM t1 WHERE column1 = (SELECT column1 FROM t2);
```

If `SELECT column1 FROM t2` returns just one row, the previous query will work. If the subquery returns more than one row, error 1242 will occur. In that case, the query should be rewritten

as:

```
SELECT * FROM t1 WHERE column1 = ANY (SELECT column1 FROM t2);
```

- Incorrectly used table in subquery:

```
Error 1093 (ER_UPDATE_TABLE_USED)
SQLSTATE = HY000
Message = "You can't specify target table 'x'
for update in FROM clause"
```

This error occurs in cases such as the following:

```
UPDATE t1 SET column2 = (SELECT MAX(column1) FROM t1);
```

You can use a subquery for assignment within an [UPDATE](#) statement because subqueries are legal in [UPDATE](#) and [DELETE](#) statements as well as in [SELECT](#) statements. However, you cannot use the same table (in this case, table `t1`) for both the subquery's [FROM](#) clause and the update target.

For transactional storage engines, the failure of a subquery causes the entire statement to fail. For non-transactional storage engines, data modifications made before the error was encountered are preserved.

13.2.8.10. Optimizing Subqueries

Development is ongoing, so no optimization tip is reliable for the long term. The following list provides some interesting tricks that you might want to play with:

- Use subquery clauses that affect the number or order of the rows in the subquery. For example:

```
SELECT * FROM t1 WHERE t1.column1 IN
(SELECT column1 FROM t2 ORDER BY column1);
SELECT * FROM t1 WHERE t1.column1 IN
(SELECT DISTINCT column1 FROM t2);
SELECT * FROM t1 WHERE EXISTS
(SELECT * FROM t2 LIMIT 1);
```

- Replace a join with a subquery. For example, try this:

```
SELECT DISTINCT column1 FROM t1 WHERE t1.column1 IN (
SELECT column1 FROM t2);
```

Instead of this:

```
SELECT DISTINCT t1.column1 FROM t1, t2
WHERE t1.column1 = t2.column1;
```

- Some subqueries can be transformed to joins for compatibility with older versions of MySQL that do not support subqueries. However, in some cases, converting a subquery to a join may improve performance. See [Section 13.2.8.11, “Rewriting Subqueries as Joins for Earlier MySQL Versions”](#).
- Move clauses from outside to inside the subquery. For example, use this query:

```
SELECT * FROM t1
WHERE s1 IN (SELECT s1 FROM t1 UNION ALL SELECT s1 FROM t2);
```

Instead of this query:

```
SELECT * FROM t1
WHERE s1 IN (SELECT s1 FROM t1) OR s1 IN (SELECT s1 FROM t2);
```

For another example, use this query:

```
SELECT (SELECT column1 + 5 FROM t1) FROM t2;
```

Instead of this query:

```
SELECT (SELECT column1 FROM t1) + 5 FROM t2;
```

- Use a row subquery instead of a correlated subquery. For example, use this query:

```
SELECT * FROM t1
WHERE (column1,column2) IN (SELECT column1,column2 FROM t2);
```

Instead of this query:

```
SELECT * FROM t1
WHERE EXISTS (SELECT * FROM t2 WHERE t2.column1=t1.column1
AND t2.column2=t1.column2);
```

- Use `NOT (a = ANY (...))` rather than `a <> ALL (...)`.
- Use `x = ANY (table containing (1,2))` rather than `x=1 OR x=2`.
- Use `= ANY` rather than `EXISTS`.
- For uncorrelated subqueries that always return one row, `IN` is always slower than `=`. For example, use this query:

```
SELECT * FROM t1 WHERE t1.col_name
= (SELECT a FROM t2 WHERE b = some_const);
```

Instead of this query:

```
SELECT * FROM t1 WHERE t1.col_name
IN (SELECT a FROM t2 WHERE b = some_const);
```

These tricks might cause programs to go faster or slower. Using MySQL facilities like the `BENCHMARK()` function, you can get an idea about what helps in your own situation. See [Section 12.10.3, “Information Functions”](#).

Some optimizations that MySQL itself makes are:

- MySQL executes non-correlated subqueries only once. Use `EXPLAIN` to make sure that a given subquery really is non-correlated.
- MySQL rewrites `IN`, `ALL`, `ANY`, and `SOME` subqueries in an attempt to take advantage of the possibility that the select-list columns in the subquery are indexed.
- MySQL replaces subqueries of the following form with an index-lookup function, which `EXPLAIN` describes as a special join type (`unique_subquery` or `index_subquery`):

```
... IN (SELECT indexed_column FROM single_table ...)
```

- MySQL enhances expressions of the following form with an expression involving `MIN()` or `MAX()`, unless `NULL` values or empty sets are involved:

```
value {ALL|ANY|SOME} {> | < | >= | <=} (non-correlated subquery)
```

For example, this `WHERE` clause:

```
WHERE 5 > ALL (SELECT x FROM t)
```

might be treated by the optimizer like this:

```
WHERE 5 > (SELECT MAX(x) FROM t)
```

There is a chapter titled “How MySQL Transforms Subqueries” in the MySQL Internals Manual, available at <http://dev.mysql.com/doc/>.

13.2.8.11. Rewriting Subqueries as Joins for Earlier MySQL Versions

In previous versions of MySQL (prior to MySQL 4.1), only nested queries of the form `INSERT ... SELECT ...` and `REPLACE ... SELECT ...` were supported. Although this is not the case in MySQL 5.1, it is still true that there are sometimes other ways to test membership in a set of values. It is also true that on some occasions, it is not only possible to rewrite a query without a subquery, but it can be more efficient to make use of some of these techniques rather than to use subqueries. One of these is the `IN()` construct:

For example, this query:

```
SELECT * FROM t1 WHERE id IN (SELECT id FROM t2);
```

Can be rewritten as:

```
SELECT DISTINCT t1.* FROM t1, t2 WHERE t1.id=t2.id;
```

The queries:

```
SELECT * FROM t1 WHERE id NOT IN (SELECT id FROM t2);
SELECT * FROM t1 WHERE NOT EXISTS (SELECT id FROM t2 WHERE t1.id=t2.id);
```

Can be rewritten using `IN()`:

```
SELECT table1.* FROM table1 LEFT JOIN table2 ON table1.id=table2.id
WHERE table2.id IS NULL;
```

A `LEFT [OUTER] JOIN` can be faster than an equivalent subquery because the server might be able to optimize it better — a fact that is not specific to MySQL Server alone. Prior to SQL-92, outer joins did not exist, so subqueries were the only way to do certain things. Today, MySQL Server and many other modern database systems offer a wide range of outer join types.

MySQL Server supports multiple-table `DELETE` statements that can be used to efficiently delete rows based on information from one table or even from many tables at the same time. Multiple-table `UPDATE` statements are also supported.

13.2.9. TRUNCATE Syntax

```
TRUNCATE [TABLE] tbl_name
```

`TRUNCATE TABLE` empties a table completely. Logically, this is equivalent to a `DELETE` statement that deletes all rows, but there are practical differences under some circumstances.

For `InnoDB` tables, `TRUNCATE TABLE` is mapped to `DELETE` if there are foreign key constraints that reference the table; otherwise fast truncation (dropping and re-creating the table) is used. The `AUTO_INCREMENT` counter is reset by `TRUNCATE TABLE`, regardless of whether there is a foreign key constraint.

For other storage engines, `TRUNCATE TABLE` differs from `DELETE` in the following ways in MySQL 5.1:

- Truncate operations drop and re-create the table, which is much faster than deleting rows one by one.
- Truncate operations are not transaction-safe; an error occurs when attempting one in the course of an active transaction or active table lock.
- The number of deleted rows is not returned.
- As long as the table format file `tbl_name.frm` is valid, the table can be re-created as an empty table with `TRUNCATE TABLE`, even if the data or index files have become corrupted.
- The table handler does not remember the last used `AUTO_INCREMENT` value, but starts counting from the beginning. This is true even for `MyISAM` and `InnoDB`, which normally do not reuse sequence values.
- When used with partitioned tables, `TRUNCATE TABLE` preserves the partitioning; that is, the data and index files are dropped and re-created, while the partition definitions (`.par`) file is unaffected.

Since truncation of a table does not make any use of `DELETE`, the `TRUNCATE` statement does not invoke `ON DELETE` triggers.

`TRUNCATE TABLE` is an Oracle SQL extension adopted in MySQL.

13.2.10. UPDATE Syntax

Single-table syntax:

```
UPDATE [LOW_PRIORITY] [IGNORE] tbl_name
  SET col_name1=expr1 [, col_name2=expr2 ...]
  [WHERE where_condition]
  [ORDER BY ...]
  [LIMIT row_count]
```

Multiple-table syntax:

```
UPDATE [LOW_PRIORITY] [IGNORE] table_references
  SET col_name1=expr1 [, col_name2=expr2 ...]
  [WHERE where_condition]
```

For the single-table syntax, the `UPDATE` statement updates columns of existing rows in `tbl_name` with new values. The `SET` clause indicates which columns to modify and the values they should be given. The `WHERE` clause, if given, specifies the conditions that identify which rows to update. With no `WHERE` clause, all rows are updated. If the `ORDER BY` clause is specified, the rows are updated in the order that is specified. The `LIMIT` clause places a limit on the number of rows that can be updated.

For the multiple-table syntax, `UPDATE` updates rows in each table named in `table_references`

that satisfy the conditions. In this case, `ORDER BY` and `LIMIT` cannot be used.

where_condition is an expression that evaluates to true for each row to be updated. It is specified as described in [Section 13.2.7, “SELECT Syntax”](#).

The `UPDATE` statement supports the following modifiers:

- If you use the `LOW_PRIORITY` keyword, execution of the `UPDATE` is delayed until no other clients are reading from the table.
- If you use the `IGNORE` keyword, the update statement does not abort even if errors occur during the update. Rows for which duplicate-key conflicts occur are not updated. Rows for which columns are updated to values that would cause data conversion errors are updated to the closest valid values instead.

If you access a column from *tbl_name* in an expression, `UPDATE` uses the current value of the column. For example, the following statement sets the `age` column to one more than its current value:

```
UPDATE persondata SET age=age+1;
```

Single-table `UPDATE` assignments are generally evaluated from left to right. For multiple-table updates, there is no guarantee that assignments are carried out in any particular order.

If you set a column to the value it currently has, MySQL notices this and does not update it.

If you update a column that has been declared `NOT NULL` by setting to `NULL`, the column is set to the default value appropriate for the data type and the warning count is incremented. The default value is `0` for numeric types, the empty string (`' '`) for string types, and the “zero” value for date and time types.

`UPDATE` returns the number of rows that were actually changed. The `mysql_info()` C API function returns the number of rows that were matched and updated and the number of warnings that occurred during the `UPDATE`.

You can use `LIMIT row_count` to restrict the scope of the `UPDATE`. A `LIMIT` clause is a row-matched restriction. The statement stops as soon as it has found *row_count* rows that satisfy the `WHERE` clause, whether or not they actually were changed.

If an `UPDATE` statement includes an `ORDER BY` clause, the rows are updated in the order specified by the clause. This can be useful in certain situations that might otherwise result in an error. Suppose that a table `t` contains a column `id` that has a unique index. The following statement could fail with a duplicate-key error, depending on the order in which rows are updated:

```
UPDATE t SET id = id + 1;
```

For example, if the table contains 1 and 2 in the `id` column and 1 is updated to 2 before 2 is updated to 3, an error occurs. To avoid this problem, add an `ORDER BY` clause to cause the rows with larger `id` values to be updated before those with smaller values:

```
UPDATE t SET id = id + 1 ORDER BY id DESC;
```

You can also perform `UPDATE` operations covering multiple tables. However, you cannot use `ORDER BY` or `LIMIT` with a multiple-table `UPDATE`. The *table_references* clause lists the tables involved in the join. Its syntax is described in [Section 13.2.7.1, “JOIN Syntax”](#). Here is an example:

```
UPDATE items,month SET items.price=month.price
WHERE items.id=month.id;
```

The preceding example shows an inner join that uses the comma operator, but multiple-table `UPDATE` statements can use any type of join allowed in `SELECT` statements, such as `LEFT JOIN`.

You need the `UPDATE` privilege only for columns referenced in a multiple-table `UPDATE` that are actually updated. You need only the `SELECT` privilege for any columns that are read but not modified.

If you use a multiple-table `UPDATE` statement involving `InnoDB` tables for which there are foreign key constraints, the MySQL optimizer might process tables in an order that differs from that of their parent/child relationship. In this case, the statement fails and rolls back. Instead, update a single table and rely on the `ON UPDATE` capabilities that `InnoDB` provides to cause the other tables to be modified accordingly. See [Section 14.5.6.4, “FOREIGN KEY Constraints”](#).

Currently, you cannot update a table and select from the same table in a subquery.

13.3. MySQL Utility Statements

13.3.1. DESCRIBE Syntax

```
{DESCRIBE | DESC} tbl_name [col_name | wild]
```

`DESCRIBE` provides information about the columns in a table. It is a shortcut for `SHOW COLUMNS FROM`. These statements also display information for views. (See [Section 13.5.4.4, “SHOW COLUMNS Syntax”](#).)

`col_name` can be a column name, or a string containing the SQL `'%'` and `'_'` wildcard characters to obtain output only for the columns with names matching the string. There is no need to enclose the string within quotes unless it contains spaces or other special characters.

```
mysql> DESCRIBE city;
```

Field	Type	Null	Key	Default	Extra
Id	int(11)	NO	PRI	NULL	auto_increment
Name	char(35)	NO			
Country	char(3)	NO	UNI		
District	char(20)	YES	MUL		
Population	int(11)	NO		0	

5 rows in set (0.00 sec)

`Field` indicates the column name.

The `Null` field indicates whether `NULL` values can be stored in the column.

The `Key` field indicates whether the column is indexed. A value of `PRI` indicates that the column is part of the table's primary key. `UNI` indicates that the column is part of a `UNIQUE` index. The `MUL` value indicates that multiple occurrences of a given value are allowed within the column.

One reason for `MUL` to be displayed on a `UNIQUE` index is that several columns form a composite `UNIQUE` index; although the combination of the columns is unique, each column can still hold multiple occurrences of a given value. Note that in a composite index, only the leftmost column of the index has an entry in the `Key` field.

The `Default` field indicates the default value that is assigned to the column.

The `Extra` field contains any additional information that is available about a given column. In the example shown, the `Extra` field indicates that the `Id` column was created with the `AUTO_INCREMENT` keyword.

The `DESCRIBE` statement is provided for compatibility with Oracle.

The `SHOW CREATE TABLE` and `SHOW TABLE STATUS` statements also provide information about tables. See [Section 13.5.4, “SHOW Syntax”](#).

13.3.2. HELP Syntax

```
HELP 'search_string'
```

The `HELP` statement returns online information from the MySQL Reference manual. Its proper operation requires that the help tables in the `mysql` database be initialized with help topic information (see [Section 5.2.8, “Server-Side Help”](#)).

The `HELP` statement searches the help tables for the given search string and displays the result of the search. The search string is not case sensitive.

The `HELP` statement understands several types of search strings:

- At the most general level, use `contents` to retrieve a list of the top-level help categories:

```
HELP 'contents'
```

- For a list of topics in a given help category, such as `Data Types`, use the category name:

```
HELP 'data types'
```

- For help on a specific help topic, such as as the `ASCII ()` function or the `CREATE TABLE` statement, use the associated keyword or keywords:

```
HELP 'ascii'
HELP 'create table'
```

In other words, the search string matches a category, many topics, or a single topic. You cannot necessarily tell in advance whether a given search string will return a list of items or the help information for a single help topic. However, you can tell what kind of response `HELP` returned by examining the number of rows and columns in the result set.

The following descriptions indicate the forms that the result set can take. Output for the example statements is shown using the familiar “tabular” or “vertical” format that you see when using the `mysql` client, but note that `mysql` itself reformats `HELP` result sets in a different way.

- Empty result set

No match could be found for the search string.

- Result set containing a single row with three columns

This means that the search string yielded a hit for the help topic. The result has three columns:

- `name`: The topic name.
- `description`: Descriptive help text for the topic.
- `example`: Usage example or examples. This column might be blank.

Example: `HELP 'replace'`

Yields:

```
name: REPLACE
description: Syntax:
REPLACE(str,from_str,to_str)

Returns the string str with all occurrences of the string from_str
replaced by the string to_str. REPLACE() performs a case-sensitive
match when searching for from_str.
example: mysql> SELECT REPLACE('www.mysql.com', 'w', 'Ww');
-> 'WwWwWw.mysql.com'
```

- Result set containing multiple rows with two columns

This means that the search string matched many help topics. The result set indicates the help topic names:

- `name`: The help topic name.
- `is_it_category`: `Y` if the name represents a help category, `N` if it does not. If it does not, the `name` value when specified as the argument to the `HELP` statement should yield a single-row result set containing a description for the named item.

Example: `HELP 'status'`

Yields:

name	is_it_category
SHOW	N
SHOW ENGINE	N
SHOW INNODB STATUS	N
SHOW MASTER STATUS	N
SHOW PROCEDURE STATUS	N
SHOW SLAVE STATUS	N
SHOW STATUS	N
SHOW TABLE STATUS	N

- Result set containing multiple rows with three columns

This means the search string matches a category. The result set contains category entries:

- `source_category_name`: The help category name.
- `name`: The category or topic name
- `is_it_category`: `Y` if the name represents a help category, `N` if it does not. If it does not, the `name` value when specified as the argument to the `HELP` statement should yield a single-row result set containing a description for the named item.

Example: `HELP 'functions'`

Yields:

source_category_name	name	is_it_category
Functions	CREATE FUNCTION	N
Functions	DROP FUNCTION	N
Functions	Bit Functions	Y
Functions	Comparison operators	Y

Functions	Control flow functions	Y
Functions	Date and Time Functions	Y
Functions	Encryption Functions	Y
Functions	Information Functions	Y
Functions	Logical operators	Y
Functions	Miscellaneous Functions	Y
Functions	Numeric Functions	Y
Functions	String Functions	Y

13.3.3. USE Syntax

```
USE db_name
```

The `USE db_name` statement tells MySQL to use the *db_name* database as the default (current) database for subsequent statements. The database remains the default until the end of the session or another `USE` statement is issued:

```
USE db1;
SELECT COUNT(*) FROM mytable; # selects from db1.mytable
USE db2;
SELECT COUNT(*) FROM mytable; # selects from db2.mytable
```

Making a particular database the default by means of the `USE` statement does not preclude you from accessing tables in other databases. The following example accesses the `author` table from the `db1` database and the `editor` table from the `db2` database:

```
USE db1;
SELECT author_name,editor_name FROM author,db2.editor
WHERE author.editor_id = db2.editor.editor_id;
```

The `USE` statement is provided for compatibility with Sybase.

13.4. MySQL Transactional and Locking Statements

MySQL supports local transactions (within a given client connection) through statements such as `SET AUTOCOMMIT`, `START TRANSACTION`, `COMMIT`, and `ROLLBACK`. See [Section 13.4.1, “START TRANSACTION, COMMIT, and ROLLBACK Syntax”](#). XA transaction support enables MySQL to participate in distributed transactions as well. See [Section 13.4.7, “XA Transactions”](#).

13.4.1. START TRANSACTION, COMMIT, and ROLLBACK Syntax

```
START TRANSACTION | BEGIN [WORK]
COMMIT [WORK] [AND [NO] CHAIN] [[NO] RELEASE]
ROLLBACK [WORK] [AND [NO] CHAIN] [[NO] RELEASE]
SET AUTOCOMMIT = {0 | 1}
```

The `START TRANSACTION` and `BEGIN` statement begin a new transaction. `COMMIT` commits the current transaction, making its changes permanent. `ROLLBACK` rolls back the current transaction, canceling its changes. The `SET AUTOCOMMIT` statement disables or enables the default autocommit mode for the current connection.

The optional `WORK` keyword is supported for `COMMIT` and `RELEASE`, as are the `CHAIN` and `RELEASE` clauses. `CHAIN` and `RELEASE` can be used for additional control over transaction completion. The value of the `completion_type` system variable determines the default completion behavior. See [Section 5.2.3, “System Variables”](#).

The `AND CHAIN` clause causes a new transaction to begin as soon as the current one ends, and the new transaction has the same isolation level as the just-terminated transaction. The `RELEASE` clause causes the server to disconnect the current client connection after terminating the current transaction. Including the `NO` keyword suppresses `CHAIN` or `RELEASE` completion, which can be useful if the `completion_type` system variable is set to cause chaining or release completion by default.

By default, MySQL runs with autocommit mode enabled. This means that as soon as you execute a statement that updates (modifies) a table, MySQL stores the update on disk.

If you are using a transaction-safe storage engine (such as `InnoDB`, or `NDB Cluster`), you can disable autocommit mode with the following statement:

```
SET AUTOCOMMIT=0;
```

After disabling autocommit mode by setting the `AUTOCOMMIT` variable to zero, you must use `COMMIT` to store your changes to disk or `ROLLBACK` if you want to ignore the changes you have made since the beginning of your transaction.

To disable autocommit mode for a single series of statements, use the `START TRANSACTION` statement:

```
START TRANSACTION;
SELECT @A:=SUM(salary) FROM table1 WHERE type=1;
UPDATE table2 SET summary=@A WHERE type=1;
COMMIT;
```

With `START TRANSACTION`, autocommit remains disabled until you end the transaction with `COMMIT` or `ROLLBACK`. The autocommit mode then reverts to its previous state.

`BEGIN` and `BEGIN WORK` are supported as aliases of `START TRANSACTION` for initiating a transaction. `START TRANSACTION` is standard SQL syntax and is the recommended way to start an ad-hoc transaction.

The `BEGIN` statement differs from the use of the `BEGIN` keyword that starts a `BEGIN ... END` compound statement. The latter does not begin a transaction. See [Section 18.2.5, “BEGIN ... END Compound Statement Syntax”](#).

You can also begin a transaction like this:

```
START TRANSACTION WITH CONSISTENT SNAPSHOT;
```

The `WITH CONSISTENT SNAPSHOT` clause starts a consistent read for storage engines that are capable of it. Currently, this applies only to `InnoDB`. The effect is the same as issuing a `START TRANSACTION` followed by a `SELECT` from any `InnoDB` table. See [Section 14.5.10.4, “Consistent Non-Locking Read”](#).

The `WITH CONSISTENT SNAPSHOT` clause does not change the current transaction isolation level, so it provides a consistent snapshot only if the current isolation level is one that allows consistent read (`REPEATABLE READ` or `SERIALIZABLE`).

Beginning a transaction causes an implicit `UNLOCK TABLES` to be performed.

For best results, transactions should be performed using only tables managed by a single transactional storage engine. Otherwise, the following problems can occur:

- If you use tables from more than one transaction-safe storage engine (such as `InnoDB`), and the transaction isolation level is not `SERIALIZABLE`, it is possible that when one transaction commits,

another ongoing transaction that uses the same tables will see only some of the changes made by the first transaction. That is, the atomicity of transactions is not guaranteed with mixed engines and inconsistencies can result. (If mixed-engine transactions are infrequent, you can use `SET TRANSACTION ISOLATION LEVEL` to set the isolation level to `SERIALIZABLE` on a per-transaction basis as necessary.)

- If you use non-transaction-safe tables within a transaction, any changes to those tables are stored at once, regardless of the status of autocommit mode.

If you issue a `ROLLBACK` statement after updating a non-transactional table within a transaction, an `ER_WARNING_NOT_COMPLETE_ROLLBACK` warning occurs. Changes to transaction-safe tables are rolled back, but not changes to non-transaction-safe tables.

Each transaction is stored in the binary log in one chunk, upon `COMMIT`. Transactions that are rolled back are not logged. (**Exception:** Modifications to non-transactional tables cannot be rolled back. If a transaction that is rolled back includes modifications to non-transactional tables, the entire transaction is logged with a `ROLLBACK` statement at the end to ensure that the modifications to those tables are replicated.) See [Section 5.12.4, “The Binary Log”](#).

You can change the isolation level for transactions with `SET TRANSACTION ISOLATION LEVEL`. See [Section 13.4.6, “SET TRANSACTION Syntax”](#).

Rolling back can be a slow operation that may occur without the user having explicitly asked for it (for example, when an error occurs). Because of this, `SHOW PROCESSLIST` displays `Rolling back` in the `State` column for the connection during implicit and explicit (`ROLLBACK` SQL statement) roll-backs.

13.4.2. Statements That Cannot Be Rolled Back

Some statements cannot be rolled back. In general, these include data definition language (DDL) statements, such as those that create or drop databases, those that create, drop, or alter tables or stored routines.

You should design your transactions not to include such statements. If you issue a statement early in a transaction that cannot be rolled back, and then another statement later fails, the full effect of the transaction cannot be rolled back in such cases by issuing a `ROLLBACK` statement.

13.4.3. Statements That Cause an Implicit Commit

Each of the following statements (and any synonyms for them) implicitly end a transaction, as if you had done a `COMMIT` before executing the statement:

- `ALTER FUNCTION`, `ALTER PROCEDURE`, `ALTER TABLE`, `BEGIN`, `CREATE DATABASE`, `CREATE FUNCTION`, `CREATE INDEX`, `CREATE PROCEDURE`, `CREATE TABLE`, `DROP DATABASE`, `DROP FUNCTION`, `DROP INDEX`, `DROP PROCEDURE`, `DROP TABLE`, `LOAD MASTER DATA`, `LOCK TABLES`, `LOAD DATA INFILE`, `RENAME TABLE`, `SET AUTOCOMMIT=1`, `START TRANSACTION`, `TRUNCATE TABLE`, `UNLOCK TABLES`.
- `UNLOCK TABLES` commits a transaction only if any tables currently are locked.
- The `CREATE TABLE` statement in `InnoDB` is processed as a single transaction. This means that a `ROLLBACK` from the user does not undo `CREATE TABLE` statements the user made during that transaction.
- In MySQL 5.1.11 and earlier, `LOAD DATA INFILE` caused an implicit commit for all storage engines. Beginning with MySQL 5.1.12, it causes an implicit commit only for tables using the `NDB`

storage engine. For more information, see [Bug#11151](http://bugs.mysql.com/11151) [http://bugs.mysql.com/11151].

Transactions cannot be nested. This is a consequence of the implicit `COMMIT` performed for any current transaction when you issue a `START TRANSACTION` statement or one of its synonyms.

Statements that cause implicit cannot be used in an XA transaction while the transaction is in an `ACTIVE` state.

13.4.4. `SAVEPOINT` and `ROLLBACK TO SAVEPOINT` Syntax

```
SAVEPOINT identifier
ROLLBACK [WORK] TO SAVEPOINT identifier
RELEASE SAVEPOINT identifier
```

InnoDB supports the SQL statements `SAVEPOINT`, `ROLLBACK TO SAVEPOINT`, `RELEASE SAVEPOINT` and the optional `WORK` keyword for `ROLLBACK`.

The `SAVEPOINT` statement sets a named transaction savepoint with a name of *identifier*. If the current transaction has a savepoint with the same name, the old savepoint is deleted and a new one is set.

The `ROLLBACK TO SAVEPOINT` statement rolls back a transaction to the named savepoint. Modifications that the current transaction made to rows after the savepoint was set are undone in the rollback, but InnoDB does *not* release the row locks that were stored in memory after the savepoint. (Note that for a new inserted row, the lock information is carried by the transaction ID stored in the row; the lock is not separately stored in memory. In this case, the row lock is released in the undo.) Savepoints that were set at a later time than the named savepoint are deleted.

If the `ROLLBACK TO SAVEPOINT` statement returns the following error, it means that no savepoint with the specified name exists:

```
ERROR 1181: Got error 153 during ROLLBACK
```

The `RELEASE SAVEPOINT` statement removes the named savepoint from the set of savepoints of the current transaction. No commit or rollback occurs. It is an error if the savepoint does not exist.

All savepoints of the current transaction are deleted if you execute a `COMMIT`, or a `ROLLBACK` that does not name a savepoint.

Beginning with MySQL 5.0.17, a new savepoint level is created when a stored function is invoked or a trigger is activated. The savepoints on previous levels become unavailable and thus do not conflict with savepoints on the new level. When the function or trigger terminates, any savepoints it created are released and the previous savepoint level is restored.

13.4.5. `LOCK TABLES` and `UNLOCK TABLES` Syntax

```
LOCK TABLES
  tbl_name [AS alias] {READ [LOCAL] | [LOW_PRIORITY] WRITE}
  [, tbl_name [AS alias] {READ [LOCAL] | [LOW_PRIORITY] WRITE}] ...
UNLOCK TABLES
```

`LOCK TABLES` locks base tables (but not views) for the current thread. If any of the tables are locked by other threads, it blocks until all locks can be acquired. `UNLOCK TABLES` releases any locks held by the current thread. All tables that are locked by the current thread are implicitly unlocked when the thread issues another `LOCK TABLES`, or when the connection to the server is closed.

A table lock protects only against inappropriate reads or writes by other clients. The client holding the lock, even a read lock, can perform table-level operations such as `DROP TABLE`. Truncate operations

are not transaction-safe, so an error occurs if the client attempts one during an active transaction or while holding a table lock.

Note the following regarding the use of `LOCK TABLES` with transactional tables:

- `LOCK TABLES` is not transaction-safe and implicitly commits any active transactions before attempting to lock the tables. Also, beginning a transaction (for example, with `START TRANSACTION`) implicitly performs an `UNLOCK TABLES`. (See Section 13.4.3, “Statements That Cause an Implicit Commit”.)
- The correct way to use `LOCK TABLES` with transactional tables, such as `InnoDB` tables, is to set `AUTOCOMMIT = 0` and not to call `UNLOCK TABLES` until you commit the transaction explicitly. When you call `LOCK TABLES`, `InnoDB` internally takes its own table lock, and MySQL takes its own table lock. `InnoDB` releases its table lock at the next commit, but for MySQL to release its table lock, you have to call `UNLOCK TABLES`. You should not have `AUTOCOMMIT = 1`, because then `InnoDB` releases its table lock immediately after the call of `LOCK TABLES`, and deadlocks can very easily happen. Note that we do not acquire the `InnoDB` table lock at all if `AUTOCOMMIT=1`, to help old applications avoid unnecessary deadlocks.
- `ROLLBACK` does not release MySQL's non-transactional table locks.

To use `LOCK TABLES`, you must have the `LOCK TABLES` privilege and the `SELECT` privilege for the involved tables.

The main reasons to use `LOCK TABLES` are to emulate transactions or to get more speed when updating tables. This is explained in more detail later.

If a thread obtains a `READ` lock on a table, that thread (and all other threads) can only read from the table. If a thread obtains a `WRITE` lock on a table, only the thread holding the lock can write to the table. Other threads are blocked from reading or writing the table until the lock has been released.

The difference between `READ LOCAL` and `READ` is that `READ LOCAL` allows non-conflicting `INSERT` statements (concurrent inserts) to execute while the lock is held. However, this cannot be used if you are going to manipulate the database files outside MySQL while you hold the lock. For `InnoDB` tables, `READ LOCAL` is the same as `READ`.

When you use `LOCK TABLES`, you must lock all tables that you are going to use in your queries. Because `LOCK TABLES` will not lock views, if the operation that you are performing uses any views, you must also lock all of the base tables on which those views depend. While the locks obtained with a `LOCK TABLES` statement are in effect, you cannot access any tables that were not locked by the statement. Also, you cannot use a locked table multiple times in a single query. Use aliases instead, in which case you must obtain a lock for each alias separately.

```
mysql> LOCK TABLE t WRITE, t AS t1 WRITE;
mysql> INSERT INTO t SELECT * FROM t;
ERROR 1100: Table 't' was not locked with LOCK TABLES
mysql> INSERT INTO t SELECT * FROM t AS t1;
```

If your queries refer to a table by means of an alias, you must lock the table using that same alias. It does not work to lock the table without specifying the alias:

```
mysql> LOCK TABLE t READ;
mysql> SELECT * FROM t AS myalias;
ERROR 1100: Table 'myalias' was not locked with LOCK TABLES
```

Conversely, if you lock a table using an alias, you must refer to it in your queries using that alias:

```
mysql> LOCK TABLE t AS myalias READ;
mysql> SELECT * FROM t;
```

```
ERROR 1100: Table 't' was not locked with LOCK TABLES
mysql> SELECT * FROM t AS myalias;
```

WRITE locks normally have higher priority than **READ** locks to ensure that updates are processed as soon as possible. This means that if one thread obtains a **READ** lock and then another thread requests a **WRITE** lock, subsequent **READ** lock requests wait until the **WRITE** thread has gotten the lock and released it. You can use **LOW_PRIORITY WRITE** locks to allow other threads to obtain **READ** locks while the thread is waiting for the **WRITE** lock. You should use **LOW_PRIORITY WRITE** locks only if you are sure that eventually there will be a time when no threads have a **READ** lock.

LOCK TABLES works as follows:

1. Sort all tables to be locked in an internally defined order. From the user standpoint, this order is undefined.
2. If a table is locked with a read and a write lock, put the write lock before the read lock.
3. Lock one table at a time until the thread gets all locks.

This policy ensures that table locking is deadlock free. There are, however, other things you need to be aware of about this policy: If you are using a **LOW_PRIORITY WRITE** lock for a table, it means only that MySQL waits for this particular lock until there are no threads that want a **READ** lock. When the thread has gotten the **WRITE** lock and is waiting to get the lock for the next table in the lock table list, all other threads wait for the **WRITE** lock to be released. If this becomes a serious problem with your application, you should consider converting some of your tables to transaction-safe tables.

You can safely use **KILL** to terminate a thread that is waiting for a table lock. See [Section 13.5.5.3, “KILL Syntax”](#).

Note that you should *not* lock any tables that you are using with **INSERT DELAYED** because in that case the **INSERT** is performed by a separate thread.

Normally, you do not need to lock tables, because all single **UPDATE** statements are atomic; no other thread can interfere with any other currently executing SQL statement. However, there are a few cases when locking tables may provide an advantage:

- If you are going to run many operations on a set of **MyISAM** tables, it is much faster to lock the tables you are going to use. Locking **MyISAM** tables speeds up inserting, updating, or deleting on them. The downside is that no thread can update a **READ**-locked table (including the one holding the lock) and no thread can access a **WRITE**-locked table other than the one holding the lock.

The reason some **MyISAM** operations are faster under **LOCK TABLES** is that MySQL does not flush the key cache for the locked tables until **UNLOCK TABLES** is called. Normally, the key cache is flushed after each SQL statement.

- If you are using a storage engine in MySQL that does not support transactions, you must use **LOCK TABLES** if you want to ensure that no other thread comes between a **SELECT** and an **UPDATE**. The example shown here requires **LOCK TABLES** to execute safely:

```
LOCK TABLES trans READ, customer WRITE;
SELECT SUM(value) FROM trans WHERE customer_id=some_id;
UPDATE customer
  SET total_value=sum_from_previous_statement
  WHERE customer_id=some_id;
UNLOCK TABLES;
```

Without **LOCK TABLES**, it is possible that another thread might insert a new row in the **trans** ta-

ble between execution of the `SELECT` and `UPDATE` statements.

You can avoid using `LOCK TABLES` in many cases by using relative updates (`UPDATE customer SET value=value+new_value`) or the `LAST_INSERT_ID()` function. See [Section 1.9.5.3, “Transactions and Atomic Operations”](#).

You can also avoid locking tables in some cases by using the user-level advisory lock functions `GET_LOCK()` and `RELEASE_LOCK()`. These locks are saved in a hash table in the server and implemented with `pthread_mutex_lock()` and `pthread_mutex_unlock()` for high speed. See [Section 12.10.4, “Miscellaneous Functions”](#).

See [Section 7.3.1, “Locking Methods”](#), for more information on locking policy.

You can lock all tables in all databases with read locks with the `FLUSH TABLES WITH READ LOCK` statement. See [Section 13.5.5.2, “FLUSH Syntax”](#). This is a very convenient way to get backups if you have a filesystem such as Veritas that can take snapshots in time.

Note: If you use `ALTER TABLE` on a locked table, it may become unlocked. See [Section A.7.1, “Problems with ALTER TABLE”](#).

13.4.6. SET TRANSACTION Syntax

```
SET [GLOBAL | SESSION] TRANSACTION ISOLATION LEVEL
{ READ UNCOMMITTED | READ COMMITTED | REPEATABLE READ | SERIALIZABLE }
```

This statement sets the transaction isolation level for the next transaction, globally, or for the current session.

The default behavior of `SET TRANSACTION` is to set the isolation level for the next (not yet started) transaction. If you use the `GLOBAL` keyword, the statement sets the default transaction level globally for all new connections created from that point on. Existing connections are unaffected. You need the `SUPER` privilege to do this. Using the `SESSION` keyword sets the default transaction level for all future transactions performed on the current connection.

For descriptions of each InnoDB transaction isolation level, see [Section 14.5.10.3, “InnoDB and TRANSACTION ISOLATION LEVEL”](#). InnoDB supports each of these levels in MySQL 5.1. The default level is `REPEATABLE READ`.

To set the initial default global isolation level for `mysqld`, use the `--transaction-isolation` option. See [Section 5.2.2, “Command Options”](#).

13.4.7. XA Transactions

Support for XA transactions is available for the InnoDB storage engine. The MySQL XA implementation is based on the X/Open CAE document *Distributed Transaction Processing: The XA Specification*. This document is published by The Open Group and available at <http://www.opengroup.org/public/pubs/catalog/c193.htm>. Limitations of the current XA implementation are described in [Section I.5, “Restrictions on XA Transactions”](#).

On the client side, there are no special requirements. The XA interface to a MySQL server consists of SQL statements that begin with the `XA` keyword. MySQL client programs must be able to send SQL statements and to understand the semantics of the XA statement interface. They do not need be linked against a recent client library. Older client libraries also will work.

Currently, among the MySQL Connectors, MySQL Connector/J 5.0.0 supports XA directly (by means of a class interface that handles the XA SQL statement interface for you).

XA supports distributed transactions; that is, the ability to allow multiple separate transactional resources to participate in a global transaction. Transactional resources often are RDBMSs but may be other kinds of resources.

A global transaction involves several actions that are transactional in themselves, but that all must either complete successfully as a group, or all be rolled back as a group. In essence, this extends ACID properties “up a level” so that multiple ACID transactions can be executed in concert as components of a global operation that also has ACID properties. (However, for a distributed transaction, you must use the [SERIALIZABLE](#) isolation level to achieve ACID properties. It is enough to use [REPEATABLE READ](#) for a non-distributed transaction, but not for a distributed transaction.)

Some examples of distributed transactions:

- An application may act as an integration tool that combines a messaging service with an RDBMS. The application makes sure that transactions dealing with message sending, retrieval, and processing that also involve a transactional database all happen in a global transaction. You can think of this as “transactional email.”
- An application performs actions that involve different database servers, such as a MySQL server and an Oracle server (or multiple MySQL servers), where actions that involve multiple servers must happen as part of a global transaction, rather than as separate transactions local to each server.
- A bank keeps account information in an RDBMS and distributes and receives money via automated teller machines (ATMs). It is necessary to ensure that ATM actions are correctly reflected in the accounts, but this cannot be done with the RDBMS alone. A global transaction manager integrates the ATM and database resources to ensure overall consistency of financial transactions.

Applications that use global transactions involve one or more Resource Managers and a Transaction Manager:

- A Resource Manager (RM) provides access to transactional resources. A database server is one kind of resource manager. It must be possible to either commit or roll back transactions managed by the RM.
- A Transaction Manager (TM) coordinates the transactions that are part of a global transaction. It communicates with the RMs that handle each of these transactions. The individual transactions within a global transaction are “branches” of the global transaction. Global transactions and their branches are identified by a naming scheme described later.

The MySQL implementation of XA MySQL enables a MySQL server to act as a Resource Manager that handles XA transactions within a global transaction. A client program that connects to the MySQL server acts as the Transaction Manager.

To carry out a global transaction, it is necessary to know which components are involved, and bring each component to a point when it can be committed or rolled back. Depending on what each component reports about its ability to succeed, they must all commit or roll back as an atomic group. That is, either all components must commit, or all components must roll back. To manage a global transaction, it is necessary to take into account that any component or the connecting network might fail.

The process for executing a global transaction uses two-phase commit (2PC). This takes place after the actions performed by the branches of the global transaction have been executed.

1. In the first phase, all branches are prepared. That is, they are told by the TM to get ready to commit. Typically, this means each RM that manages a branch records the actions for the branch in stable

storage. The branches indicate whether they are able to do this, and these results are used for the second phase.

2. In the second phase, the TM tells the RMs whether to commit or roll back. If all branches indicated when they were prepared that they will be able to commit, all branches are told to commit. If any branch indicated when it was prepared that it will not be able to commit, all branches are told to roll back.

In some cases, a global transaction might use one-phase commit (1PC). For example, when a Transaction Manager finds that a global transaction consists of only one transactional resource (that is, a single branch), that resource can be told to prepare and commit at the same time.

13.4.7.1. XA Transaction SQL Syntax

To perform XA transactions in MySQL, use the following statements:

```
XA {START|BEGIN} xid [JOIN|RESUME]
XA END xid [SUSPEND [FOR MIGRATE]]
XA PREPARE xid
XA COMMIT xid [ONE PHASE]
XA ROLLBACK xid
XA RECOVER
```

For `XA START`, the `JOIN` and `RESUME` clauses are not supported.

For `XA END` the `SUSPEND [FOR MIGRATE]` clause is not supported.

Each XA statement begins with the `XA` keyword, and most of them require an `xid` value. An `xid` is an XA transaction identifier. It indicates which transaction the statement applies to. `xid` values are supplied by the client, or generated by the MySQL server. An `xid` value has from one to three parts:

```
xid: gtrid [, bqual [, formatID ]]
```

`gtrid` is a global transaction identifier, `bqual` is a branch qualifier, and `formatID` is a number that identifies the format used by the `gtrid` and `bqual` values. As indicated by the syntax, `bqual` and `formatID` are optional. The default `bqual` value is `' '` if not given. The default `formatID` value is `1` if not given.

`gtrid` and `bqual` must be string literals, each up to 64 bytes (not characters) long. `gtrid` and `bqual` can be specified in several ways. You can use a quoted string (`'ab'`), hex string (`0x6162`, `X'ab'`), or bit value (`b'nnnn'`).

`formatID` is an unsigned integer.

The `gtrid` and `bqual` values are interpreted in bytes by the MySQL server's underlying XA support routines. However, while an SQL statement containing an XA statement is being parsed, the server works with some specific character set. To be safe, write `gtrid` and `bqual` as hex strings.

`xid` values typically are generated by the Transaction Manager. Values generated by one TM must be different from values generated by other TMs. A given TM must be able to recognize its own `xid` values in a list of values returned by the `XA RECOVER` statement.

`XA START xid` starts an XA transaction with the given `xid` value. Each XA transaction must have a unique `xid` value, so the value must not currently be used by another XA transaction. Uniqueness is as-

essed using the *gtrid* and *bqual* values. All following XA statements for the XA transaction must be specified using the same *xid* value as that given in the `XA START` statement. If you use any of those statements but specify an *xid* value that does not correspond to some existing XA transaction, an error occurs.

One or more XA transactions can be part of the same global transaction. All XA transactions within a given global transaction must use the same *gtrid* value in the *xid* value. For this reason, *gtrid* values must be globally unique so that there is no ambiguity about which global transaction a given XA transaction is part of. The *bqual* part of the *xid* value must be different for each XA transaction within a global transaction. (The requirement that *bqual* values be different is a limitation of the current MySQL XA implementation. It is not part of the XA specification.)

The `XA RECOVER` statement returns information for those XA transactions on the MySQL server that are in the `PREPARED` state. (See [Section 13.4.7.2, “XA Transaction States”](#).) The output includes a row for each such XA transaction on the server, regardless of which client started it.

`XA RECOVER` output rows look like this (for an example *xid* value consisting of the parts 'abc', 'def', and 7):

```
mysql> XA RECOVER;
+-----+-----+-----+-----+
| formatID | gtrid_length | bqual_length | data |
+-----+-----+-----+-----+
| 7 | 3 | 3 | abcdef |
+-----+-----+-----+-----+
```

The output columns have the following meanings:

- *formatID* is the *formatID* part of the transaction *xid*
- *gtrid_length* is the length in bytes of the *gtrid* part of the *xid*
- *bqual_length* is the length in bytes of the *bqual* part of the *xid*
- *data* is the concatenation of the *gtrid* and *bqual* parts of the *xid*

13.4.7.2. XA Transaction States

An XA transaction progresses through the following states:

1. Use `XA START` to start an XA transaction and put it in the `ACTIVE` state.
2. For an `ACTIVE` XA transaction, issue the SQL statements that make up the transaction, and then issue an `XA END` statement. `XA END` puts the transaction in the `IDLE` state.
3. For an `IDLE` XA transaction, you can issue either an `XA PREPARE` statement or an `XA COMMIT ... ONE PHASE` statement:
 - `XA PREPARE` puts the transaction in the `PREPARED` state. An `XA RECOVER` statement at this point will include the transaction's *xid* value in its output, because `XA RECOVER` lists all XA transactions that are in the `PREPARED` state.
 - `XA COMMIT ... ONE PHASE` prepares and commits the transaction. The *xid* value will not be listed by `XA RECOVER` because the transaction terminates.
4. For a `PREPARED` XA transaction, you can issue an `XA COMMIT` statement to commit and terminate the transaction, or `XA ROLLBACK` to roll back and terminate the transaction.

Here is a simple XA transaction that inserts a row into a table as part of a global transaction:

```
mysql> XA START 'xatest';
Query OK, 0 rows affected (0.00 sec)

mysql> INSERT INTO mytable (i) VALUES(10);
Query OK, 1 row affected (0.04 sec)

mysql> XA END 'xatest';
Query OK, 0 rows affected (0.00 sec)

mysql> XA PREPARE 'xatest';
Query OK, 0 rows affected (0.00 sec)

mysql> XA COMMIT 'xatest';
Query OK, 0 rows affected (0.00 sec)
```

Within the context of a given client connection, XA transactions and local (non-XA) transactions are mutually exclusive. For example, if `XA START` has been issued to begin an XA transaction, a local transaction cannot be started until the XA transaction has been committed or rolled back. Conversely, if a local transaction has been started with `START TRANSACTION`, no XA statements can be used until the transaction has been committed or rolled back.

Note that if an XA transaction is in the `ACTIVE` state, you cannot issue any statements that cause an implicit commit. That would violate the XA contract because you could not roll back the XA transaction. You will receive the following error if you try to execute such a statement:

```
ERROR 1399 (XAE07): XAER_RMFAIL: The command cannot be executed
when global transaction is in the ACTIVE state
```

Statements to which the preceding remark applies are listed at [Section 13.4.3, “Statements That Cause an Implicit Commit”](#).

13.5. Database Administration Statements

13.5.1. Account Management Statements

MySQL account information is stored in the tables of the `mysql` database. This database and the access control system are discussed extensively in [Chapter 5, *Database Administration*](#), which you should consult for additional details.

Important: Some releases of MySQL introduce changes to the structure of the grant tables to add new privileges or features. Whenever you update to a new version of MySQL, you should update your grant tables to make sure that they have the current structure so that you can take advantage of any new capabilities. See [Section 5.6.2, “mysql_upgrade — Check Tables for MySQL Upgrade”](#).

13.5.1.1. CREATE USER Syntax

```
CREATE USER user [IDENTIFIED BY [PASSWORD] 'password']
[, user [IDENTIFIED BY [PASSWORD] 'password']] ...
```

The `CREATE USER` statement creates new MySQL accounts. To use it, you must have the global `CREATE USER` privilege or the `INSERT` privilege for the `mysql` database. For each account, `CREATE USER` creates a new row in the `mysql.user` table that has no privileges. An error occurs if the account already exists. Each account is named using the same format as for the `GRANT` statement; for example, `'jeffrey'@'localhost'`. The user and host parts of the account name correspond to the `User` and `Host` column values of the `user` table row for the account.

The account can be given a password with the optional `IDENTIFIED BY` clause. The `user` value and the password are given the same way as for the `GRANT` statement. In particular, to specify the password

in plain text, omit the `PASSWORD` keyword. To specify the password as the hashed value as returned by the `PASSWORD()` function, include the `PASSWORD` keyword. See [Section 13.5.1.3, “GRANT Syntax”](#).

13.5.1.2. DROP USER Syntax

```
DROP USER user [, user] ...
```

The `DROP USER` statement removes one or more MySQL accounts. It removes privilege rows for the account from all grant tables. To use this statement, you must have the global `CREATE USER` privilege or the `DELETE` privilege for the `mysql` database. Each account is named using the same format as for the `GRANT` statement; for example, `'jeffrey'@'localhost'`. The user and host parts of the account name correspond to the `User` and `Host` column values of the `user` table row for the account.

With `DROP USER`, you can remove an account and its privileges as follows:

```
DROP USER user;
```

Important: `DROP USER` does not automatically close any open user sessions. Rather, in the event that a user with an open session is dropped, the statement does not take effect until that user's session is closed. Once the session is closed, the user is dropped, and that user's next attempt to log in will fail. *This is by design.*

13.5.1.3. GRANT Syntax

```
GRANT priv_type [(column_list)] [, priv_type [(column_list))] ...
ON [object_type] {tbl_name | * | *.* | db_name.*}
TO user [IDENTIFIED BY [PASSWORD] 'password']
    [, user [IDENTIFIED BY [PASSWORD] 'password']] ...
[REQUIRE
  NONE
  | [{SSL | X509}]
  | [CIPHER 'cipher' [AND]]

```

The `GRANT` statement enables system administrators to create MySQL user accounts and to grant rights to from accounts. To use `GRANT`, you must have the `GRANT OPTION` privilege, and you must have the privileges that you are granting. The `REVOKE` statement is related and enables administrators to remove account privileges. See [Section 13.5.1.5, “REVOKE Syntax”](#).

MySQL account information is stored in the tables of the `mysql` database. This database and the access control system are discussed extensively in [Chapter 5, Database Administration](#), which you should consult for additional details.

Important: Some releases of MySQL introduce changes to the structure of the grant tables to add new privileges or features. Whenever you update to a new version of MySQL, you should update your grant tables to make sure that they have the current structure so that you can take advantage of any new capabilities. See [Section 5.6.2, “mysql_upgrade — Check Tables for MySQL Upgrade”](#).

If the grant tables hold privilege rows that contain mixed-case database or table names and the

`lower_case_table_names` system variable is set to a non-zero value, `REVOKE` cannot be used to revoke these privileges. It will be necessary to manipulate the grant tables directly. (`GRANT` will not create such rows when `lower_case_table_names` is set, but such rows might have been created prior to setting the variable.)

Privileges can be granted at several levels:

- **Global level**

Global privileges apply to all databases on a given server. These privileges are stored in the `mysql.user` table. `GRANT ALL ON *.*` and `REVOKE ALL ON *.*` grant and revoke only global privileges.

- **Database level**

Database privileges apply to all objects in a given database. These privileges are stored in the `mysql.db` and `mysql.host` tables. `GRANT ALL ON db_name.*` and `REVOKE ALL ON db_name.*` grant and revoke only database privileges.

- **Table level**

Table privileges apply to all columns in a given table. These privileges are stored in the `mysql.tables_priv` table. `GRANT ALL ON db_name.tbl_name` and `REVOKE ALL ON db_name.tbl_name` grant and revoke only table privileges.

- **Column level**

Column privileges apply to single columns in a given table. These privileges are stored in the `mysql.columns_priv` table. When using `REVOKE`, you must specify the same columns that were granted.

- **Routine level**

The `CREATE ROUTINE`, `ALTER ROUTINE`, `EXECUTE`, and `GRANT` privileges apply to stored routines (functions and procedures). They can be granted at the global and database levels. Also, except for `CREATE ROUTINE`, these privileges can be granted at the routine level for individual routines and are stored in the `mysql.procs_priv` table.

The `object_type` clause should be specified as `TABLE`, `FUNCTION`, or `PROCEDURE` when the following object is a table, a stored function, or a stored procedure.

For the `GRANT` and `REVOKE` statements, `priv_type` can be specified as any of the following:

Privilege	Meaning
<code>ALL [PRIVILEGES]</code>	Sets all simple privileges except <code>GRANT OPTION</code>
<code>ALTER</code>	Enables use of <code>ALTER TABLE</code>
<code>ALTER ROUTINE</code>	Enables stored routines to be altered or dropped
<code>CREATE</code>	Enables use of <code>CREATE TABLE</code>
<code>CREATE ROUTINE</code>	Enables creation of stored routines
<code>CREATE TEMPORARY TABLES</code>	Enables use of <code>CREATE TEMPORARY TABLE</code>
<code>CREATE USER</code>	Enables use of <code>CREATE USER</code> , <code>DROP USER</code> , <code>RENAME USER</code> , and <code>REVOKE ALL PRIVILEGES</code> .
<code>CREATE VIEW</code>	Enables use of <code>CREATE VIEW</code>

DELETE	Enables use of <code>DELETE</code>
DROP	Enables use of <code>DROP TABLE</code>
EVENT	Enables creation of events for the event scheduler
EXECUTE	Enables the user to run stored routines
FILE	Enables use of <code>SELECT ... INTO OUTFILE</code> and <code>LOAD DATA INFILE</code>
INDEX	Enables use of <code>CREATE INDEX</code> and <code>DROP INDEX</code>
INSERT	Enables use of <code>INSERT</code>
LOCK TABLES	Enables use of <code>LOCK TABLES</code> on tables for which you have the <code>SELECT</code> privilege
PROCESS	Enables use of <code>SHOW FULL PROCESSLIST</code>
REFERENCES	Not implemented
RELOAD	Enables use of <code>FLUSH</code>
REPLICATION CLIENT	Enables the user to ask where slave or master servers are
REPLICATION SLAVE	Needed for replication slaves (to read binary log events from the master)
SELECT	Enables use of <code>SELECT</code>
SHOW DATABASES	<code>SHOW DATABASES</code> shows all databases
SHOW VIEW	Enables use of <code>SHOW CREATE VIEW</code>
SHUTDOWN	Enables use of <code>mysqladmin shutdown</code>
SUPER	Enables use of <code>CHANGE MASTER</code> , <code>KILL</code> , <code>PURGE MASTER LOGS</code> , and <code>SET GLOBAL</code> statements, the <code>mysqladmin debug</code> command; allows you to connect (once) even if <code>max_connections</code> is reached
TRIGGER	Enables the user to create or drop triggers
UPDATE	Enables use of <code>UPDATE</code>
USAGE	Synonym for “no privileges”
GRANT OPTION	Enables privileges to be granted

The `EVENT` and `TRIGGER` privileges were added in MySQL 5.1.6. A trigger is associated with a table, so to create or drop a trigger, you must have the `TRIGGER` privilege for the table, not the trigger. (Before MySQL 5.1.6, the `SUPER` privilege was required to create or drop triggers.)

The `REFERENCES` privilege currently is unused.

`USAGE` can be specified when you want to create a user that has no privileges.

Use `SHOW GRANTS` to determine what privileges an account has. See [Section 13.5.4.16](#), “`SHOW GRANTS Syntax`”.

You can assign global privileges by using `ON *.*` syntax or database-level privileges by using `ON db_name.*` syntax. If you specify `ON *` and you have selected a default database, the privileges are granted in that database. (**Warning:** If you specify `ON *` and you have *not* selected a default database, the privileges granted are global.)

The `FILE`, `PROCESS`, `RELOAD`, `REPLICATION CLIENT`, `REPLICATION SLAVE`, `SHOW DATABASES`, `SHUTDOWN`, and `SUPER` privileges are administrative privileges that can only be granted globally (using `ON *.*` syntax).

Other privileges can be granted globally or at more specific levels.

The *priv_type* values that you can specify for a table are `SELECT`, `INSERT`, `UPDATE`, `DELETE`, `CREATE`, `DROP`, `GRANT OPTION`, `INDEX`, `ALTER`, `CREATE VIEW`, `SHOW VIEW` and `TRIGGER`.

The *priv_type* values that you can specify for a column (that is, when you use a *column_list* clause) are `SELECT`, `INSERT`, and `UPDATE`.

The *priv_type* values that you can specify at the routine level are `ALTER ROUTINE`, `EXECUTE`, and `GRANT OPTION`. `CREATE ROUTINE` is not a routine-level privilege because you must have this privilege to create a routine in the first place.

For the global, database, table, and routine levels, `GRANT ALL` assigns only the privileges that exist at the level you are granting. For example, `GRANT ALL ON db_name.*` is a database-level statement, so it does not grant any global-only privileges such as `FILE`.

MySQL allows you to grant privileges even on database objects that do not exist. In such cases, the privileges to be granted must include the `CREATE` privilege. *This behavior is by design*, and is intended to enable the database administrator to prepare user accounts and privileges for database objects that are to be created at a later time.

Important: *MySQL does not automatically revoke any privileges when you drop a table or database.* However, if you drop a routine, any routine-level privileges granted for that routine are revoked.

Note: the `'_'` and `'%'` wildcards are allowed when specifying database names in `GRANT` statements that grant privileges at the global or database levels. This means, for example, that if you want to use a `'_'` character as part of a database name, you should specify it as `'_'` in the `GRANT` statement, to prevent the user from being able to access additional databases matching the wildcard pattern; for example, `GRANT ... ON `foo_bar`.* TO ...`

To accommodate granting rights to users from arbitrary hosts, MySQL supports specifying the *user* value in the form `user_name@host_name`. If a *user_name* or *host_name* value is legal as an unquoted identifier, you need not quote it. However, quotes are necessary to specify a *user_name* string containing special characters (such as `'-'`), or a *host_name* string containing special characters or wildcard characters (such as `'%'`); for example, `'test-user'@'test-hostname'`. Quote the username and hostname separately.

You can specify wildcards in the hostname. For example, `user_name@'%.loc.gov'` applies to *user_name* for any host in the `loc.gov` domain, and `user_name@'144.155.166.%'` applies to *user_name* for any host in the `144.155.166` class C subnet.

The simple form *user_name* is a synonym for `user_name@'%'`.

MySQL does not support wildcards in usernames. Anonymous users are defined by inserting entries with `User=''` into the `mysql.user` table or by creating a user with an empty name with the `GRANT` statement:

```
GRANT ALL ON test.* TO ''@'localhost' ...
```

When specifying quoted values, quote database, table, column, and routine names as identifiers, using backticks (```). Quote hostnames, usernames, and passwords as strings, using single quotes (`'`).

Warning: If you allow anonymous users to connect to the MySQL server, you should also grant privileges to all local users as `user_name@localhost`. Otherwise, the anonymous user account for `localhost` in the `mysql.user` table (created during MySQL installation) is used when named users try to log in to the MySQL server from the local machine. For details, see [Section 5.8.5, “Access Control, Stage 1: Connection Verification”](#).

You can determine whether this applies to you by executing the following query, which lists any anonymous users:

```
SELECT Host, User FROM mysql.user WHERE User='';
```

If you want to delete the local anonymous user account to avoid the problem just described, use these statements:

```
DELETE FROM mysql.user WHERE Host='localhost' AND User='';
FLUSH PRIVILEGES;
```

GRANT supports hostnames up to 60 characters long. Database, table, column, and routine names can be up to 64 characters. Usernames can be up to 16 characters. **Note:** *The allowable length for usernames cannot be changed by altering the `mysql.user` table, and attempting to do so results in unpredictable behavior which may even make it impossible for users to log in to the MySQL server.* You should never alter any of the tables in the `mysql` database in any manner whatsoever except by means of the procedure prescribed by MySQL AB that is described in [Section 5.6.2, “mysql_upgrade — Check Tables for MySQL Upgrade”](#).

The privileges for a table, column, or routine are formed additively as the logical **OR** of the privileges at each of the privilege levels. For example, if the `mysql.user` table specifies that a user has a global **SELECT** privilege, the privilege cannot be denied by an entry at the database, table, or column level.

The privileges for a column can be calculated as follows:

```
global privileges
OR (database privileges AND host privileges)
OR table privileges
OR column privileges
OR routine privileges
```

In most cases, you grant rights to a user at only one of the privilege levels, so life is not normally this complicated. The details of the privilege-checking procedure are presented in [Section 5.8, “The MySQL Access Privilege System”](#).

If you grant privileges for a username/hostname combination that does not exist in the `mysql.user` table, an entry is added and remains there until deleted with a **DELETE** statement. In other words, **GRANT** may create `user` table entries, but **REVOKE** does not remove them; you must do that explicitly using **DROP USER** or **DELETE**.

Warning: If you create a new user but do not specify an **IDENTIFIED BY** clause, the user has no password. This is very insecure. However, you can enable the `NO_AUTO_CREATE_USER` SQL mode to prevent **GRANT** from creating a new user if it would otherwise do so, unless **IDENTIFIED BY** is given to provide the new user a non-empty password.

If a new user is created or if you have global grant privileges, the user's password is set to the password specified by the **IDENTIFIED BY** clause, if one is given. If the user already had a password, this is replaced by the new one.

Passwords can also be set with the **SET PASSWORD** statement. See [Section 13.5.1.6, “SET PASSWORD Syntax”](#).

In the **IDENTIFIED BY** clause, the password should be given as the literal password value. It is unnecessary to use the `PASSWORD()` function as it is for the **SET PASSWORD** statement. For example:

```
GRANT ... IDENTIFIED BY 'mypass';
```

If you do not want to send the password in clear text and you know the hashed value that `PASSWORD()` would return for the password, you can specify the hashed value preceded by the keyword **PASSWORD**:

```
GRANT ...
IDENTIFIED BY PASSWORD '*6C8989366EAF75BB670AD8EA7A7FC1176A95CEF4';
```

In a C program, you can get the hashed value by using the `make_scrambled_password()` C API function.

If you grant privileges for a database, an entry in the `mysql.db` table is created if needed. If all privileges for the database are removed with `REVOKE`, this entry is deleted.

The `SHOW DATABASES` privilege enables the account to see database names by issuing the `SHOW DATABASE` statement. Accounts that do not have this privilege see only databases for which they have some privileges, and cannot use the statement at all if the server was started with the `-skip-show-database` option.

If a user has no privileges for a table, the table name is not displayed when the user requests a list of tables (for example, with a `SHOW TABLES` statement).

The `WITH GRANT OPTION` clause gives the user the ability to give to other users any privileges the user has at the specified privilege level. You should be careful to whom you give the `GRANT OPTION` privilege, because two users with different privileges may be able to join privileges!

You cannot grant another user a privilege which you yourself do not have; the `GRANT OPTION` privilege enables you to assign only those privileges which you yourself possess.

Be aware that when you grant a user the `GRANT OPTION` privilege at a particular privilege level, any privileges the user possesses (or may be given in the future) at that level can also be granted by that user to other users. Suppose that you grant a user the `INSERT` privilege on a database. If you then grant the `SELECT` privilege on the database and specify `WITH GRANT OPTION`, that user can give to other users not only the `SELECT` privilege, but also `INSERT`. If you then grant the `UPDATE` privilege to the user on the database, the user can grant `INSERT`, `SELECT`, and `UPDATE`.

For a non-administrative user, you should not grant the `ALTER` privilege globally or for the `mysql` database. If you do that, the user can try to subvert the privilege system by renaming tables!

The `MAX_QUERIES_PER_HOUR count`, `MAX_UPDATES_PER_HOUR count`, and `MAX_CONNECTIONS_PER_HOUR count` options limit the number of queries, updates, and logins a user can perform during any given one-hour period. If `count` is 0 (the default), this means that there is no limitation for that user.

The `MAX_USER_CONNECTIONS count` option limits the maximum number of simultaneous connections that the account can make. If `count` is 0 (the default), the `max_user_connections` system variable determines the number of simultaneous connections for the account.

Note: To specify any of these resource-limit options for an existing user without affecting existing privileges, use `GRANT USAGE ON *.* ... WITH MAX_...`

See [Section 5.9.4, “Limiting Account Resources”](#).

MySQL can check X509 certificate attributes in addition to the usual authentication that is based on the username and password. To specify SSL-related options for a MySQL account, use the `REQUIRE` clause of the `GRANT` statement. (For background information on the use of SSL with MySQL, see [Section 5.9.7, “Using Secure Connections”](#).)

There are a number of different possibilities for limiting connection types for a given account:

- If the account has no SSL or X509 requirements, unencrypted connections are allowed if the username and password are valid. However, encrypted connections can also be used, at the client's option, if the client has the proper certificate and key files.

- The `REQUIRE SSL` option tells the server to allow only SSL-encrypted connections for the account. Note that this option can be omitted if there are any access-control rows that allow non-SSL connections.

```
GRANT ALL PRIVILEGES ON test.* TO 'root'@'localhost'
  IDENTIFIED BY 'goodsecret' REQUIRE SSL;
```

- `REQUIRE X509` means that the client must have a valid certificate but that the exact certificate, issuer, and subject do not matter. The only requirement is that it should be possible to verify its signature with one of the CA certificates.

```
GRANT ALL PRIVILEGES ON test.* TO 'root'@'localhost'
  IDENTIFIED BY 'goodsecret' REQUIRE X509;
```

- `REQUIRE ISSUER 'issuer'` places the restriction on connection attempts that the client must present a valid X509 certificate issued by CA `'issuer'`. If the client presents a certificate that is valid but has a different issuer, the server rejects the connection. Use of X509 certificates always implies encryption, so the `SSL` option is unnecessary in this case.

```
GRANT ALL PRIVILEGES ON test.* TO 'root'@'localhost'
  IDENTIFIED BY 'goodsecret'
  REQUIRE ISSUER '/C=FI/ST=Some-State/L=Helsinki/
  O=MySQL Finland AB/CN=Tonu Samuel/Email=tonu@example.com';
```

Note that the `'issuer'` value should be entered as a single string.

- `REQUIRE SUBJECT 'subject'` places the restriction on connection attempts that the client must present a valid X509 certificate containing the subject `subject`. If the client presents a certificate that is valid but has a different subject, the server rejects the connection.

```
GRANT ALL PRIVILEGES ON test.* TO 'root'@'localhost'
  IDENTIFIED BY 'goodsecret'
  REQUIRE SUBJECT '/C=EE/ST=Some-State/L=Tallinn/
  O=MySQL demo client certificate/
  CN=Tonu Samuel/Email=tonu@example.com';
```

Note that the `'subject'` value should be entered as a single string.

- `REQUIRE CIPHER 'cipher'` is needed to ensure that ciphers and key lengths of sufficient strength are used. SSL itself can be weak if old algorithms using short encryption keys are used. Using this option, you can ask that a specific cipher method is used to allow a connection.

```
GRANT ALL PRIVILEGES ON test.* TO 'root'@'localhost'
  IDENTIFIED BY 'goodsecret'
  REQUIRE CIPHER 'EDH-RSA-DES-CBC3-SHA';
```

The `SUBJECT`, `ISSUER`, and `CIPHER` options can be combined in the `REQUIRE` clause like this:

```
GRANT ALL PRIVILEGES ON test.* TO 'root'@'localhost'
  IDENTIFIED BY 'goodsecret'
  REQUIRE SUBJECT '/C=EE/ST=Some-State/L=Tallinn/
  O=MySQL demo client certificate/
  CN=Tonu Samuel/Email=tonu@example.com'
  AND ISSUER '/C=FI/ST=Some-State/L=Helsinki/
  O=MySQL Finland AB/CN=Tonu Samuel/Email=tonu@example.com'
  AND CIPHER 'EDH-RSA-DES-CBC3-SHA';
```

The `AND` keyword is optional between `REQUIRE` options.

The order of the options does not matter, but no option can be specified twice.

When `mysqld` starts, all privileges are read into memory. For details, see [Section 5.8.7, “When Privilege Changes Take Effect”](#).

Note that if you are using table, column, or routine privileges for even one user, the server examines table, column, and routine privileges for all users and this slows down MySQL a bit. Similarly, if you limit the number of queries, updates, or connections for any users, the server must monitor these values.

The biggest differences between the standard SQL and MySQL versions of `GRANT` are:

- In MySQL, privileges are associated with the combination of a hostname and username and not with only a username.
- Standard SQL does not have global or database-level privileges, nor does it support all the privilege types that MySQL supports.
- MySQL does not support the standard SQL `UNDER` privilege.
- Standard SQL privileges are structured in a hierarchical manner. If you remove a user, all privileges the user has been granted are revoked. This is also true in MySQL if you use `DROP USER`. See [Section 13.5.1.2, “DROP USER Syntax”](#).
- In standard SQL, when you drop a table, all privileges for the table are revoked. In standard SQL, when you revoke a privilege, all privileges that were granted based on that privilege are also revoked. In MySQL, privileges can be dropped only with explicit `REVOKE` statements or by manipulating values stored in the MySQL grant tables.
- In MySQL, it is possible to have the `INSERT` privilege for only some of the columns in a table. In this case, you can still execute `INSERT` statements on the table, provided that you omit those columns for which you do not have the `INSERT` privilege. The omitted columns are set to their implicit default values if strict SQL mode is not enabled. In strict mode, the statement is rejected if any of the omitted columns have no default value. (Standard SQL requires you to have the `INSERT` privilege on all columns.) [Section 5.2.6, “SQL Modes”](#), discusses strict mode. [Section 11.1.4, “Data Type Default Values”](#), discusses implicit default values.

13.5.1.4. RENAME USER Syntax

```
RENAME USER old_user TO new_user
[, old_user TO new_user] ...
```

The `RENAME USER` statement renames existing MySQL accounts. To use it, you must have the global `CREATE USER` privilege or the `UPDATE` privilege for the `mysql` database. An error occurs if any old account does not exist or any new account exists. Each account is named using the same format as for the `GRANT` statement; for example, `'jeffrey'@'localhost'`. The user and host parts of the account name correspond to the `User` and `Host` column values of the `user` table row for the account.

13.5.1.5. REVOKE Syntax

```
REVOKE priv_type [(column_list)] [, priv_type [(column_list))] ...
ON [object_type] {tbl_name | * | *.* | db_name.*}
FROM user [, user] ...

REVOKE ALL PRIVILEGES, GRANT OPTION FROM user [, user] ...
```

The `REVOKE` statement enables system administrators to revoke privileges from MySQL accounts. To use `REVOKE`, you must have the `GRANT OPTION` privilege, and you must have the privileges that you are revoking.

For details on the levels at which privileges exist, the allowable *priv_type* values, and the syntax for specifying users and passwords, see [Section 13.5.1.3, “GRANT Syntax”](#)

If the grant tables hold privilege rows that contain mixed-case database or table names and the `lower_case_table_names` system variable is set to a non-zero value, `REVOKE` cannot be used to revoke these privileges. It will be necessary to manipulate the grant tables directly. (`GRANT` will not create such rows when `lower_case_table_names` is set, but such rows might have been created prior to setting the variable.)

To revoke all privileges, use the following syntax, which drops all global, database-, table-, and column-level privileges for the named user or users:

```
REVOKE ALL PRIVILEGES, GRANT OPTION FROM user [, user] ...
```

To use this `REVOKE` syntax, you must have the global `CREATE USER` privilege or the `UPDATE` privilege for the `mysql` database.

`REVOKE` removes privileges, but does not drop `user` table entries. You must do that explicitly using `DROP USER` or `DELETE`.

13.5.1.6. SET PASSWORD Syntax

```
SET PASSWORD [FOR user] = PASSWORD('some password')
```

The `SET PASSWORD` statement assigns a password to an existing MySQL user account.

With no `FOR` clause, this statement sets the password for the current user. Any client that has connected to the server using a non-anonymous account can change the password for that account.

With a `FOR` clause, this statement sets the password for a specific account on the current server host. Only clients that have the `UPDATE` privilege for the `mysql` database can do this. The `user` value should be given in `user_name@host_name` format, where `user_name` and `host_name` are exactly as they are listed in the `User` and `Host` columns of the `mysql.user` table entry. For example, if you had an entry with `User` and `Host` column values of `'bob'` and `'%.loc.gov'`, you would write the statement like this:

```
SET PASSWORD FOR 'bob'@'%.loc.gov' = PASSWORD('newpass');
```

That is equivalent to the following statements:

```
UPDATE mysql.user SET Password=PASSWORD('newpass')
  WHERE User='bob' AND Host='%.loc.gov';
FLUSH PRIVILEGES;
```

Note: If you are connecting to a MySQL 4.1 or later server using a pre-4.1 client program, do not use the preceding `SET PASSWORD` or `UPDATE` statement without reading [Section 5.8.9, “Password Hashing as of MySQL 4.1”](#), first. The password format changed in MySQL 4.1, and under certain circumstances it is possible that if you change your password, you might not be able to connect to the server afterward.

You can see which account the server authenticated you as by executing `SELECT CURRENT_USER()`.

13.5.2. Table Maintenance Statements

13.5.2.1. ANALYZE TABLE Syntax

```
ANALYZE [LOCAL | NO_WRITE_TO_BINLOG] TABLE tbl_name [, tbl_name] ...
```

`ANALYZE TABLE` analyzes and stores the key distribution for a table. During the analysis, the table is locked with a read lock for `MyISAM`. For `InnoDB` the table is locked with a write lock. This statement works with `MyISAM`, and `InnoDB` tables. For `MyISAM` tables, this statement is equivalent to using `myisamchk --analyze`.

For more information on how the analysis works within `InnoDB`, see [Section 14.5.16, “Restrictions on InnoDB Tables”](#).

MySQL uses the stored key distribution to decide the order in which tables should be joined when you perform a join on something other than a constant.

This statement requires `SELECT` and `INSERT` privileges for the table.

`ANALYZE TABLE` returns a result set with the following columns:

Column	Value
Table	The table name
Op	Always <code>analyze</code>
Msg_type	One of <code>status</code> , <code>error</code> , <code>info</code> , or <code>warning</code>
Msg_text	The message

You can check the stored key distribution with the `SHOW INDEX` statement. See [Section 13.5.4.17, “SHOW INDEX Syntax”](#).

If the table has not changed since the last `ANALYZE TABLE` statement, the table is not analyzed again.

`ANALYZE TABLE` statements are written to the binary log unless the optional `NO_WRITE_TO_BINLOG` keyword (or its alias `LOCAL`) is used. This is done so that `ANALYZE TABLE` statements used on a MySQL server acting as a replication master will be replicated by default to the replication slave.

13.5.2.2. BACKUP TABLE Syntax

```
BACKUP TABLE tbl_name [, tbl_name] ... TO '/path/to/backup/directory'
```

Note: This statement is deprecated. We are working on a better replacement for it that will provide on-line backup capabilities. In the meantime, the `mysqlhotcopy` script can be used instead.

`BACKUP TABLE` copies to the backup directory the minimum number of table files needed to restore the table, after flushing any buffered changes to disk. The statement works only for `MyISAM` tables. It copies the `.frm` definition and `.MYD` data files. The `.MYI` index file can be rebuilt from those two files. The directory should be specified as a full pathname. To restore the table, use `RESTORE TABLE`.

During the backup, a read lock is held for each table, one at a time, as they are being backed up. If you want to back up several tables as a snapshot (preventing any of them from being changed during the backup operation), issue a `LOCK TABLES` statement first, to obtain a read lock for all tables in the group.

`BACKUP TABLE` returns a result set with the following columns:

Column	Value
Table	The table name

Op	Always <code>backup</code>
Msg_type	One of <code>status</code> , <code>error</code> , <code>info</code> , or <code>warning</code>
Msg_text	The message

13.5.2.3. CHECK TABLE Syntax

```
CHECK TABLE tbl_name [, tbl_name] ... [option] ...
option = {FOR UPGRADE | QUICK | FAST | MEDIUM | EXTENDED | CHANGED}
```

`CHECK TABLE` checks a table or tables for errors. `CHECK TABLE` works for `MyISAM`, `InnoDB`, and `ARCHIVE` tables. Starting with MySQL 5.1.9, `CHECK` is also valid for `CSV` tables, see [Section 14.11, “The CSV Storage Engine”](#). For `MyISAM` tables, the key statistics are updated as well.

`CHECK TABLE` can also check views for problems, such as tables that are referenced in the view definition that no longer exist.

`CHECK TABLE` returns a result set with the following columns:

Column	Value
Table	The table name
Op	Always <code>check</code>
Msg_type	One of <code>status</code> , <code>error</code> , <code>info</code> , or <code>warning</code>
Msg_text	The message

Note that the statement might produce many rows of information for each checked table. The last row has a `Msg_type` value of `status` and the `Msg_text` normally should be `OK`. If you don't get `OK`, or `Table is already up to date` you should normally run a repair of the table. See [Section 5.10.4, “Table Maintenance and Crash Recovery”](#). `Table is already up to date` means that the storage engine for the table indicated that there was no need to check the table.

The `FOR UPGRADE` option checks whether the named tables are compatible with the current version of MySQL. This option was added in MySQL 5.1.7. With `FOR UPGRADE`, the server checks each table to determine whether there have been any incompatible changes in any of the table's data types or indexes since the table was created. If not, the check succeeds. Otherwise, if there is a possible incompatibility, the server runs a full check on the table (which might take some time). If the full check succeeds, the server marks the table's `.frm` file with the current MySQL version number. Marking the `.frm` file ensures that further checks for the table with the same version of the server will be fast.

Incompatibilities might occur because the storage format for a data type has changed or because its sort order has changed. Our aim is to avoid these changes, but occasionally they are necessary to correct problems that would be worse than an incompatibility between releases.

Currently, `FOR UPGRADE` discovers these incompatibilities:

- The indexing order for end-space in `TEXT` columns for `InnoDB` and `MyISAM` tables changed between MySQL 4.1 and 5.0.
- The storage method of the new `DECIMAL` data type changed between MySQL 5.0.3 and 5.0.5.

The other check options that can be given are shown in the following table. These options apply only to

checking `MyISAM` tables and are ignored for `InnoDB` tables and views.

Type	Meaning
<code>QUICK</code>	Do not scan the rows to check for incorrect links.
<code>FAST</code>	Check only tables that have not been closed properly.
<code>CHANGED</code>	Check only tables that have been changed since the last check or that have not been closed properly.
<code>MEDIUM</code>	Scan rows to verify that deleted links are valid. This also calculates a key checksum for the rows and verifies this with a calculated checksum for the keys.
<code>EXTENDED</code>	Do a full key lookup for all keys for each row. This ensures that the table is 100% consistent, but takes a long time.

If none of the options `QUICK`, `MEDIUM`, or `EXTENDED` are specified, the default check type for dynamic-format `MyISAM` tables is `MEDIUM`. This has the same result as running `myisamchk -medium-check tbl_name` on the table. The default check type also is `MEDIUM` for static-format `MyISAM` tables, unless `CHANGED` or `FAST` is specified. In that case, the default is `QUICK`. The row scan is skipped for `CHANGED` and `FAST` because the rows are very seldom corrupted.

You can combine check options, as in the following example that does a quick check on the table to determine whether it was closed properly:

```
CHECK TABLE test_table FAST QUICK;
```

Note: In some cases, `CHECK TABLE` changes the table. This happens if the table is marked as “corrupted” or “not closed properly” but `CHECK TABLE` does not find any problems in the table. In this case, `CHECK TABLE` marks the table as okay.

If a table is corrupted, it is most likely that the problem is in the indexes and not in the data part. All of the preceding check types check the indexes thoroughly and should thus find most errors.

If you just want to check a table that you assume is okay, you should use no check options or the `QUICK` option. The latter should be used when you are in a hurry and can take the very small risk that `QUICK` does not find an error in the data file. (In most cases, under normal usage, MySQL should find any error in the data file. If this happens, the table is marked as “corrupted” and cannot be used until it is repaired.)

`FAST` and `CHANGED` are mostly intended to be used from a script (for example, to be executed from `cron`) if you want to check tables from time to time. In most cases, `FAST` is to be preferred over `CHANGED`. (The only case when it is not preferred is when you suspect that you have found a bug in the `MyISAM` code.)

`EXTENDED` is to be used only after you have run a normal check but still get strange errors from a table when MySQL tries to update a row or find a row by key. This is very unlikely if a normal check has succeeded.

Some problems reported by `CHECK TABLE` cannot be corrected automatically:

- Found row where the `auto_increment` column has the value 0.

This means that you have a row in the table where the `AUTO_INCREMENT` index column contains the value 0. (It is possible to create a row where the `AUTO_INCREMENT` column is 0 by explicitly setting the column to 0 with an `UPDATE` statement.)

This is not an error in itself, but could cause trouble if you decide to dump the table and restore it or

do an `ALTER TABLE` on the table. In this case, the `AUTO_INCREMENT` column changes value according to the rules of `AUTO_INCREMENT` columns, which could cause problems such as a duplicate-key error.

To get rid of the warning, simply execute an `UPDATE` statement to set the column to some value other than 0.

13.5.2.4. CHECKSUM TABLE Syntax

```
CHECKSUM TABLE tbl_name [, tbl_name] ... [ QUICK | EXTENDED ]
```

`CHECKSUM TABLE` reports a table checksum.

With `QUICK`, the live table checksum is reported if it is available, or `NULL` otherwise. This is very fast. A live checksum is enabled by specifying the `CHECKSUM=1` table option when you create the table; currently, this is supported only for `MyISAM` tables. See [Section 13.1.7, “CREATE TABLE Syntax”](#).

With `EXTENDED`, the entire table is read row by row and the checksum is calculated. This can be very slow for large tables.

If neither `QUICK` nor `EXTENDED` is specified, MySQL returns a live checksum if the table storage engine supports it and scans the table otherwise.

For a non-existent table, `CHECKSUM TABLE` returns `NULL` and generates a warning.

13.5.2.5. OPTIMIZE TABLE Syntax

```
OPTIMIZE [LOCAL | NO_WRITE_TO_BINLOG] TABLE tbl_name [, tbl_name] ...
```

`OPTIMIZE TABLE` should be used if you have deleted a large part of a table or if you have made many changes to a table with variable-length rows (tables that have `VARCHAR`, `VARBINARY`, `BLOB`, or `TEXT` columns). Deleted rows are maintained in a linked list and subsequent `INSERT` operations reuse old row positions. You can use `OPTIMIZE TABLE` to reclaim the unused space and to defragment the data file.

This statement requires `SELECT` and `INSERT` privileges for the table.

In most setups, you need not run `OPTIMIZE TABLE` at all. Even if you do a lot of updates to variable-length rows, it is not likely that you need to do this more than once a week or month and only on certain tables.

`OPTIMIZE TABLE` works only for `MyISAM`, and `InnoDB` tables.

For `MyISAM` tables, `OPTIMIZE TABLE` works as follows:

1. If the table has deleted or split rows, repair the table.
2. If the index pages are not sorted, sort them.
3. If the table's statistics are not up to date (and the repair could not be accomplished by sorting the index), update them.

For `InnoDB` tables, `OPTIMIZE TABLE` is mapped to `ALTER TABLE`, which rebuilds the table to update index statistics and free unused space in the clustered index.

You can make `OPTIMIZE TABLE` work on other storage engines by starting `mysqld` with the `--skip-new` or `--safe-mode` option. In this case, `OPTIMIZE TABLE` is just mapped to `ALTER TABLE`.

`OPTIMIZE TABLE` returns a result set with the following columns:

Column	Value
Table	The table name
Op	Always <code>optimize</code>
Msg_type	One of <code>status</code> , <code>error</code> , <code>info</code> , or <code>warning</code>
Msg_text	The message

Note that MySQL locks the table during the time `OPTIMIZE TABLE` is running.

`OPTIMIZE TABLE` statements are written to the binary log unless the optional `NO_WRITE_TO_BINLOG` keyword (or its alias `LOCAL`) is used. This is done so that `OPTIMIZE TABLE` statements used on a MySQL server acting as a replication master will be replicated by default to the replication slave.

13.5.2.6. REPAIR TABLE Syntax

```
REPAIR [LOCAL | NO_WRITE_TO_BINLOG] TABLE
      tbl_name [, tbl_name] ... [QUICK] [EXTENDED] [USE_FRM]
```

`REPAIR TABLE` repairs a possibly corrupted table. By default, it has the same effect as `myisamchk --recover tbl_name`. `REPAIR TABLE` works for `MyISAM` and for `ARCHIVE` tables. Starting with MySQL 5.1.9, `REPAIR` is also valid for `CSV` tables. See Section 14.4, “The `MyISAM` Storage Engine”, and Section 14.10, “The `ARCHIVE` Storage Engine”, and Section 14.11, “The `CSV` Storage Engine”

This statement requires `SELECT` and `INSERT` privileges for the table.

Normally, you should never have to run this statement. However, if disaster strikes, `REPAIR TABLE` is very likely to get back all your data from a `MyISAM` table. If your tables become corrupted often, you should try to find the reason for it, to eliminate the need to use `REPAIR TABLE`. See Section A.4.2, “What to Do If MySQL Keeps Crashing”, and Section 14.4.4, “`MyISAM` Table Problems”.

Warning: If the server dies during a `REPAIR TABLE` operation, it is essential after restarting it that you immediately execute another `REPAIR TABLE` statement for the table before performing any other operations on it. (It is always a good idea to start by making a backup.) In the worst case, you might have a new clean index file without information about the data file, and then the next operation you perform could overwrite the data file. This is an unlikely but possible scenario.

`REPAIR TABLE` returns a result set with the following columns:

Column	Value
Table	The table name
Op	Always <code>repair</code>
Msg_type	One of <code>status</code> , <code>error</code> , <code>info</code> , or <code>warning</code>
Msg_text	The message

The `REPAIR TABLE` statement might produce many rows of information for each repaired table. The

last row has a `Msg_type` value of `status` and `Msg_text` normally should be `OK`. If you do not get `OK`, you should try repairing the table with `myisamchk --safe-recover`. (`REPAIR TABLE` does not yet implement all the options of `myisamchk`.) With `myisamchk --safe-recover`, you can also use options that `REPAIR TABLE` does not support, such as `--max-record-length`.

If `QUICK` is given, `REPAIR TABLE` tries to repair only the index tree. This type of repair is like that done by `myisamchk --recover --quick`.

If you use `EXTENDED`, MySQL creates the index row by row instead of creating one index at a time with sorting. This type of repair is like that done by `myisamchk --safe-recover`.

There is also a `USE_FRM` mode available for `REPAIR TABLE`. Use this if the `.MYI` index file is missing or if its header is corrupted. In this mode, MySQL re-creates the `.MYI` file using information from the `.frm` file. This kind of repair cannot be done with `myisamchk`. **Note:** Use this mode *only* if you cannot use regular `REPAIR` modes. The `.MYI` header contains important table metadata (in particular, current `AUTO_INCREMENT` value and `Delete link`) that are lost in `REPAIR ... USE_FRM`. Don't use `USE_FRM` if the table is compressed because this information is also stored in the `.MYI` file.

`REPAIR TABLE` statements are written to the binary log unless the optional `NO_WRITE_TO_BINLOG` keyword (or its alias `LOCAL`) is used. This is done so that `REPAIR TABLE` statements used on a MySQL server acting as a replication master will be replicated by default to the replication slave.

13.5.2.7. RESTORE TABLE Syntax

```
RESTORE TABLE tbl_name [, tbl_name] ... FROM '/path/to/backup/directory'
```

`RESTORE TABLE` restores the table or tables from a backup that was made with `BACKUP TABLE`. The directory should be specified as a full pathname.

Existing tables are not overwritten; if you try to restore over an existing table, an error occurs. Just as for `BACKUP TABLE`, `RESTORE TABLE` currently works only for `MyISAM` tables. Restored tables are not replicated from master to slave.

The backup for each table consists of its `.frm` format file and `.MYD` data file. The restore operation restores those files, and then uses them to rebuild the `.MYI` index file. Restoring takes longer than backing up due to the need to rebuild the indexes. The more indexes the table has, the longer it takes.

`RESTORE TABLE` returns a result set with the following columns:

Column	Value
<code>Table</code>	The table name
<code>Op</code>	Always <code>restore</code>
<code>Msg_type</code>	One of <code>status</code> , <code>error</code> , <code>info</code> , or <code>warning</code>
<code>Msg_text</code>	The message

13.5.3. SET Syntax

```
SET variable_assignment [, variable_assignment] ...

variable_assignment:
  user_var_name = expr
  | [GLOBAL | SESSION] system_var_name = expr
  | [@@global. | @@session. | @@] system_var_name = expr
```

The `SET` statement assigns values to different types of variables that affect the operation of the server or your client. Older versions of MySQL employed `SET OPTION`, but this syntax is deprecated in favor

of `SET` without `OPTION`.

This section describes use of `SET` for assigning values to system variables or user variables. For general information about these types of variables, see [Section 5.2.3, “System Variables”](#), and [Section 9.3, “User-Defined Variables”](#). System variables also can be set at server startup, as described in [Section 5.2.4, “Using System Variables”](#).

Some variants of `SET` syntax are used in other contexts:

- `SET PASSWORD` assigns account passwords. See [Section 13.5.1.6, “SET PASSWORD Syntax”](#).
- `SET TRANSACTION ISOLATION LEVEL` sets the isolation level for transaction processing. See [Section 13.4.6, “SET TRANSACTION Syntax”](#).
- `SET` is used within stored routines to assign values to local routine variables. See [Section 18.2.7.2, “Variable SET Statement”](#).

The following discussion shows the different `SET` syntaxes that you can use to set variables. The examples use the `=` assignment operator, but the `:=` operator also is allowable.

A user variable is written as `@var_name` and can be set as follows:

```
SET @var_name = expr;
```

Many system variables are dynamic and can be changed while the server runs by using the `SET` statement. For a list, see [Section 5.2.4.2, “Dynamic System Variables”](#). To change a system variable with `SET`, refer to it as `var_name`, optionally preceded by a modifier:

- To indicate explicitly that a variable is a global variable, precede its name by `GLOBAL` or `@@global..` The `SUPER` privilege is required to set global variables.
- To indicate explicitly that a variable is a session variable, precede its name by `SESSION`, `@@session.`, or `@@`. Setting a session variable requires no special privilege, but a client can change only its own session variables, not those of any other client.
- `LOCAL` and `@@local.` are synonyms for `SESSION` and `@@session..`
- If no modifier is present, `SET` changes the session variable.

A `SET` statement can contain multiple variable assignments, separated by commas. If you set several system variables, the most recent `GLOBAL` or `SESSION` modifier in the statement is used for following variables that have no modifier specified.

Examples:

```
SET sort_buffer_size=10000;
SET @@local.sort_buffer_size=10000;
SET GLOBAL sort_buffer_size=1000000, SESSION sort_buffer_size=1000000;
SET @@sort_buffer_size=1000000;
SET @@global.sort_buffer_size=1000000, @@local.sort_buffer_size=1000000;
```

When you assign a value to a system variable with `SET`, you cannot use suffix letters in the value (as can be done with startup options). However, the value can take the form of an expression:

```
SET sort_buffer_size = 10 * 1024 * 1024;
```

The `@@var_name` syntax for system variables is supported for compatibility with some other database systems.

If you change a session system variable, the value remains in effect until your session ends or until you change the variable to a different value. The change is not visible to other clients.

If you change a global system variable, the value is remembered and used for new connections until the server restarts. (To make a global system variable setting permanent, you should set it in an option file.) The change is visible to any client that accesses that global variable. However, the change affects the corresponding session variable only for clients that connect after the change. The global variable change does not affect the session variable for any client that is currently connected (not even that of the client that issues the `SET GLOBAL` statement).

To prevent incorrect usage, MySQL produces an error if you use `SET GLOBAL` with a variable that can only be used with `SET SESSION` or if you do not specify `GLOBAL` (or `@@global.`) when setting a global variable.

To set a `SESSION` variable to the `GLOBAL` value or a `GLOBAL` value to the compiled-in MySQL default value, use the `DEFAULT` keyword. For example, the following two statements are identical in setting the session value of `max_join_size` to the global value:

```
SET max_join_size=DEFAULT;
SET @@session.max_join_size=@@global.max_join_size;
```

Not all system variables can be set to `DEFAULT`. In such cases, use of `DEFAULT` results in an error.

You can refer to the values of specific global or session system variables in expressions by using one of the `@@`-modifiers. For example, you can retrieve values in a `SELECT` statement like this:

```
SELECT @@global.sql_mode, @@session.sql_mode, @@sql_mode;
```

When you refer to a system variable in an expression as `@@var_name` (that is, when you do not specify `@@global.` or `@@session.`), MySQL returns the session value if it exists and the global value otherwise. (This differs from `SET @@var_name = value`, which always refers to the session value.)

To display system variables names and values, use the `SHOW VARIABLES` statement. (See [Section 13.5.4.29](#), “`SHOW VARIABLES Syntax`”.)

The following list describes options that have non-standard syntax or that are not described in the list of system variables found in [Section 5.2.3](#), “`System Variables`”. Although the options described here are not displayed by `SHOW VARIABLES`, you can obtain their values with `SELECT` (with the exception of `CHARACTER SET` and `SET NAMES`). For example:

```
mysql> SELECT @@AUTOCOMMIT;
+-----+
| @@AUTOCOMMIT |
+-----+
|             1 |
+-----+
```

The lettercase of these options does not matter.

- `AUTOCOMMIT = {0 | 1}`

Set the autocommit mode. If set to 1, all changes to a table take effect immediately. If set to 0 you have to use `COMMIT` to accept a transaction or `ROLLBACK` to cancel it. By default, client connections begin with `AUTOCOMMIT` set to 1. If you change `AUTOCOMMIT` mode from 0 to 1, MySQL performs an automatic `COMMIT` of any open transaction. Another way to begin a transaction is to

use a `START TRANSACTION` or `BEGIN` statement. See [Section 13.4.1, “START TRANSACTION, COMMIT, and ROLLBACK Syntax”](#).

- `BIG_TABLES = {0 | 1}`

If set to 1, all temporary tables are stored on disk rather than in memory. This is a little slower, but the error `The table tbl_name is full` does not occur for `SELECT` operations that require a large temporary table. The default value for a new connection is 0 (use in-memory temporary tables). Normally, you should never need to set this variable, because in-memory tables are automatically converted to disk-based tables as required. (**Note:** This variable was formerly named `SQL_BIG_TABLES`.)

- `CHARACTER SET {charset_name | DEFAULT}`

This maps all strings from and to the client with the given mapping. You can add new mappings by editing `sql/convert.cc` in the MySQL source distribution. `SET CHARACTER SET` sets three session system variables: `character_set_client` and `character_set_results` are set to the given character set, and `character_set_connection` to the value of `character_set_database`. See [Section 10.4, “Connection Character Sets and Collations”](#).

The default mapping can be restored by using the value `DEFAULT`. The default depends on the server configuration.

Note that the syntax for `SET CHARACTER SET` differs from that for setting most other options.

- `FOREIGN_KEY_CHECKS = {0 | 1}`

If set to 1 (the default), foreign key constraints for `InnoDB` tables are checked. If set to 0, they are ignored. Disabling foreign key checking can be useful for reloading `InnoDB` tables in an order different from that required by their parent/child relationships. See [Section 14.5.6.4, “FOREIGN KEY Constraints”](#).

- `IDENTITY = value`

This variable is a synonym for the `LAST_INSERT_ID` variable. It exists for compatibility with other database systems. You can read its value with `SELECT @@IDENTITY`, and set it using `SET IDENTITY`.

- `INSERT_ID = value`

Set the value to be used by the following `INSERT` or `ALTER TABLE` statement when inserting an `AUTO_INCREMENT` value. This is mainly used with the binary log.

- `LAST_INSERT_ID = value`

Set the value to be returned from `LAST_INSERT_ID()`. This is stored in the binary log when you use `LAST_INSERT_ID()` in a statement that updates a table. Setting this variable does not update the value returned by the `mysql_insert_id()` C API function.

- `NAMES {'charset_name' [COLLATE 'collation_name']} | DEFAULT}`

`SET NAMES` sets the three session system variables `character_set_client`, `character_set_connection`, and `character_set_results` to the given character set. Setting `character_set_connection` to `charset_name` also sets `collation_connection` to the default collation for `charset_name`. The optional `COLLATE` clause may be used to specify a collation explicitly. See [Section 10.4, “Connection Character Sets and Collations”](#).

The default mapping can be restored by using a value of `DEFAULT`. The default depends on the server configuration.

Note that the syntax for `SET NAMES` differs from that for setting most other options.

- `ONE_SHOT`

This option is a modifier, not a variable. It can be used to influence the effect of variables that set the character set, the collation, and the time zone. `ONE_SHOT` is primarily used for replication purposes: `mysqlbinlog` uses `SET ONE_SHOT` to modify temporarily the values of character set, collation, and time zone variables to reflect at rollforward what they were originally.

You cannot use `ONE_SHOT` with other than the allowed set of variables; if you try, you get an error like this:

```
mysql> SET ONE_SHOT max_allowed_packet = 1;
ERROR 1382 (HY000): The 'SET ONE_SHOT' syntax is reserved for purposes
internal to the MySQL server
```

If `ONE_SHOT` is used with the allowed variables, it changes the variables as requested, but only for the next non-`SET` statement. After that, the server resets all character set, collation, and time zone-related system variables to their previous values. Example:

```
mysql> SET ONE_SHOT character_set_connection = latin5;
mysql> SET ONE_SHOT collation_connection = latin5_turkish_ci;
mysql> SHOW VARIABLES LIKE '%_connection';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| character_set_connection | latin5 |
| collation_connection | latin5_turkish_ci |
+-----+-----+

mysql> SHOW VARIABLES LIKE '%_connection';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| character_set_connection | latin1 |
| collation_connection | latin1_swedish_ci |
+-----+-----+
```

- `SQL_AUTO_IS_NULL = {0 | 1}`

If set to 1 (the default), you can find the last inserted row for a table that contains an `AUTO_INCREMENT` column by using the following construct:

```
WHERE auto_increment_column IS NULL
```

This behavior is used by some ODBC programs, such as Access.

- `SQL_BIG_SELECTS = {0 | 1}`

If set to 0, MySQL aborts `SELECT` statements that are likely to take a very long time to execute (that is, statements for which the optimizer estimates that the number of examined rows exceeds the value of `max_join_size`). This is useful when an inadvisable `WHERE` statement has been issued. The default value for a new connection is 1, which allows all `SELECT` statements.

If you set the `max_join_size` system variable to a value other than `DEFAULT`, `SQL_BIG_SELECTS` is set to 0.

- `SQL_BUFFER_RESULT = {0 | 1}`

If set to 1, `SQL_BUFFER_RESULT` forces results from `SELECT` statements to be put into temporary

tables. This helps MySQL free the table locks early and can be beneficial in cases where it takes a long time to send results to the client. The default value is 0.

- `SQL_LOG_BIN = {0 | 1}`

If set to 0, no logging is done to the binary log for the client. The client must have the `SUPER` privilege to set this option. The default value is 1.

- `SQL_LOG_OFF = {0 | 1}`

If set to 1, no logging is done to the general query log for this client. The client must have the `SUPER` privilege to set this option. The default value is 0.

- `SQL_LOG_UPDATE = {0 | 1}`

This variable is deprecated, and is mapped to `SQL_LOG_BIN`.

- `SQL_NOTES = {0 | 1}`

If set to 1 (the default), warnings of `Note` level are recorded. If set to 0, `Note` warnings are suppressed. `mysqldump` includes output to set this variable to 0 so that reloading the dump file does not produce warnings for events that do not affect the integrity of the reload operation.

- `SQL_QUOTE_SHOW_CREATE = {0 | 1}`

If set to 1 (the default), the server quotes identifiers for `SHOW CREATE TABLE` and `SHOW CREATE DATABASE` statements. If set to 0, quoting is disabled. This option is enabled by default so that replication works for identifiers that require quoting. See [Section 13.5.4.9, “SHOW CREATE TABLE Syntax”](#), and [Section 13.5.4.6, “SHOW CREATE DATABASE Syntax”](#).

- `SQL_SAFE_UPDATES = {0 | 1}`

If set to 1, MySQL aborts `UPDATE` or `DELETE` statements that do not use a key in the `WHERE` clause or a `LIMIT` clause. This makes it possible to catch `UPDATE` or `DELETE` statements where keys are not used properly and that would probably change or delete a large number of rows. The default value is 0.

- `SQL_SELECT_LIMIT = {value | DEFAULT}`

The maximum number of rows to return from `SELECT` statements. The default value for a new connection is “unlimited.” If you have changed the limit, the default value can be restored by using a `SQL_SELECT_LIMIT` value of `DEFAULT`.

If a `SELECT` has a `LIMIT` clause, the `LIMIT` takes precedence over the value of `SQL_SELECT_LIMIT`.

`SQL_SELECT_LIMIT` does not apply to `SELECT` statements executed within stored routines. It also does not apply to `SELECT` statements that do not produce a result set to be returned to the client. These include `SELECT` statements in subqueries, `CREATE TABLE ... SELECT`, and `INSERT INTO ... SELECT`.

- `SQL_WARNINGS = {0 | 1}`

This variable controls whether single-row `INSERT` statements produce an information string if warnings occur. The default is 0. Set the value to 1 to produce an information string.

- `TIMESTAMP = {timestamp_value | DEFAULT}`

Set the time for this client. This is used to get the original timestamp if you use the binary log to re-

store rows. `timestamp_value` should be a Unix epoch timestamp, not a MySQL timestamp.

`SET TIMESTAMP` affects the value returned by `NOW()` but not by `SYSDATE()`. This means that timestamp settings in the binary log have no effect on invocations of `SYSDATE()`. The server can be started with the `--sysdate-is-now` option to cause `SYSDATE()` to be an alias for `NOW()`, in which case `SET TIMESTAMP` affects both functions.

- `UNIQUE_CHECKS = {0 | 1}`

If set to 1 (the default), uniqueness checks for secondary indexes in `InnoDB` tables are performed. If set to 0, storage engines are allowed to assume that duplicate keys are not present in input data. If you know for certain that your data does not contain uniqueness violations, you can set this to 0 to speed up large table imports to `InnoDB`.

Note that setting this variable to 0 does not *require* storage engines to ignore duplicate keys. An engine is still allowed to check for them and issue duplicate-key errors if it detects them.

13.5.4. SHOW Syntax

`SHOW` has many forms that provide information about databases, tables, columns, or status information about the server. This section describes those following:

```
SHOW AUTHORS
SHOW CHARACTER SET [LIKE 'pattern']
SHOW COLLATION [LIKE 'pattern']
SHOW [FULL] COLUMNS FROM tbl_name [FROM db_name] [LIKE 'pattern']
SHOW CONTRIBUTORS
SHOW CREATE DATABASE db_name
SHOW CREATE EVENT event_name
SHOW CREATE FUNCTION funcname
SHOW CREATE PROCEDURE procname
SHOW CREATE TABLE tbl_name
SHOW CREATE VIEW view_name
SHOW DATABASES [LIKE 'pattern']
SHOW ENGINE engine_name {LOGS | STATUS | MUTEX}
SHOW [STORAGE] ENGINES
SHOW ERRORS [LIMIT [offset,] row_count]
SHOW [FULL] EVENTS
SHOW FUNCTION STATUS [LIKE 'pattern']
SHOW GRANTS FOR user
SHOW INDEX FROM tbl_name [FROM db_name]
SHOW INNODB STATUS
SHOW PROCEDURE STATUS [LIKE 'pattern']
SHOW PLUGINS
SHOW PRIVILEGES
SHOW [FULL] PROCESSLIST
SHOW SCHEDULER STATUS
SHOW [GLOBAL | SESSION] STATUS [LIKE 'pattern']
SHOW TABLE STATUS [FROM db_name] [LIKE 'pattern']
SHOW [OPEN] TABLES [FROM db_name] [LIKE 'pattern']
SHOW TRIGGERS
SHOW [GLOBAL | SESSION] VARIABLES [LIKE 'pattern']
SHOW WARNINGS [LIMIT [offset,] row_count]
```

The `SHOW` statement also has forms that provide information about replication master and slave servers and are described in [Section 13.6, “Replication Statements”](#):

```
SHOW BINARY LOGS
SHOW BINLOG EVENTS
SHOW MASTER STATUS
SHOW SLAVE HOSTS
SHOW SLAVE STATUS
```

If the syntax for a given `SHOW` statement includes a `LIKE 'pattern'` part, `'pattern'` is a string that can contain the SQL `'%'` and `'_'` wildcard characters. The pattern is useful for restricting statement

output to matching values.

Several `SHOW` statements also accept a `WHERE` clause that provides more flexibility in specifying which rows to display. See [Section 22.27, “Extensions to SHOW Statements”](#).

13.5.4.1. SHOW AUTHORS Syntax

```
SHOW AUTHORS
```

The `SHOW AUTHORS` statement displays information about the people who work on MySQL. For each author, it displays `Name`, `Location`, and `Comment` values.

This statement was added in MySQL 5.1.3.

13.5.4.2. SHOW CHARACTER SET Syntax

```
SHOW CHARACTER SET [LIKE 'pattern']
```

The `SHOW CHARACTER SET` statement shows all available character sets. It takes an optional `LIKE` clause that indicates which character set names to match. For example:

```
mysql> SHOW CHARACTER SET LIKE 'latin%';
```

Charset	Description	Default collation	Maxlen
latin1	cp1252 West European	latin1_swedish_ci	1
latin2	ISO 8859-2 Central European	latin2_general_ci	1
latin5	ISO 8859-9 Turkish	latin5_turkish_ci	1
latin7	ISO 8859-13 Baltic	latin7_general_ci	1

The `Maxlen` column shows the maximum number of bytes required to store one character.

13.5.4.3. SHOW COLLATION Syntax

```
SHOW COLLATION [LIKE 'pattern']
```

The output from `SHOW COLLATION` includes all available character sets. It takes an optional `LIKE` clause whose `pattern` indicates which collation names to match. For example:

```
mysql> SHOW COLLATION LIKE 'latin1%';
```

Collation	Charset	Id	Default	Compiled	Sortlen
latin1_german1_ci	latin1	5			0
latin1_swedish_ci	latin1	8	Yes	Yes	0
latin1_danish_ci	latin1	15			0
latin1_german2_ci	latin1	31		Yes	2
latin1_bin	latin1	47		Yes	0
latin1_general_ci	latin1	48			0
latin1_general_cs	latin1	49			0
latin1_spanish_ci	latin1	94			0

The `Default` column indicates whether a collation is the default for its character set. `Compiled` indicates whether the character set is compiled into the server. `Sortlen` is related to the amount of memory required to sort strings expressed in the character set.

13.5.4.4. SHOW COLUMNS Syntax

```
SHOW [FULL] COLUMNS FROM tbl_name [FROM db_name] [LIKE 'pattern']
```

`SHOW COLUMNS` displays information about the columns in a given table. It also works for views.

The `FULL` keyword causes the output to include the privileges you have as well as any per-column comments for each column.

You can use `db_name.tbl_name` as an alternative to the `tbl_name FROM db_name` syntax. In other words, these two statements are equivalent:

```
mysql> SHOW COLUMNS FROM mytable FROM mydb;
mysql> SHOW COLUMNS FROM mydb.mytable;
```

`SHOW FIELDS` is a synonym for `SHOW COLUMNS`. You can also list a table's columns with the `mysqlshow db_name tbl_name` command.

The `DESCRIBE` statement provides information similar to `SHOW COLUMNS`. See [Section 13.3.1, “DESCRIBE Syntax”](#).

13.5.4.5. SHOW CONTRIBUTORS Syntax

```
SHOW CONTRIBUTORS
```

The `SHOW CONTRIBUTORS` statement displays information about the people who contribute to MySQL source or to causes that MySQL AB supports. For each contributor, it displays `Name`, `Location`, and `Comment` values.

This statement was added in MySQL 5.1.12.

13.5.4.6. SHOW CREATE DATABASE Syntax

```
SHOW CREATE {DATABASE | SCHEMA} db_name
```

Shows the `CREATE DATABASE` statement that creates the given database. `SHOW CREATE SCHEMA` is a synonym for `SHOW CREATE DATABASE`.

```
mysql> SHOW CREATE DATABASE test\G
***** 1. row *****
      Database: test
Create Database: CREATE DATABASE `test`
                  /*!40100 DEFAULT CHARACTER SET latin1 */

mysql> SHOW CREATE SCHEMA test\G
***** 1. row *****
      Database: test
Create Database: CREATE DATABASE `test`
                  /*!40100 DEFAULT CHARACTER SET latin1 */
```

`SHOW CREATE DATABASE` quotes table and column names according to the value of the `SQL_QUOTE_SHOW_CREATE` option. See [Section 13.5.3, “SET Syntax”](#).

13.5.4.7. SHOW CREATE EVENT

```
SHOW CREATE EVENT event_name
```

This statement displays the `CREATE TABLE` statement needed to re-create a given event. For example (using the same event `e_daily` defined and then altered in [Section 13.5.4.15, “SHOW EVENTS”](#)):

```
mysql> SHOW CREATE EVENT test.e_daily\G
***** 1. row *****
      Event: e_daily
```

```

Create Event: CREATE EVENT e_daily
              ON SCHEDULE EVERY 1 DAY
              STARTS CURRENT_TIMESTAMP + INTERVAL 6 HOUR
              ENABLE
              COMMENT 'Saves total number of sessions and
                      clears the table once per day.'
              DO
                BEGIN
                  INSERT INTO site_activity.totals (when, total)
                    SELECT CURRENT_TIMESTAMP, COUNT(*)
                      FROM site_activity.sessions;
                  DELETE FROM site_activity.sessions;
                END

```

Note that the output reflects the current status of the event ([ENABLE](#)) rather than the status with which it was created.

This statement was implemented in MySQL 5.1.6.

13.5.4.8. SHOW CREATE PROCEDURE and SHOW CREATE FUNCTION Syntax

```
SHOW CREATE {PROCEDURE | FUNCTION} sp_name
```

This statement is a MySQL extension. Similar to [SHOW CREATE TABLE](#), it returns the exact string that can be used to re-create the named routine.

```

mysql> SHOW CREATE FUNCTION test.hello\G
***** 1. row *****
      Function: hello
      sql_mode:
Create Function: CREATE FUNCTION `test`.`hello`(s CHAR(20)) »
                  RETURNS CHAR(50)
                  RETURN CONCAT('Hello, ',s, '!')

```

13.5.4.9. SHOW CREATE TABLE Syntax

```
SHOW CREATE TABLE tbl_name
```

Shows the [CREATE TABLE](#) statement that creates the given table. This statement also works with views.

```

mysql> SHOW CREATE TABLE t\G
***** 1. row *****
      Table: t
Create Table: CREATE TABLE t (
  id INT(11) default NULL auto_increment,
  s char(60) default NULL,
  PRIMARY KEY (id)
) ENGINE=MyISAM

```

[SHOW CREATE TABLE](#) quotes table and column names according to the value of the [SQL_QUOTE_SHOW_CREATE](#) option. See [Section 13.5.3, “SET Syntax”](#).

13.5.4.10. SHOW CREATE VIEW Syntax

```
SHOW CREATE VIEW view_name
```

This statement shows a [CREATE VIEW](#) statement that creates the given view.

```
mysql> SHOW CREATE VIEW v;
```

```
+-----+-----+
| View | Create View |
+-----+-----+
| v    | CREATE VIEW `test`.`v` AS select 1 AS `a`,2 AS `b` |
+-----+-----+
```

Use of `SHOW CREATE VIEW` requires the `SHOW VIEW` privilege and the `SELECT` privilege for the view in question.

You can also obtain information about view objects from `INFORMATION_SCHEMA`, which contains a `VIEWS` table. See [Section 22.15, “The INFORMATION_SCHEMA VIEWS Table”](#).

13.5.4.11. SHOW DATABASES Syntax

```
SHOW {DATABASES | SCHEMAS} [LIKE 'pattern']
```

`SHOW DATABASES` lists the databases on the MySQL server host. `SHOW SCHEMAS` is a synonym for `SHOW DATABASES`.

You see only those databases for which you have some kind of privilege, unless you have the global `SHOW DATABASES` privilege. You can also get this list using the `mysqlshow` command.

If the server was started with the `--skip-show-database` option, you cannot use this statement at all unless you have the `SHOW DATABASES` privilege.

`SHOW SCHEMAS` can also be used.

13.5.4.12. SHOW ENGINE Syntax

```
SHOW ENGINE engine_name {LOGS | STATUS | MUTEX}
```

`SHOW ENGINE` displays log or status information about a storage engine. The following statements currently are supported:

```
SHOW ENGINE INNODB STATUS
SHOW ENGINE INNODB MUTEX
```

Older (and now deprecated) synonyms for these statements are `SHOW INNODB STATUS` and `SHOW MUTEX STATUS`.

`SHOW ENGINE INNODB STATUS` displays extensive information about the state of the `InnoDB` storage engine.

The `InnoDB` Monitors provide additional information about `InnoDB` processing. See [Section 14.5.11.1, “SHOW ENGINE INNODB STATUS and the InnoDB Monitors”](#).

`SHOW ENGINE INNODB MUTEX` displays `InnoDB` mutex statistics. The output fields are:

- `Type`

Always `InnoDB`.

- `Name`

The mutex name and the source file where it is implemented. Example:
`&pool->mutex:mem0pool.c`

The mutex name indicates its purpose. For example, the `log_sys` mutex is used by the `InnoDB`

logging subsystem and indicates how intensive logging activity is. The `buf_pool` mutex protects the `InnoDB` buffer pool.

- `Status`

The mutex status. The fields contains several values:

- `count` indicates how many times the mutex was requested.
- `spin_waits` indicates how many times the spinlock had to run.
- `spin_rounds` indicates the number of spinlock rounds. (`spin_rounds` divided by `spin_waits` provides the average round count.)
- `os_waits` indicates the number of operating system waits. This occurs when the spinlock did not work (the mutex was not locked during the spinlock and it was necessary to yield to the operating system and wait).
- `os_yields` indicates the number of times a the thread trying to lock a mutex gave up its timeslice and yielded to the operating system (on the presumption that allowing other threads to run will free the mutex so that it can be locked).
- `os_wait_times` indicates the amount of time (in ms) spent in operating system waits, if the `timed_mutexes` system variable is 1 (`ON`). If `timed_mutexes` is 0 (`OFF`), timing is disabled, so `os_wait_times` is 0. `timed_mutexes` is off by default.

Information from this statement can be used to diagnose system problems. For example, large values of `spin_waits` and `spin_rounds` may indicate scalability problems.

In MySQL 5.0, `SHOW ENGINE INNODB MUTEX` is invoked as `SHOW MUTEX STATUS`. The latter statement displays similar information but in a somewhat different output format.

13.5.4.13. SHOW ENGINES Syntax

```
SHOW [STORAGE] ENGINES
```

`SHOW ENGINES` displays status information about the server's storage engines. This is particularly useful for checking whether a storage engine is supported, or to see what the default engine is. `SHOW TABLE TYPES` is a deprecated synonym.

```
mysql> SHOW ENGINES\G
***** 1. row *****
  Engine: MEMORY
  Support: YES
  Comment: Hash based, stored in memory, useful for temporary tables
  Transactions: NO
    XA: NO
  Savepoints: NO
***** 2. row *****
  Engine: MyISAM
  Support: DEFAULT
  Comment: Default engine as of MySQL 3.23 with great performance
  Transactions: NO
    XA: NO
  Savepoints: NO
***** 3. row *****
  Engine: InnoDB
  Support: YES
  Comment: Supports transactions, row-level locking, and foreign keys
  Transactions: YES
    XA: YES
  Savepoints: YES
***** 4. row *****
  Engine: EXAMPLE
```

```

Support: YES
Comment: Example storage engine
Transactions: NO
  XA: NO
  Savepoints: NO
***** 5. row *****
  Engine: ARCHIVE
  Support: YES
  Comment: Archive storage engine
Transactions: NO
  XA: NO
  Savepoints: NO
***** 6. row *****
  Engine: CSV
  Support: YES
  Comment: CSV storage engine
Transactions: NO
  XA: NO
  Savepoints: NO
***** 7. row *****
  Engine: BLACKHOLE
  Support: YES
  Comment: /dev/null storage engine (anything you write »
to it disappears)
Transactions: NO
  XA: NO
  Savepoints: NO
***** 8. row *****
  Engine: FEDERATED
  Support: YES
  Comment: Federated MySQL storage engine
Transactions: NO
  XA: NO
  Savepoints: NO
***** 9. row *****
  Engine: MRG_MYISAM
  Support: YES
  Comment: Collection of identical MyISAM tables
Transactions: NO
  XA: NO
  Savepoints: NO

```

The output from `SHOW ENGINES` may vary according to the MySQL version used and other factors. The values shown in the `Support` column indicate the server's level of support for different features, as shown here:

Value	Meaning
YES	The feature is supported and is active.
NO	The feature is not supported.
DISABLED	The feature is supported but has been disabled.

A value of `NO` means that the server was compiled without support for the feature, so it cannot be activated at runtime.

A value of `DISABLED` occurs either because the server was started with an option that disables the feature, or because not all options required to enable it were given. In the latter case, the error log file should contain a reason indicating why the option is disabled. See [Section 5.12.2, “The Error Log”](#).

You might also see `DISABLED` for a storage engine if the server was compiled to support it, but was started with a `--skip-engine` option. For example, `--skip-innodb` disables the `InnoDB` engine. For the `NDB Cluster` storage engine, `DISABLED` means the server was compiled with support for MySQL Cluster, but was not started with the `--ndb-cluster` option.

All MySQL servers support `MyISAM` tables, because `MyISAM` is the default storage engine.

The `Transactions`, `XA`, and `Savepoints` columns were added in MySQL 5.1.2. They indicate whether the storage engine supports transactions, XA transactions, and savepoints, respectively.

13.5.4.14. SHOW ERRORS Syntax

```
SHOW ERRORS [LIMIT [offset,] row_count]
SHOW COUNT(*) ERRORS
```

This statement is similar to [SHOW WARNINGS](#), except that instead of displaying errors, warnings, and notes, it displays only errors.

The [LIMIT](#) clause has the same syntax as for the [SELECT](#) statement. See [Section 13.2.7, “SELECT Syntax”](#).

The [SHOW COUNT\(*\) ERRORS](#) statement displays the number of errors. You can also retrieve this number from the `error_count` variable:

```
SHOW COUNT(*) ERRORS;
SELECT @@error_count;
```

For more information, see [Section 13.5.4.30, “SHOW WARNINGS Syntax”](#).

13.5.4.15. SHOW EVENTS

```
SHOW EVENTS [FROM schema_name] [LIKE pattern]
```

In its simplest form, [SHOW EVENTS](#) lists all of the events in the current schema:

```
mysql> SELECT CURRENT_USER(), SCHEMA();
+-----+-----+
| CURRENT_USER() | SCHEMA() |
+-----+-----+
| jon@ghidora   | myschema |
+-----+-----+
1 row in set (0.00 sec)

mysql> SHOW EVENTS\G
***** 1. row *****
      Db: myschema
      Name: e_daily
      Definer: jon@ghidora
      Type: RECURRING
      Execute at: NULL
      Interval value: 10
      Interval field: INTERVAL_SECOND
      Starts: 2006-02-09 10:41:23
      Ends: 0000-00-00 00:00:00
      Status: ENABLED
1 row in set (0.01 sec)
```

The columns in the output of [SHOW EVENTS](#) — which are similar to, but not identical to the columns in the [INFORMATION_SCHEMA.EVENTS](#) table — are shown here:

- **Db:** The schema (database) on which the event is defined.
- **Name:** The name of the event.
- **Definer:** The user account (`username@hostname`) which created the event.
- **Type:** One of the two values [ONE TIME](#) (transient) or [RECURRING](#).
- **Execute At:** The date and time when a transient event is set to execute. Shown as a [DATETIME](#) value.

For a recurring event, the value of this column is always [NULL](#).

- **Interval Value:** For a recurring event, the number of intervals to wait between event executions.

For a transient event, the value of this column is always `NULL`.

- **Interval Field:** The time units used for the interval which a recurring event waits before repeating.

For a transient event, the value of this column is always `NULL`.

- **Starts:** The start date and time for a recurring event. This is displayed as a `DATETIME` value, and is empty if no start date and time are defined for the event. (Prior to MySQL 5.1.8, it defaulted to `'0000-00-00 00:00:00'` in such cases.)

For a transient event, the value of this column is always `NULL`.

- **Ends:** The end date and time for a recurring event. This is displayed as a `DATETIME` value, and defaults to `'0000-00-00 00:00:00'` if no end date and time is defined for the event.

For a transient event, the value of this column is always `NULL`.

- **Status:** The event status. One of `ENABLED` or `DISABLED`.

Note that the action statement is not shown in the output of `SHOW EVENTS`.

Note: The values displayed for `Starts` and `Ends` (other than `'0000-00-00 00:00:00'`) are currently shown using Universal Time. However, *the use of Universal Time in this context is expected to change, so you should not rely upon it in your applications* ([Bug#16420](http://bugs.mysql.com/16420) [<http://bugs.mysql.com/16420>]). See also [Section 22.20](#), “The `INFORMATION_SCHEMA EVENTS` Table”.

To see events for a different schema, you can use the `FROM` clause. For example, if the `test` schema had been selected in the preceding example, you could view events defined on `myschema` using the following statement:

```
SHOW EVENTS FROM myschema;
```

You can filter the list returned by this statement on the event name using `LIKE` plus a pattern.

This statement was added in MySQL 5.1.6.

See also [Section 22.20](#), “The `INFORMATION_SCHEMA EVENTS` Table”.

Note: In MySQL 5.1.11 and earlier, `SHOW EVENTS` displayed only those events for which the current user was the definer, and the `SHOW FULL EVENTS` statement was used for viewing events defined by all users on a given schema. `SHOW FULL EVENTS` was removed in MySQL 5.1.12.

13.5.4.16. SHOW GRANTS Syntax

```
SHOW GRANTS FOR user
```

This statement lists the `GRANT` statement or statements that must be issued to duplicate the privileges that are granted to a MySQL user account. The account is named using the same format as for the `GRANT` statement; for example, `'jeffrey'@'localhost'`. The user and host parts of the account name correspond to the `User` and `Host` column values of the `user` table row for the account.

```
mysql> SHOW GRANTS FOR 'root'@'localhost';
+-----+
```

```
| Grants for root@localhost |
+-----+
| GRANT ALL PRIVILEGES ON *.* TO 'root'@'localhost' WITH GRANT OPTION |
+-----+
```

To list the privileges granted to the account that you are using to connect to the server, you can use any of the following statements:

```
SHOW GRANTS;
SHOW GRANTS FOR CURRENT_USER;
SHOW GRANTS FOR CURRENT_USER();
```

As of MySQL 5.1.12, if `SHOW GRANTS FOR CURRENT_USER` (or any of the equivalent syntaxes) is used in `DEFINER` context, such as within a stored procedure that is defined with `SQL SECURITY DEFINER`, the grants displayed are those of the definer and not the invoker.

`SHOW GRANTS` displays only the privileges granted explicitly to the named account. Other privileges might be available to the account, but they are not displayed. For example, if an anonymous account exists, the named account might be able to use its privileges, but `SHOW GRANTS` will not display them.

13.5.4.17. SHOW INDEX Syntax

```
SHOW INDEX FROM tbl_name [FROM db_name]
```

`SHOW INDEX` returns table index information. The format resembles that of the `SQLStatistics` call in ODBC.

`SHOW INDEX` returns the following fields:

- `Table`
The name of the table.
- `Non_unique`
0 if the index cannot contain duplicates, 1 if it can.
- `Key_name`
The name of the index.
- `Seq_in_index`
The column sequence number in the index, starting with 1.
- `Column_name`
The column name.
- `Collation`
How the column is sorted in the index. In MySQL, this can have values 'A' (Ascending) or `NULL` (Not sorted).
- `Cardinality`
An estimate of the number of unique values in the index. This is updated by running `ANALYZE TABLE` or `myisamchk -a`. `Cardinality` is counted based on statistics stored as integers, so the value is not necessarily exact even for small tables. The higher the cardinality, the greater the chance

that MySQL uses the index when doing joins.

- `Sub_part`

The number of indexed characters if the column is only partly indexed, `NULL` if the entire column is indexed.

- `Packed`

Indicates how the key is packed. `NULL` if it is not.

- `Null`

Contains `YES` if the column may contain `NULL`. If not, the column contains `NO`.

- `Index_type`

The index method used (`BTREE`, `FULLTEXT`, `HASH`, `RTREE`).

- `Comment`

Various remarks.

You can use `db_name.tbl_name` as an alternative to the `tbl_name FROM db_name` syntax. These two statements are equivalent:

```
SHOW INDEX FROM mytable FROM mydb;  
SHOW INDEX FROM mydb.mytable;
```

`SHOW KEYS` is a synonym for `SHOW INDEX`. You can also list a table's indexes with the `mysqlshow -k db_name tbl_name` command.

13.5.4.18. SHOW INNODB STATUS Syntax

```
SHOW INNODB STATUS
```

In MySQL 5.1, this is a deprecated synonym for `SHOW ENGINE INNODB STATUS`. See [Section 13.5.4.12, “SHOW ENGINE Syntax”](#).

13.5.4.19. SHOW OPEN TABLES Syntax

```
SHOW OPEN TABLES [FROM db_name] [LIKE 'pattern']
```

`SHOW OPEN TABLES` lists the non-`TEMPORARY` tables that are currently open in the table cache. See [Section 7.4.8, “How MySQL Opens and Closes Tables”](#).

`SHOW OPEN TABLES` returns the following fields:

- `Database`

The database containing the table.

- `Table`

The table name.

- `In_use`

The number of times the table currently is in use by queries. If the count is zero, the table is open, but not currently being used.

- `Name_locked`

Whether the table name is locked. Name locking is used for operations such as dropping or renaming tables.

13.5.4.20. SHOW PLUGINS Syntax

```
SHOW PLUGINS
```

`SHOW PLUGINS` displays information about known plugins.

```
mysql> SHOW PLUGINS;
+-----+-----+-----+-----+
| Name          | Status | Type          | Library |
+-----+-----+-----+-----+
| MEMORY        | ACTIVE | STORAGE ENGINE | NULL    |
| MyISAM        | ACTIVE | STORAGE ENGINE | NULL    |
| InnoDB        | ACTIVE | STORAGE ENGINE | NULL    |
| ARCHIVE       | ACTIVE | STORAGE ENGINE | NULL    |
| CSV           | ACTIVE | STORAGE ENGINE | NULL    |
| BLACKHOLE     | ACTIVE | STORAGE ENGINE | NULL    |
| FEDERATED     | ACTIVE | STORAGE ENGINE | NULL    |
| MRG_MYISAM    | ACTIVE | STORAGE ENGINE | NULL    |
+-----+-----+-----+-----+
```

`SHOW PLUGIN` was added in MySQL 5.1.5 and renamed to `SHOW PLUGINS` in 5.1.9. (As of 5.1.9, `SHOW PLUGIN` is deprecated and generates a warning.)

13.5.4.21. SHOW PRIVILEGES Syntax

```
SHOW PRIVILEGES
```

`SHOW PRIVILEGES` shows the list of system privileges that the MySQL server supports. The exact list of privileges depends on the version of your server.

```
mysql> SHOW PRIVILEGES\G
***** 1. row *****
Privilege: Alter
Context: Tables
Comment: To alter the table
***** 2. row *****
Privilege: Alter routine
Context: Functions,Procedures
Comment: To alter or drop stored functions/procedures
***** 3. row *****
Privilege: Create
Context: Databases,Tables,Indexes
Comment: To create new databases and tables
***** 4. row *****
Privilege: Create routine
Context: Functions,Procedures
Comment: To use CREATE FUNCTION/PROCEDURE
***** 5. row *****
Privilege: Create temporary tables
Context: Databases
Comment: To use CREATE TEMPORARY TABLE
...
```

13.5.4.22. SHOW PROCEDURE STATUS and SHOW FUNCTION STATUS

Syntax

```
SHOW {PROCEDURE | FUNCTION} STATUS [LIKE 'pattern']
```

This statement is a MySQL extension. It returns characteristics of routines, such as the database, name, type, creator, and creation and modification dates. If no pattern is specified, the information for all stored procedures or all stored functions is listed, depending on which statement you use.

```
mysql> SHOW FUNCTION STATUS LIKE 'hello'\G
***** 1. row *****
      Db: test
      Name: hello
      Type: FUNCTION
      Definer: testuser@localhost
      Modified: 2004-08-03 15:29:37
      Created: 2004-08-03 15:29:37
      Security_type: DEFINER
      Comment:
```

You can also get information about stored routines from the `ROUTINES` table in `INFORMATION_SCHEMA`. See [Section 22.14, “The INFORMATION_SCHEMA ROUTINES Table”](#).

13.5.4.23. SHOW PROCESSLIST Syntax

```
SHOW [FULL] PROCESSLIST
```

`SHOW PROCESSLIST` shows you which threads are running. You can also get this information using the `mysqladmin processlist` command. If you have the `PROCESS` privilege, you can see all threads. Otherwise, you can see only your own threads (that is, threads associated with the MySQL account that you are using). See [Section 13.5.5.3, “KILL Syntax”](#). If you do not use the `FULL` keyword, only the first 100 characters of each statement are shown in the `Info` field.

This statement is very useful if you get the “too many connections” error message and want to find out what is going on. MySQL reserves one extra connection to be used by accounts that have the `SUPER` privilege, to ensure that administrators should always be able to connect and check the system (assuming that you are not giving this privilege to all your users).

The output of `SHOW PROCESSLIST` may look like this:

```
mysql> SHOW FULL PROCESSLIST\G
***** 1. row *****
Id: 1
User: system user
Host:
db: NULL
Command: Connect
Time: 1030455
State: Waiting for master to send event
Info: NULL
***** 2. row *****
Id: 2
User: system user
Host:
db: NULL
Command: Connect
Time: 1004
State: Has read all relay log; waiting for the slave »
      I/O thread to update it
Info: NULL
***** 3. row *****
Id: 3112
User: replikator
Host: artemis:2204
db: NULL
Command: Binlog Dump
Time: 2144
State: Has sent all binlog to slave; waiting for binlog to be updated
```

```

Info: NULL
***** 4. row *****
Id: 3113
User: replikator
Host: iconnect2:45781
db: NULL
Command: Binlog Dump
Time: 2086
State: Has sent all binlog to slave; waiting for binlog to be updated
Info: NULL
***** 5. row *****
Id: 3123
User: stefan
Host: localhost
db: apollon
Command: Query
Time: 0
State: NULL
Info: SHOW FULL PROCESSLIST
5 rows in set (0.00 sec)

```

The columns have the following meaning:

- **Id**

The connection identifier.

- **User**

The MySQL user who issued the statement. If this is `system user`, it refers to a non-client thread spawned by the server to handle tasks internally. This could be the I/O or SQL thread used on replication slaves or a delayed-row handler. `event_scheduler` refers to the thread that monitors scheduled events. For `system user` or `event_scheduler`, there is no host specified in the `Host` column.

- **Host**

The hostname of the client issuing the statement (except for `system user` where there is no host). `SHOW PROCESSLIST` reports the hostname for TCP/IP connections in `host_name:client_port` format to make it easier to determine which client is doing what.

- **db**

The default database, if one is selected, otherwise `NULL`.

- **Command**

The value of that column corresponds to the `COM_xxx` commands of the client/server protocol. See [Section 5.2.5, “Status Variables”](#)

The `Command` value may be one of the following: `Binlog Dump`, `Change user`, `Close stmt`, `Connect`, `Connect Out`, `Create DB`, `Daemon`, `Debug`, `Delayed insert`, `Drop DB`, `Error`, `Execute`, `Fetch`, `Field List`, `Init DB`, `Kill`, `Long Data`, `Ping`, `Prepare`, `Processlist`, `Query`, `Quit`, `Refresh`, `Register Slave`, `Reset stmt`, `Set option`, `Shutdown`, `Sleep`, `Statistics`, `Table Dump`, `Time`

- **Time**

The time in seconds between the start of the statement or command and now.

- **State**

An action, event, or state, which can be one of the following: `After create`, `Analyzing`,

Changing master, Checking master version, Checking table, Connecting to master, Copying to group table, Copying to tmp table, Creating delayed handler, Creating index, Creating sort index, Creating table from master dump, Creating tmp table, Execution of `init_command`, FULLTEXT initialization, Finished reading one binlog; switching to next binlog, Flushing tables, Killed, Killing slave, Locked, Making temp file, Opening master dump table, Opening table, Opening tables, Processing request, Purging old relay logs, Queueing master event to the relay log, Reading event from the relay log, Reading from net, Reading master dump table data, Rebuilding the index on master dump table, Reconnecting after a failed binlog dump request, Reconnecting after a failed master event read, Registering slave on master, Removing duplicates, Reopen tables, Repair by sorting, Repair done, Repair with keycache, Requesting binlog dump, Rolling back, Saving state, Searching rows for update, Sending binlog event to slave, Sending data, Sorting for group, Sorting for order, Sorting index, Sorting result, System lock, Table lock, Thread initialized, Updating, User lock, Waiting for INSERT, Waiting for master to send event, Waiting for master update, Waiting for slave mutex on exit, Waiting for table, Waiting for tables, Waiting for the next event in relay log, Waiting on cond, Waiting to finalize termination, Waiting to reconnect after a failed binlog dump request, Waiting to reconnect after a failed master event read, Writing to net, allocating local table, cleaning up, closing tables, converting HEAP to MyISAM, copy to tmp table, creating table, deleting from main table, deleting from reference tables, `discard_or_import_tablespace`, end, freeing items, got handler lock, got old table, info, init, insert, logging slow query, login, preparing, purging old relay logs, query end, removing tmp table, rename, rename result table, reschedule, setup, starting slave, statistics, storing row into queue, unauthenticated user, update, updating, updating main table, updating reference tables, upgrading lock, waiting for `delay_list`, waiting for handler insert, waiting for handler lock, waiting for handler open, Waiting for event from `ndbcluster`

The most common `State` values are described in the rest of this section. Most of the other `State` values are useful only for finding bugs in the server. See also [Section 6.4, “Replication Implementation Details”](#), for additional information about process states for replication servers.

For the `SHOW PROCESSLIST` statement, the value of `State` is `NULL`.

- `Info`

The statement that the thread is executing, or `NULL` if it is not executing any statement.

Some `State` values commonly seen in the output from `SHOW PROCESSLIST`:

- `Checking table`

The thread is performing a table check operation.

- `Closing tables`

Means that the thread is flushing the changed table data to disk and closing the used tables. This should be a fast operation. If not, you should verify that you do not have a full disk and that the disk is not in very heavy use.

- `Connect Out`

A replication slave is connecting to its master.

- `Copying to group table`

If a statement has different `ORDER BY` and `GROUP BY` criteria, the rows are sorted by group and copied to a temporary table.

- `Copying to tmp table`

The server is copying to a temporary table in memory.

- `Copying to tmp table on disk`

The server is copying to a temporary table on disk. The temporary result set was larger than `tmp_table_size` and the thread is changing the temporary table from in-memory to disk-based format to save memory.

- `Creating tmp table`

The thread is creating a temporary table to hold a part of the result for the query.

- `deleting from main table`

The server is executing the first part of a multiple-table delete. It is deleting only from the first table, and saving fields and offsets to be used for deleting from the other (reference) tables.

- `deleting from reference tables`

The server is executing the second part of a multiple-table delete and deleting the matched rows from the other tables.

- `Flushing tables`

The thread is executing `FLUSH TABLES` and is waiting for all threads to close their tables.

- `FULLTEXT initialization`

The server is preparing to perform a natural-language full-text search.

- `Killed`

Someone has sent a `KILL` statement to the thread and it should abort next time it checks the kill flag. The flag is checked in each major loop in MySQL, but in some cases it might still take a short time for the thread to die. If the thread is locked by some other thread, the kill takes effect as soon as the other thread releases its lock.

- `Locked`

The query is locked by another query.

- `Sending data`

The thread is processing rows for a `SELECT` statement and also is sending data to the client.

- `Sorting for group`

The thread is doing a sort to satisfy a `GROUP BY`.

- `Sorting for order`

The thread is doing a sort to satisfy a `ORDER BY`.

- `Opening tables`

The thread is trying to open a table. This should be a very fast procedure, unless something prevents opening. For example, an `ALTER TABLE` or a `LOCK TABLE` statement can prevent opening a table until the statement is finished.

- `Reading from net`

The server is reading a packet from the network.

- `Removing duplicates`

The query was using `SELECT DISTINCT` in such a way that MySQL could not optimize away the distinct operation at an early stage. Because of this, MySQL requires an extra stage to remove all duplicated rows before sending the result to the client.

- `Reopen table`

The thread got a lock for the table, but noticed after getting the lock that the underlying table structure changed. It has freed the lock, closed the table, and is trying to reopen it.

- `Repair by sorting`

The repair code is using a sort to create indexes.

- `Repair with keycache`

The repair code is using creating keys one by one through the key cache. This is much slower than `Repair by sorting`.

- `Searching rows for update`

The thread is doing a first phase to find all matching rows before updating them. This has to be done if the `UPDATE` is changing the index that is used to find the involved rows.

- `Sleeping`

The thread is waiting for the client to send a new statement to it.

- `statistics`

The server is calculating statistics to develop a query execution plan.

- `System lock`

The thread is waiting to get an external system lock for the table. If you are not using multiple `mysqld` servers that are accessing the same tables, you can disable system locks with the `-skip-external-locking` option.

- `unauthenticated user`

The state of a thread that has become associated with a client connection but for which authentication of the client user has not yet been done.

- `Upgrading lock`

The `INSERT DELAYED` handler is trying to get a lock for the table to insert rows.

- `Updating`
The thread is searching for rows to update and is updating them.
- `updating main table`
The server is executing the first part of a multiple-table update. It is updating only the first table, and saving fields and offsets to be used for updating the other (reference) tables.
- `updating reference tables`
The server is executing the second part of a multiple-table update and updating the matched rows from the other tables.
- `User Lock`
The thread is waiting on a `GET_LOCK()`.
- `Waiting for event from ndbcluster`
The server is acting as an SQL node in a MySQL Cluster, and is connected to a cluster management node.
- `Waiting for tables`
The thread got a notification that the underlying structure for a table has changed and it needs to reopen the table to get the new structure. However, to reopen the table, it must wait until all other threads have closed the table in question.

This notification takes place if another thread has used `FLUSH TABLES` or one of the following statements on the table in question: `FLUSH TABLES tbl_name`, `ALTER TABLE`, `RENAME TABLE`, `REPAIR TABLE`, `ANALYZE TABLE`, or `OPTIMIZE TABLE`.
- `waiting for handler insert`
The `INSERT DELAYED` handler has processed all pending inserts and is waiting for new ones.
- `Writing to net`
The server is writing a packet to the network.

Most states correspond to very quick operations. If a thread stays in any of these states for many seconds, there might be a problem that needs to be investigated.

13.5.4.24. `SHOW SCHEDULER STATUS` Syntax

```
SHOW SCHEDULER STATUS
```

This statement provides debugging information regarding the Event Scheduler's state. It is supported only in `-debug` builds of MySQL 5.1.11, and was removed in 5.1.12 and subsequent releases.

Sample output is shown here:

Name	Value
<code>scheduler state</code>	<code>INITIALIZED</code>
<code>thread_id</code>	<code>NULL</code>
<code>scheduler last locked at</code>	<code>init_scheduler::313</code>
<code>scheduler last unlocked at</code>	<code>init_scheduler::318</code>

scheduler waiting on condition	0	
scheduler workers count	0	
scheduler executed events	0	
scheduler data locked	0	
queue element count	1	
queue data locked	0	
queue data attempting lock	0	
queue last locked at		create_event::218
queue last unlocked at		create_event::222
queue last attempted lock at		::0
queue waiting on condition	0	
next activation at		0-00-00 00:00:00

In MySQL 5.1.12 and later, this information can be obtained using `mysqladmin debug`. (See [Section 8.8, “mysqladmin — Client for Administering a MySQL Server”](#).) For more information about obtaining Event Scheduler status information, see [Section 20.4, “Event Scheduler Status”](#).

13.5.4.25. SHOW STATUS Syntax

```
SHOW [GLOBAL | SESSION] STATUS [LIKE 'pattern']
```

`SHOW STATUS` provides server status information. This information also can be obtained using the `mysqladmin extended-status` command.

Partial output is shown here. The list of names and values may be different for your server. The meaning of each variable is given in [Section 5.2.5, “Status Variables”](#).

```
mysql> SHOW STATUS;
```

Variable_name	Value
Aborted_clients	0
Aborted_connects	0
Bytes_received	155372598
Bytes_sent	1176560426
Connections	30023
Created_tmp_disk_tables	0
Created_tmp_tables	8340
Created_tmp_files	60
..	
Open_tables	1
Open_files	2
Open_streams	0
Opened_tables	44600
Questions	2026873
..	
Table_locks_immediate	1920382
Table_locks_waited	0
Threads_cached	0
Threads_created	30022
Threads_connected	1
Threads_running	1
Uptime	80380

With a `LIKE` clause, the statement displays only rows for those variables with names that match the pattern:

```
mysql> SHOW STATUS LIKE 'Key%';
```

Variable_name	Value
Key_blocks_used	14955
Key_read_requests	96854827
Key_reads	162040
Key_write_requests	7589728
Key_writes	3813196

With the `GLOBAL` modifier, `SHOW STATUS` displays the status values for all connections to MySQL. With `SESSION`, it displays the status values for the current connection. If no modifier is present, the default is `SESSION`. `LOCAL` is a synonym for `SESSION`.

Some status variables have only a global value. For these, you get the same value for both `GLOBAL` and `SESSION`.

13.5.4.26. `SHOW TABLE STATUS` Syntax

```
SHOW TABLE STATUS [FROM db_name] [LIKE 'pattern']
```

`SHOW TABLE STATUS` works like `SHOW TABLE`, but provides a lot of information about each table. You can also get this list using the `mysqlshow --status db_name` command.

This statement also displays information about views.

`SHOW TABLE STATUS` returns the following fields:

- `Name`
The name of the table.
- `Engine`
The storage engine for the table. See [Chapter 14, Storage Engines and Table Types](#).
- `Version`
The version number of the table's `.frm` file.
- `Row_format`
The row storage format (`Fixed`, `Dynamic`, `Compressed`, `Redundant`, `Compact`). The format of InnoDB tables is reported as `Redundant` or `Compact`.
- `Rows`
The number of rows. Some storage engines, such as `MyISAM`, store the exact count. For other storage engines, such as `InnoDB`, this value is an approximation, and may vary from the actual value by as much as 40 to 50%. In such cases, use `SELECT COUNT(*)` to obtain an accurate count.
The `Rows` value is `NULL` for tables in the `INFORMATION_SCHEMA` database.
- `Avg_row_length`
The average row length.
- `Data_length`
The length of the data file.
- `Max_data_length`
The maximum length of the data file. This is the total number of bytes of data that can be stored in the table, given the data pointer size used.
- `Index_length`

The length of the index file.

- `Data_free`

The number of allocated but unused bytes.

- `Auto_increment`

The next `AUTO_INCREMENT` value.

- `Create_time`

When the table was created.

- `Update_time`

When the data file was last updated. For some storage engines, this value is `NULL`. For example, `InnoDB` stores multiple tables in its tablespace and the data file timestamp does not apply.

- `Check_time`

When the table was last checked. Not all storage engines update this time, in which case the value is always `NULL`.

- `Collation`

The table's character set and collation.

- `Checksum`

The live checksum value (if any).

- `Create_options`

Extra options used with `CREATE TABLE`.

- `Comment`

The comment used when creating the table (or information as to why MySQL could not access the table information).

In the table comment, `InnoDB` tables report the free space of the tablespace to which the table belongs. For a table located in the shared tablespace, this is the free space of the shared tablespace. If you are using multiple tablespaces and the table has its own tablespace, the free space is for only that table.

For `MEMORY` tables, the `Data_length`, `Max_data_length`, and `Index_length` values approximate the actual amount of allocated memory. The allocation algorithm reserves memory in large amounts to reduce the number of allocation operations.

For `NDB Cluster` tables, the output of this statement shows appropriate values for the `Avg_row_length` and `Data_length` columns, with the exception that `BLOB` columns are not taken into account. In addition, the number of replicas is shown in the `Comment` column (as `number_of_replicas`).

For views, all the fields displayed by `SHOW TABLE STATUS` are `NULL` except that `Name` indicates the view name and `Comment` says `view`.

13.5.4.27. SHOW TABLES Syntax

```
SHOW [FULL] TABLES [FROM db_name] [LIKE 'pattern']
```

`SHOW TABLES` lists the non-`TEMPORARY` tables in a given database. You can also get this list using the `mysqlshow db_name` command.

This statement also lists any views in the database. The `FULL` modifier is supported such that `SHOW FULL TABLES` displays a second output column. Values for the second column are `BASE TABLE` for a table and `VIEW` for a view.

Note: If you have no privileges for a table, the table does not show up in the output from `SHOW TABLES` or `mysqlshow db_name`.

13.5.4.28. SHOW TRIGGERS Syntax

```
SHOW TRIGGERS [FROM db_name] [LIKE expr]
```

`SHOW TRIGGERS` lists the triggers currently defined on the MySQL server. This statement requires the `SUPER` privilege.

For the trigger `ins_sum` as defined in [Section 19.3, “Using Triggers”](#), the output of this statement is as shown here:

```
mysql> SHOW TRIGGERS LIKE 'acc%\G
***** 1. row *****
  Trigger: ins_sum
    Event: INSERT
    Table: account
Statement: SET @sum = @sum + NEW.amount
  Timing: BEFORE
  Created: NULL
 sql_mode:
  Definer: myname@localhost
```

Note: When using a `LIKE` clause with `SHOW TRIGGERS`, the expression to be matched (`expr`) is compared with the name of the table on which the trigger is declared, and not with the name of the trigger:

```
mysql> SHOW TRIGGERS LIKE 'ins%';
Empty set (0.01 sec)
```

A brief explanation of the columns in the output of this statement is shown here:

- `Trigger`
The name of the trigger.
- `Event`
The event that causes trigger activation: one of '`INSERT`', '`UPDATE`', or '`DELETE`'.
- `Table`
The table for which the trigger is defined.
- `Statement`
The statement to be executed when the trigger is activated. This is the same as the text shown in the

`ACTION_STATEMENT` column of `INFORMATION_SCHEMA.TRIGGERS`.

- **Timing**
One of the two values 'BEFORE' or 'AFTER'.
- **Created**
Currently, the value of this column is always `NULL`.
- **sql_mode**
The SQL mode in effect when the trigger executes.
- **Definer**
The account that created the trigger.

See also [Section 22.16, “The INFORMATION_SCHEMA TRIGGERS Table”](#).

13.5.4.29. SHOW VARIABLES Syntax

```
SHOW [GLOBAL | SESSION] VARIABLES [LIKE 'pattern']
```

`SHOW VARIABLES` shows the values of MySQL system variables. This information also can be obtained using the `mysqladmin variables` command.

With the `GLOBAL` modifier, `SHOW VARIABLES` displays the values that are used for new connections to MySQL. With `SESSION`, it displays the values that are in effect for the current connection. If no modifier is present, the default is `SESSION`. `LOCAL` is a synonym for `SESSION`.

If the default system variable values are unsuitable, you can set them using command options when `mysqld` starts, and most can be changed at runtime with the `SET` statement. See [Section 5.2.4, “Using System Variables”](#), and [Section 13.5.3, “SET Syntax”](#).

Partial output is shown here. The list of names and values may be different for your server. [Section 5.2.3, “System Variables”](#), describes the meaning of each variable, and [Section 7.5.2, “Tuning Server Parameters”](#), provides information about tuning them.

```
mysql> SHOW VARIABLES;
```

Variable_name	Value
auto_increment_increment	1
auto_increment_offset	1
automatic_sp_privileges	ON
back_log	50
basedir	/home/jon/bin/mysql-5.1/
binlog_cache_size	32768
bulk_insert_buffer_size	8388608
character_set_client	latin1
character_set_connection	latin1
...	
max_user_connections	0
max_write_lock_count	4294967295
multi_range_count	256
mysam_data_pointer_size	6
mysam_max_sort_file_size	2147483647
mysam_recover_options	OFF
mysam_repair_threads	1
mysam_sort_buffer_size	8388608
ndb_autoincrement_prefetch_sz	32
ndb_cache_check_time	0
ndb_force_send	ON
...	

time_zone	SYSTEM
timed_mutexes	OFF
tmp_table_size	33554432
tmpdir	
transaction_alloc_block_size	8192
transaction_prealloc_size	4096
tx_isolation	REPEATABLE-READ
updatable_views_with_limit	YES
version	5.1.6-alpha-log
version_comment	Source distribution
version_compile_machine	i686
version_compile_os	suse-linux
wait_timeout	28800

With a [LIKE](#) clause, the statement displays only rows for those variables with names that match the pattern. To obtain the row for a specific variable, use a [LIKE](#) clause as shown:

```
SHOW VARIABLES LIKE 'max_join_size';
SHOW SESSION VARIABLES LIKE 'max_join_size';
```

To get a list of variables whose name match a pattern, use the `'%'` wildcard character in a [LIKE](#) clause:

```
SHOW VARIABLES LIKE '%size%';
SHOW GLOBAL VARIABLES LIKE '%size%';
```

Wildcard characters can be used in any position within the pattern to be matched. Strictly speaking, because `'_'` is a wildcard that matches any single character, you should escape it as `'_'` to match it literally. In practice, this is rarely necessary.

13.5.4.30. SHOW WARNINGS Syntax

```
SHOW WARNINGS [LIMIT [offset,] row_count]
SHOW COUNT(*) WARNINGS
```

[SHOW WARNINGS](#) shows the error, warning, and note messages that resulted from the last statement that generated messages, or nothing if the last statement that used a table generated no messages. A related statement, [SHOW ERRORS](#), shows only the errors. See [Section 13.5.4.14, “SHOW ERRORS Syntax”](#).

The list of messages is reset for each new statement that uses a table.

The [SHOW COUNT\(*\) WARNINGS](#) statement displays the total number of errors, warnings, and notes. You can also retrieve this number from the [warning_count](#) variable:

```
SHOW COUNT(*) WARNINGS;
SELECT @@warning_count;
```

The value of [warning_count](#) might be greater than the number of messages displayed by [SHOW WARNINGS](#) if the [max_error_count](#) system variable is set so low that not all messages are stored. An example shown later in this section demonstrates how this can happen.

The [LIMIT](#) clause has the same syntax as for the [SELECT](#) statement. See [Section 13.2.7, “SELECT Syntax”](#).

The MySQL server sends back the total number of errors, warnings, and notes resulting from the last statement. If you are using the C API, this value can be obtained by calling [mysql_warning_count\(\)](#). See [Section 24.2.3.71, “mysql_warning_count\(\)”](#).

Warnings are generated for statements such as [LOAD DATA INFILE](#) and DML statements such as [INSERT](#), [UPDATE](#), [CREATE TABLE](#), and [ALTER TABLE](#).

The following `DROP TABLE` statement results in a note:

```
mysql> DROP TABLE IF EXISTS no_such_table;
mysql> SHOW WARNINGS;
+-----+-----+-----+
| Level | Code | Message |
+-----+-----+-----+
| Note  | 1051 | Unknown table 'no_such_table' |
+-----+-----+-----+
```

Here is a simple example that shows a syntax warning for `CREATE TABLE` and conversion warnings for `INSERT`:

```
mysql> CREATE TABLE t1 (a TINYINT NOT NULL, b CHAR(4)) TYPE=MyISAM;
Query OK, 0 rows affected, 1 warning (0.00 sec)
mysql> SHOW WARNINGS\G
***** 1. row *****
Level: Warning
Code: 1287
Message: 'TYPE=storage_engine' is deprecated, use
        'ENGINE=storage_engine' instead
1 row in set (0.00 sec)

mysql> INSERT INTO t1 VALUES(10,'mysql'),(NULL,'test'),
-> (300,'Open Source');
Query OK, 3 rows affected, 4 warnings (0.01 sec)
Records: 3 Duplicates: 0 Warnings: 4

mysql> SHOW WARNINGS\G
***** 1. row *****
Level: Warning
Code: 1265
Message: Data truncated for column 'b' at row 1
***** 2. row *****
Level: Warning
Code: 1263
Message: Data truncated, NULL supplied to NOT NULL column 'a' at row 2
***** 3. row *****
Level: Warning
Code: 1264
Message: Data truncated, out of range for column 'a' at row 3
***** 4. row *****
Level: Warning
Code: 1265
Message: Data truncated for column 'b' at row 3
4 rows in set (0.00 sec)
```

The maximum number of error, warning, and note messages to store is controlled by the `max_error_count` system variable. By default, its value is 64. To change the number of messages you want stored, change the value of `max_error_count`. In the following example, the `ALTER TABLE` statement produces three warning messages, but only one is stored because `max_error_count` has been set to 1:

```
mysql> SHOW VARIABLES LIKE 'max_error_count';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| max_error_count | 64 |
+-----+-----+
1 row in set (0.00 sec)

mysql> SET max_error_count=1;
Query OK, 0 rows affected (0.00 sec)

mysql> ALTER TABLE t1 MODIFY b CHAR;
Query OK, 3 rows affected, 3 warnings (0.00 sec)
Records: 3 Duplicates: 0 Warnings: 3

mysql> SELECT @@warning_count;
+-----+
| @@warning_count |
+-----+
| 3 |
+-----+
```

```

1 row in set (0.01 sec)

mysql> SHOW WARNINGS;
+-----+-----+-----+
| Level | Code | Message                                     |
+-----+-----+-----+
| Warning | 1263 | Data truncated for column 'b' at row 1 |
+-----+-----+-----+
1 row in set (0.00 sec)

```

To disable warnings, set `max_error_count` to 0. In this case, `warning_count` still indicates how many warnings have occurred, but none of the messages are stored.

You can set the `SQL_NOTES` session variable to 0 to cause `Note`-level warnings not to be recorded.

13.5.5. Other Administrative Statements

13.5.5.1. `CACHE INDEX` Syntax

```

CACHE INDEX
  tbl_index_list [, tbl_index_list] ...
  IN key_cache_name

tbl_index_list:
  tbl_name [[INDEX|KEY] (index_name [, index_name] ...)]

```

The `CACHE INDEX` statement assigns table indexes to a specific key cache. It is used only for `MyISAM` tables.

The following statement assigns indexes from the tables `t1`, `t2`, and `t3` to the key cache named `hot_cache`:

```

mysql> CACHE INDEX t1, t2, t3 IN hot_cache;
+-----+-----+-----+-----+
| Table | Op                | Msg_type | Msg_text |
+-----+-----+-----+-----+
| test.t1 | assign_to_keycache | status   | OK       |
| test.t2 | assign_to_keycache | status   | OK       |
| test.t3 | assign_to_keycache | status   | OK       |
+-----+-----+-----+-----+

```

The syntax of `CACHE INDEX` enables you to specify that only particular indexes from a table should be assigned to the cache. The current implementation assigns all the table's indexes to the cache, so there is no reason to specify anything other than the table name.

The key cache referred to in a `CACHE INDEX` statement can be created by setting its size with a parameter setting statement or in the server parameter settings. For example:

```

mysql> SET GLOBAL keycache1.key_buffer_size=128*1024;

```

Key cache parameters can be accessed as members of a structured system variable. See [Section 5.2.4.1, “Structured System Variables”](#).

A key cache must exist before you can assign indexes to it:

```

mysql> CACHE INDEX t1 IN non_existent_cache;
ERROR 1284 (HY000): Unknown key cache 'non_existent_cache'

```

By default, table indexes are assigned to the main (default) key cache created at the server startup. When a key cache is destroyed, all indexes assigned to it become assigned to the default key cache again.

Index assignment affects the server globally: If one client assigns an index to a given cache, this cache is

used for all queries involving the index, no matter which client issues the queries.

13.5.5.2. FLUSH Syntax

```
FLUSH [LOCAL | NO_WRITE_TO_BINLOG] flush_option [, flush_option] ...
```

The **FLUSH** statement clears or reloads various internal caches used by MySQL. To execute **FLUSH**, you must have the **RELOAD** privilege.

The **RESET** statement is similar to **FLUSH**. See [Section 13.5.5.5, “RESET Syntax”](#).

flush_option can be any of the following:

- **HOSTS**

Empties the host cache tables. You should flush the host tables if some of your hosts change IP number or if you get the error message `Host 'host_name' is blocked`. When more than `max_connect_errors` errors occur successively for a given host while connecting to the MySQL server, MySQL assumes that something is wrong and blocks the host from further connection requests. Flushing the host tables allows the host to attempt to connect again. See [Section A.2.5, “Host 'host_name' is blocked”](#). You can start `mysqld` with `-max_connect_errors=999999999` to avoid this error message.

- **DES_KEY_FILE**

Reloads the DES keys from the file that was specified with the `--des-key-file` option at server startup time.

- **LOGS**

Closes and reopens all log files. If binary logging is enabled, the sequence number of the binary log file is incremented by one relative to the previous file. On Unix, this is the same thing as sending a `SIGHUP` signal to the `mysqld` server (except on some Mac OS X 10.3 versions where `mysqld` ignores `SIGHUP` and `SIGQUIT`).

If the server was started with the `--log-error` option, **FLUSH LOGS** causes the error log is renamed with a suffix of `-old` and `mysqld` creates a new empty log file. No renaming occurs if the `--log-error` option was not given.

- **MASTER (DEPRECATED)**. Deletes all binary logs, resets the binary log index file and creates a new binary log. Deprecated in favor of **RESET MASTER**, supported for backwards compatibility only. See [Section 13.6.1.2, “RESET MASTER Syntax”](#).

- **PRIVILEGES**

Reloads the privileges from the grant tables in the `mysql` database.

- **QUERY CACHE**

Defragment the query cache to better utilize its memory. **FLUSH QUERY CACHE** does not remove any queries from the cache, unlike **RESET QUERY CACHE**.

- **SLAVE (DEPRECATED)**. Resets all replication slave parameters, including relay log files and replication position in the master's binary logs. Deprecated in favour of **RESET SLAVE**, supported for backwards compatibility only. See [Section 13.6.2.5, “RESET SLAVE Syntax”](#).

- **STATUS**

Resets most status variables to zero. This is something you should use only when debugging a query. See [Section 1.8, “How to Report Bugs or Problems”](#).

- `{TABLE | TABLES} [tbl_name [, tbl_name] ...]`

When no tables are named, closes all open tables and forces all tables in use to be closed. This also flushes the query cache. With one or more table names, flushes only the given tables. `FLUSH TABLES` also removes all query results from the query cache, like the `RESET QUERY CACHE` statement.

- `TABLES WITH READ LOCK`

Closes all open tables and locks all tables for all databases with a read lock until you execute `UNLOCK TABLES`. This is very convenient way to get backups if you have a filesystem such as Veritas that can take snapshots in time.

- `USER_RESOURCES`

Resets all per-hour user resources to zero. This enables clients that have reached their hourly connection, query, or update limits to resume activity immediately. `FLUSH USER_RESOURCES` does not apply to the limit on maximum simultaneous connections. See [Section 13.5.1.3, “GRANT Syntax”](#).

`FLUSH` statements are written to the binary log unless the optional `NO_WRITE_TO_BINLOG` keyword (or its alias `LOCAL`) is used. This is done so that `FLUSH` statements used on a MySQL server acting as a replication master will be replicated by default to the replication slave.

Note: `FLUSH LOGS`, `FLUSH MASTER`, `FLUSH SLAVE`, and `FLUSH TABLES WITH READ LOCK` are not logged in any case because they would cause problems if replicated to a slave.

You can also access some of these statements with the `mysqladmin` utility, using the `flush-hosts`, `flush-logs`, `flush-privileges`, `flush-status`, or `flush-tables` commands.

Note: It is not possible in MySQL 5.1 to issue `FLUSH` statements within stored functions or triggers. However, you may use `FLUSH` in stored procedures, so long as these are not called from stored functions or triggers. See [Section 1.1, “Restrictions on Stored Routines and Triggers”](#).

See also [Section 13.5.5.5, “RESET Syntax”](#), for information about how the `RESET` statement is used with replication.

13.5.5.3. KILL Syntax

```
KILL [CONNECTION | QUERY] thread_id
```

Each connection to `mysqld` runs in a separate thread. You can see which threads are running with the `SHOW PROCESSLIST` statement and kill a thread with the `KILL thread_id` statement.

`KILL` allows the optional `CONNECTION` or `QUERY` modifier:

- `KILL CONNECTION` is the same as `KILL` with no modifier: It terminates the connection associated with the given *thread_id*.
- `KILL QUERY` terminates the statement that the connection is currently executing, but leaves the connection itself intact.

If you have the `PROCESS` privilege, you can see all threads. If you have the `SUPER` privilege, you can

kill all threads and statements. Otherwise, you can see and kill only your own threads and statements.

You can also use the `mysqladmin processlist` and `mysqladmin kill` commands to examine and kill threads.

Note: You cannot use `KILL` with the Embedded MySQL Server library, because the embedded server merely runs inside the threads of the host application. It does not create any connection threads of its own.

When you use `KILL`, a thread-specific kill flag is set for the thread. In most cases, it might take some time for the thread to die, because the kill flag is checked only at specific intervals:

- In `SELECT`, `ORDER BY` and `GROUP BY` loops, the flag is checked after reading a block of rows. If the kill flag is set, the statement is aborted.
- During `ALTER TABLE`, the kill flag is checked before each block of rows are read from the original table. If the kill flag was set, the statement is aborted and the temporary table is deleted.
- During `UPDATE` or `DELETE` operations, the kill flag is checked after each block read and after each updated or deleted row. If the kill flag is set, the statement is aborted. Note that if you are not using transactions, the changes are not rolled back.
- `GET_LOCK()` aborts and returns `NULL`.
- An `INSERT DELAYED` thread quickly flushes (inserts) all rows it has in memory and then terminates.
- If the thread is in the table lock handler (state: `Locked`), the table lock is quickly aborted.
- If the thread is waiting for free disk space in a write call, the write is aborted with a “disk full” error message.
- **Warning:** Killing a `REPAIR TABLE` or `OPTIMIZE TABLE` operation on a `MyISAM` table results in a table that is corrupted and unusable. Any reads or writes to such a table fail until you optimize or repair it again (without interruption).

13.5.5.4. LOAD INDEX INTO CACHE Syntax

```
LOAD INDEX INTO CACHE
  tbl_index_list [, tbl_index_list] ...

tbl_index_list:
  tbl_name
  [[INDEX|KEY] (index_name[, index_name] ...)]
  [IGNORE LEAVES]
```

The `LOAD INDEX INTO CACHE` statement preloads a table index into the key cache to which it has been assigned by an explicit `CACHE INDEX` statement, or into the default key cache otherwise. `LOAD INDEX INTO CACHE` is used only for `MyISAM` tables.

The `IGNORE LEAVES` modifier causes only blocks for the non-leaf nodes of the index to be preloaded.

The following statement preloads nodes (index blocks) of indexes for the tables `t1` and `t2`:

```
mysql> LOAD INDEX INTO CACHE t1, t2 IGNORE LEAVES;
+-----+-----+-----+-----+
| Table  | Op          | Msg_type | Msg_text |
+-----+-----+-----+-----+
| test.t1 | preload_keys | status   | OK       |
| test.t2 | preload_keys | status   | OK       |
+-----+-----+-----+-----+
```

This statement preloads all index blocks from `t1`. It preloads only blocks for the non-leaf nodes from `t2`.

The syntax of `LOAD INDEX INTO CACHE` enables you to specify that only particular indexes from a table should be preloaded. The current implementation preloads all the table's indexes into the cache, so there is no reason to specify anything other than the table name.

13.5.5.5. RESET Syntax

```
RESET reset_option [, reset_option] ...
```

The `RESET` statement is used to clear the state of various server operations. You must have the `RELOAD` privilege to execute `RESET`.

`RESET` acts as a stronger version of the `FLUSH` statement. See [Section 13.5.5.2, “FLUSH Syntax”](#).

reset_option can be any of the following:

- `MASTER`

Deletes all binary logs listed in the index file, resets the binary log index file to be empty, and creates a new binary log file. (Known as `FLUSH MASTER` in versions of MySQL before 3.23.26.) See [Section 13.6.1, “SQL Statements for Controlling Master Servers”](#).

- `QUERY CACHE`

Removes all query results from the query cache.

- `SLAVE`

Makes the slave forget its replication position in the master binary logs. Also resets the relay log by deleting any existing relay log files and beginning a new one. (Known as `FLUSH SLAVE` in versions of MySQL before 3.23.26.) See [Section 13.6.2, “SQL Statements for Controlling Slave Servers”](#).

13.6. Replication Statements

This section describes SQL statements related to replication. One group of statements is used for controlling master servers. The other is used for controlling slave servers.

13.6.1. SQL Statements for Controlling Master Servers

Replication can be controlled through the SQL interface. This section discusses statements for managing master replication servers. [Section 13.6.2, “SQL Statements for Controlling Slave Servers”](#), discusses statements for managing slave servers.

13.6.1.1. PURGE MASTER LOGS Syntax

```
PURGE {MASTER | BINARY} LOGS TO 'log_name'
PURGE {MASTER | BINARY} LOGS BEFORE 'date'
```

Deletes all the binary logs listed in the log index prior to the specified log or date. The logs also are removed from the list recorded in the log index file, so that the given log becomes the first.

Example:

```
PURGE MASTER LOGS TO 'mysql-bin.010';
PURGE MASTER LOGS BEFORE '2003-04-02 22:46:26';
```

The `BEFORE` variant's *date* argument can be in `'YYYY-MM-DD hh:mm:ss'` format. `MASTER` and `BINARY` are synonyms.

This statement is safe to run while slaves are replicating. You do not need to stop them. If you have an active slave that currently is reading one of the logs you are trying to delete, this statement does nothing and fails with an error. However, if a slave is dormant and you happen to purge one of the logs it has yet to read, the slave will be unable to replicate after it comes up.

To safely purge logs, follow this procedure:

1. On each slave server, use `SHOW SLAVE STATUS` to check which log it is reading.
2. Obtain a listing of the binary logs on the master server with `SHOW BINARY LOGS`.
3. Determine the earliest log among all the slaves. This is the target log. If all the slaves are up to date, this is the last log on the list.
4. Make a backup of all the logs you are about to delete. (This step is optional, but always advisable.)
5. Purge all logs up to but not including the target log.

You can also set the `expire_logs_days` system variable to expire binary log files automatically after a given number of days (see [Section 5.2.3, “System Variables”](#)). If you are using replication, you should set the variable no lower than the maximum number of days your slaves might lag behind the master.

13.6.1.2. RESET MASTER Syntax

```
RESET MASTER
```

Deletes all binary logs listed in the index file, resets the binary log index file to be empty, and creates a new binary log file.

13.6.1.3. SET SQL_LOG_BIN Syntax

```
SET SQL_LOG_BIN = {0|1}
```

Disables or enables binary logging for the current connection (`SQL_LOG_BIN` is a session variable) if the client has the `SUPER` privilege. The statement is refused with an error if the client does not have that privilege.

13.6.1.4. SHOW BINLOG EVENTS Syntax

```
SHOW BINLOG EVENTS
  [IN 'log_name'] [FROM pos] [LIMIT [offset,] row_count]
```

Shows the events in the binary log. If you do not specify `'log_name'`, the first binary log is displayed.

The `LIMIT` clause has the same syntax as for the `SELECT` statement. See [Section 13.2.7, “SELECT](#)

Syntax”.

Note: Issuing a `SHOW BINLOG EVENTS` with no `LIMIT` clause could start a very time- and resource-consuming process because the server returns to the client the complete contents of the binary log (which includes all statements executed by the server that modify data). As an alternative to `SHOW BINLOG EVENTS`, use the `mysqlbinlog` utility to save the binary log to a text file for later examination and analysis. See [Section 8.9, “mysqlbinlog — Utility for Processing Binary Log Files”](#).

13.6.1.5. SHOW BINARY LOGS Syntax

```
SHOW BINARY LOGS
SHOW MASTER LOGS
```

Lists the binary log files on the server. This statement is used as part of the procedure described in [Section 13.6.1.1, “PURGE MASTER LOGS Syntax”](#), that shows how to determine which logs can be purged.

```
mysql> SHOW BINARY LOGS;
+-----+-----+
| Log_name | File_size |
+-----+-----+
| binlog.000015 | 724935 |
| binlog.000016 | 733481 |
+-----+-----+
```

`SHOW MASTER LOGS` is equivalent to `SHOW BINARY LOGS`.

13.6.1.6. SHOW MASTER STATUS Syntax

```
SHOW MASTER STATUS
```

Provides status information about the binary log files of the master. Example:

```
mysql > SHOW MASTER STATUS;
+-----+-----+-----+-----+
| File | Position | Binlog_Do_DB | Binlog_Ignore_DB |
+-----+-----+-----+-----+
| mysql-bin.003 | 73 | test | manual,mysql |
+-----+-----+-----+-----+
```

13.6.1.7. SHOW SLAVE HOSTS Syntax

```
SHOW SLAVE HOSTS
```

Displays a list of replication slaves currently registered with the master. Only slaves started with the `--report-host=slave_name` option are visible in this list.

The list is displayed on any server (not just the master server). The output looks like this:

```
mysql> SHOW SLAVE HOSTS;
+-----+-----+-----+-----+
| Server_id | Host | Port | Master_id |
+-----+-----+-----+-----+
| 192168010 | iconnect2 | 3306 | 192168011 |
| 1921680101 | athena | 3306 | 192168011 |
+-----+-----+-----+-----+
```

- `Server_id`: The unique server ID of the slave server, as configured in the server's option file, or on the command line with `--server-id=value` .

- **Host**: The host name of the slave server, as configured in the server's option file, or on the command line with `--report-host=value`. Note that this can differ from the machine name as configured in the operating system.
- **Port**: The port the slave server is listening on.
- **Master_id**: The unique server ID of the master server that the slave server is replicating from.

Some MySQL versions report another variable, `Rpl_recovery_rank`. This variable was never used, and was eventually removed.

13.6.2. SQL Statements for Controlling Slave Servers

Replication can be controlled through the SQL interface. This section discusses statements for managing slave replication servers. Section 13.6.1, “SQL Statements for Controlling Master Servers”, discusses statements for managing master servers.

13.6.2.1. CHANGE MASTER TO Syntax

```
CHANGE MASTER TO master_def [, master_def] ...
```

```
master_def:
  MASTER_HOST = 'host_name'
  MASTER_USER = 'user_name'
  MASTER_PASSWORD = 'password'
  MASTER_PORT = port_num
  MASTER_CONNECT_RETRY = count
  MASTER_LOG_FILE = 'master_log_name'
  MASTER_LOG_POS = master_log_pos
  RELAY_LOG_FILE = 'relay_log_name'
  RELAY_LOG_POS = relay_log_pos
  MASTER_SSL = {0|1}
  MASTER_SSL_CA = 'ca_file_name'
  MASTER_SSL_CAPATH = 'ca_directory_name'
  MASTER_SSL_CERT = 'cert_file_name'
  MASTER_SSL_KEY = 'key_file_name'
  MASTER_SSL_CIPHER = 'cipher_list'
```

`CHANGE MASTER TO` changes the parameters that the slave server uses for connecting to and communicating with the master server. It also updates the contents of the `master.info` and `relay-log.info` files.

`MASTER_USER`, `MASTER_PASSWORD`, `MASTER_SSL`, `MASTER_SSL_CA`, `MASTER_SSL_CAPATH`, `MASTER_SSL_CERT`, `MASTER_SSL_KEY`, and `MASTER_SSL_CIPHER` provide information to the slave about how to connect to its master.

The SSL options (`MASTER_SSL`, `MASTER_SSL_CA`, `MASTER_SSL_CAPATH`, `MASTER_SSL_CERT`, `MASTER_SSL_KEY`, and `MASTER_SSL_CIPHER`) can be changed even on slaves that are compiled without SSL support. They are saved to the `master.info` file, but are ignored unless you use a server that has SSL support enabled.

If you don't specify a given parameter, it keeps its old value, except as indicated in the following discussion. For example, if the password to connect to your MySQL master has changed, you just need to issue these statements to tell the slave about the new password:

```
STOP SLAVE; -- if replication was running
CHANGE MASTER TO MASTER_PASSWORD='new3cret';
START SLAVE; -- if you want to restart replication
```

There is no need to specify the parameters that do not change (host, port, user, and so forth).

`MASTER_HOST` and `MASTER_PORT` are the hostname (or IP address) of the master host and its TCP/IP

port. Note that if `MASTER_HOST` is equal to `localhost`, then, like in other parts of MySQL, the port number might be ignored (if Unix socket files can be used, for example).

If you specify `MASTER_HOST` or `MASTER_PORT`, the slave assumes that the master server is different from before (even if you specify a host or port value that is the same as the current value.) In this case, the old values for the master binary log name and position are considered no longer applicable, so if you do not specify `MASTER_LOG_FILE` and `MASTER_LOG_POS` in the statement, `MASTER_LOG_FILE=''` and `MASTER_LOG_POS=4` are silently appended to it.

`MASTER_LOG_FILE` and `MASTER_LOG_POS` are the coordinates at which the slave I/O thread should begin reading from the master the next time the thread starts. If you specify either of them, you cannot specify `RELAY_LOG_FILE` or `RELAY_LOG_POS`. If neither of `MASTER_LOG_FILE` or `MASTER_LOG_POS` are specified, the slave uses the last coordinates of the *slave SQL thread* before `CHANGE MASTER` was issued. This ensures that there is no discontinuity in replication, even if the slave SQL thread was late compared to the slave I/O thread, when you merely want to change, say, the password to use.

`CHANGE MASTER` deletes all relay log files and starts a new one, unless you specify `RELAY_LOG_FILE` or `RELAY_LOG_POS`. In that case, relay logs are kept; the `relay_log_purge` global variable is set silently to 0.

`CHANGE MASTER` is useful for setting up a slave when you have the snapshot of the master and have recorded the log and the offset corresponding to it. After loading the snapshot into the slave, you can run `CHANGE MASTER TO MASTER_LOG_FILE='log_name_on_master', MASTER_LOG_POS=log_offset_on_master` on the slave.

The following example changes the master and master's binary log coordinates. This is used when you want to set up the slave to replicate the master:

```
CHANGE MASTER TO
  MASTER_HOST='master2.mycompany.com',
  MASTER_USER='replication',
  MASTER_PASSWORD='bigs3cret',
  MASTER_PORT=3306,
  MASTER_LOG_FILE='master2-bin.001',
  MASTER_LOG_POS=4,
  MASTER_CONNECT_RETRY=10;
```

The next example shows an operation that is less frequently employed. It is used when the slave has relay logs that you want it to execute again for some reason. To do this, the master need not be reachable. You need only use `CHANGE MASTER TO` and start the SQL thread (`START SLAVE SQL_THREAD`):

```
CHANGE MASTER TO
  RELAY_LOG_FILE='slave-relay-bin.006',
  RELAY_LOG_POS=4025;
```

You can even use the second operation in a non-replication setup with a standalone, non-slave server for recovery following a crash. Suppose that your server has crashed and you have restored a backup. You want to replay the server's own binary logs (not relay logs, but regular binary logs), named (for example) `myhost-bin.*`. First, make a backup copy of these binary logs in some safe place, in case you don't exactly follow the procedure below and accidentally have the server purge the binary logs. Use `SET GLOBAL relay_log_purge=0` for additional safety. Then start the server without the `--log-bin` option. Instead, use the `--replicate-same-server-id`, `--relay-log=myhost-bin` (to make the server believe that these regular binary logs are relay logs) and `--skip-slave-start` options. After the server starts, issue these statements:

```
CHANGE MASTER TO
  RELAY_LOG_FILE='myhost-bin.153',
  RELAY_LOG_POS=410,
  MASTER_HOST='some_dummy_string';
START SLAVE SQL_THREAD;
```

The server reads and executes its own binary logs, thus achieving crash recovery. Once the recovery is finished, run `STOP SLAVE`, shut down the server, delete the `master.info` and `relay-log.info` files, and restart the server with its original options.

Specifying the `MASTER_HOST` option (even with a dummy value) is required to make the server think it is a slave.

13.6.2.2. LOAD DATA FROM MASTER Syntax

```
LOAD DATA FROM MASTER
```

This feature is deprecated. We recommend not using it anymore. It is subject to removal in a future version of MySQL.

Since the current implementation of `LOAD DATA FROM MASTER` and `LOAD TABLE FROM MASTER` is very limited, these statements are deprecated in versions 4.1 of MySQL and above. We will introduce a more advanced technique (called “online backup”) in a future version. That technique will have the additional advantage of working with more storage engines.

For MySQL 5.1 and earlier, the recommended alternative solution to using `LOAD DATA FROM MASTER` or `LOAD TABLE FROM MASTER` is using `mysqldump` or `mysqlhotcopy`. The latter requires Perl and two Perl modules (`DBI` and `DBD:mysql`) and works for `MyISAM` and `ARCHIVE` tables only. With `mysqldump`, you can create SQL dumps on the master and pipe (or copy) these to a `mysql` client on the slave. This has the advantage of working for all storage engines, but can be quite slow, since it works using `SELECT`.

This statement takes a snapshot of the master and copies it to the slave. It updates the values of `MASTER_LOG_FILE` and `MASTER_LOG_POS` so that the slave starts replicating from the correct position. Any table and database exclusion rules specified with the `--replicate-*-do-*` and `--replicate-*-ignore-*` options are honored. `--replicate-rewrite-db` is *not* taken into account because a user could use this option to set up a non-unique mapping such as `--replicate-rewrite-db="db1->db3"` and `--replicate-rewrite-db="db2->db3"`, which would confuse the slave when loading tables from the master.

Use of this statement is subject to the following conditions:

- It works only for `MyISAM` tables. Attempting to load a non-`MyISAM` table results in the following error:

```
ERROR 1189 (08S01): Net error reading from master
```

- It acquires a global read lock on the master while taking the snapshot, which prevents updates on the master during the load operation.

If you are loading large tables, you might have to increase the values of `net_read_timeout` and `net_write_timeout` on both the master and slave servers. See [Section 5.2.3, “System Variables”](#).

Note that `LOAD DATA FROM MASTER` does *not* copy any tables from the `mysql` database. This makes it easy to have different users and privileges on the master and the slave.

To use `LOAD DATA FROM MASTER`, the replication account that is used to connect to the master must have the `RELOAD` and `SUPER` privileges on the master and the `SELECT` privilege for all master tables you want to load. All master tables for which the user does not have the `SELECT` privilege are ignored by `LOAD DATA FROM MASTER`. This is because the master hides them from the user: `LOAD DATA FROM MASTER` calls `SHOW DATABASES` to know the master databases to load, but `SHOW DATABASES` returns only databases for which the user has some privilege. See [Section 13.5.4.11, “SHOW](#)

[DATABASES Syntax](#)". On the slave side, the user that issues `LOAD DATA FROM MASTER` must have privileges for dropping and creating the databases and tables that are copied.

13.6.2.3. `LOAD TABLE tbl_name FROM MASTER` Syntax

```
LOAD TABLE tbl_name FROM MASTER
```

This feature is deprecated. We recommend not using it anymore. It is subject to removal in a future version of MySQL.

Since the current implementation of `LOAD DATA FROM MASTER` and `LOAD TABLE FROM MASTER` is very limited, these statements are deprecated in versions 4.1 of MySQL and above. We will introduce a more advanced technique (called "online backup") in a future version. That technique will have the additional advantage of working with more storage engines.

For MySQL 5.1 and earlier, the recommended alternative solution to using `LOAD DATA FROM MASTER` or `LOAD TABLE FROM MASTER` is using `mysqldump` or `mysqlhotcopy`. The latter requires Perl and two Perl modules (`DBI` and `DBD:mysql`) and works for `MyISAM` and `ARCHIVE` tables only. With `mysqldump`, you can create SQL dumps on the master and pipe (or copy) these to a `mysql` client on the slave. This has the advantage of working for all storage engines, but can be quite slow, since it works using `SELECT`.

Transfers a copy of the table from the master to the slave. This statement is implemented mainly debugging `LOAD DATA FROM MASTER` operations. To use `LOAD TABLE`, the account used for connecting to the master server must have the `RELOAD` and `SUPER` privileges on the master and the `SELECT` privilege for the master table to load. On the slave side, the user that issues `LOAD TABLE FROM MASTER` must have privileges for dropping and creating the table.

The conditions for `LOAD DATA FROM MASTER` apply here as well. For example, `LOAD TABLE FROM MASTER` works only for `MyISAM` tables. The timeout notes for `LOAD DATA FROM MASTER` apply as well.

13.6.2.4. `MASTER_POS_WAIT()` Syntax

```
SELECT MASTER_POS_WAIT('master_log_file', master_log_pos)
```

This is actually a function, not a statement. It is used to ensure that the slave has read and executed events up to a given position in the master's binary log. See [Section 12.10.4, "Miscellaneous Functions"](#), for a full description.

13.6.2.5. `RESET SLAVE` Syntax

```
RESET SLAVE
```

`RESET SLAVE` makes the slave forget its replication position in the master's binary logs. This statement is meant to be used for a clean start: It deletes the `master.info` and `relay-log.info` files, all the relay logs, and starts a new relay log.

Note: All relay logs are deleted, even if they have not been completely executed by the slave SQL thread. (This is a condition likely to exist on a replication slave if you have issued a `STOP SLAVE` statement or if the slave is highly loaded.)

Connection information stored in the `master.info` file is immediately reset using any values specified in the corresponding startup options. This information includes values such as master host, master port, master user, and master password. If the slave SQL thread was in the middle of replicating temporary tables when it was stopped, and `RESET SLAVE` is issued, these replicated temporary tables are deleted on the slave.

13.6.2.6. SET GLOBAL SQL_SLAVE_SKIP_COUNTER Syntax

```
SET GLOBAL SQL_SLAVE_SKIP_COUNTER = N
```

This statement skips the next *N* events from the master. This is useful for recovering from replication stops caused by a statement.

This statement is valid only when the slave thread is not running. Otherwise, it produces an error.

13.6.2.7. SHOW SLAVE STATUS Syntax

```
SHOW SLAVE STATUS
```

This statement provides status information on essential parameters of the slave threads. If you issue this statement using the `mysql` client, you can use a `\G` statement terminator rather than a semicolon to obtain a more readable vertical layout:

```
mysql> SHOW SLAVE STATUS\G
***** 1. row *****
Slave_IO_State: Waiting for master to send event
Master_Host: localhost
Master_User: root
Master_Port: 3306
Connect_Retry: 3
Master_Log_File: gbichot-bin.005
Read_Master_Log_Pos: 79
Relay_Log_File: gbichot-relay-bin.005
Relay_Log_Pos: 548
Relay_Master_Log_File: gbichot-bin.005
Slave_IO_Running: Yes
Slave_SQL_Running: Yes
Replicate_Do_DB:
Replicate_Ignore_DB:
Last_Errno: 0
Last_Error:
Skip_Counter: 0
Exec_Master_Log_Pos: 79
Relay_Log_Space: 552
Until_Condition: None
Until_Log_File:
Until_Log_Pos: 0
Master_SSL_Allowed: No
Master_SSL_CA_File:
Master_SSL_CA_Path:
Master_SSL_Cert:
Master_SSL_Cipher:
Master_SSL_Key:
Seconds_Behind_Master: 8
```

`SHOW SLAVE STATUS` returns the following fields:

- `Slave_IO_State`

A copy of the `State` field of the output of `SHOW PROCESSLIST` for the slave I/O thread. This tells you what the thread is doing: trying to connect to the master, waiting for events from the master, reconnecting to the master, and so on. Possible states are listed in [Section 6.4, “Replication Implementation Details”](#). It is necessary to check this field for older versions of MySQL which allowed the thread to continue running while unsuccessfully trying to connect to the master. If it is running, there is no problem; if it is not, you can find the error in the `Last_Error` field (described below).

- `Master_Host`

The current master host.

- `Master_User`
The current user used to connect to the master.
- `Master_Port`
The current master port.
- `Connect_Retry`
The current value of the `--master-connect-retry` option.
- `Master_Log_File`
The name of the master binary log file from which the I/O thread is currently reading.
- `Read_Master_Log_Pos`
The position up to which the I/O thread has read in the current master binary log.
- `Relay_Log_File`
The name of the relay log file from which the SQL thread is currently reading and executing.
- `Relay_Log_Pos`
The position up to which the SQL thread has read and executed in the current relay log.
- `Relay_Master_Log_File`
The name of the master binary log file containing the most recent event executed by the SQL thread.
- `Slave_IO_Running`
Whether the I/O thread is started and has connected successfully to the master. For older versions of MySQL (prior to 4.1.14 and 5.0.12) `Slave_IO_Running` is `YES` if the I/O thread is started, even if the slave hasn't connected to the master yet.
- `Slave_SQL_Running`
Whether the SQL thread is started.
- `Replicate_Do_DB, Replicate_Ignore_DB`
The lists of databases that were specified with the `--replicate-do-db` and `--replicate-ignore-db` options, if any.
- `Replicate_Do_Table, Replicate_Ignore_Table, Replicate_Wild_Do_Table, Replicate_Wild_Ignore_Table`
The lists of tables that were specified with the `--replicate-do-table`, `--replicate-ignore-table`, `--replicate-wild-do-table`, and `--replicate-wild-ignore-table` options, if any.
- `Last_Errno, Last_Error`
The error number and error message returned by the most recently executed query. An error number of 0 and message of the empty string mean “no error.” If the `Last_Error` value is not empty, it also appears as a message in the slave's error log. For example:

```
Last_Errno: 1051
Last_Error: error 'Unknown table 'z'' on query 'drop table z'
```

The message indicates that the table `z` existed on the master and was dropped there, but it did not exist on the slave, so `DROP TABLE` failed on the slave. (This might occur, for example, if you forget to copy the table to the slave when setting up replication.)

- `Skip_Counter`

The most recently used value for `SQL_SLAVE_SKIP_COUNTER`.

- `Exec_Master_Log_Pos`

The position of the last event executed by the SQL thread from the master's binary log (`Relay_Master_Log_File`). (`Relay_Master_Log_File`, `Exec_Master_Log_Pos`) in the master's binary log corresponds to (`Relay_Log_File`, `Relay_Log_Pos`) in the relay log.

- `Relay_Log_Space`

The total combined size of all existing relay logs.

- `Until_Condition`, `Until_Log_File`, `Until_Log_Pos`

The values specified in the `UNTIL` clause of the `START SLAVE` statement.

`Until_Condition` has these values:

- `None` if no `UNTIL` clause was specified
- `Master` if the slave is reading until a given position in the master's binary logs
- `Relay` if the slave is reading until a given position in its relay logs

`Until_Log_File` and `Until_Log_Pos` indicate the log filename and position values that define the point at which the SQL thread stops executing.

- `Master_SSL_Allowed`, `Master_SSL_CA_File`, `Master_SSL_CA_Path`, `Master_SSL_Cert`, `Master_SSL_Cipher`, `Master_SSL_Key`

These fields show the SSL parameters used by the slave to connect to the master, if any.

`Master_SSL_Allowed` has these values:

- `Yes` if an SSL connection to the master is permitted
- `No` if an SSL connection to the master is not permitted
- `Ignored` if an SSL connection is permitted but the slave server does not have SSL support enabled

The values of the other SSL-related fields correspond to the values of the `--master-ca`, `--master-capath`, `--master-cert`, `--master-cipher`, and `--master-key` options.

- `Seconds_Behind_Master`

This field is an indication of how “late” the slave is:

- When the slave SQL thread is actively running (processing updates), this field is the number of seconds that have elapsed since the timestamp of the most recent event on the master executed

by that thread.

- When the SQL thread has caught up to the slave I/O thread and goes idle waiting for more events from the I/O thread, this field is zero.

In essence, this field measures the time difference in seconds between the slave SQL thread and the slave I/O thread.

If the network connection between master and slave is fast, the slave I/O thread is very close to the master, so this field is a good approximation of how late the slave SQL thread is compared to the master. If the network is slow, this is *not* a good approximation; the slave SQL thread may quite often be caught up with the slow-reading slave I/O thread, so `Seconds_Behind_Master` often shows a value of 0, even if the I/O thread is late compared to the master. In other words, *this column is useful only for fast networks*.

This time difference computation works even though the master and slave do not have identical clocks (the clock difference is computed when the slave I/O thread starts, and assumed to remain constant from then on). `Seconds_Behind_Master` is `NULL` (which means “unknown”) if the slave SQL thread is not running, or if the slave I/O thread is not running or not connected to master. For example if the slave I/O thread is sleeping for the number of seconds given by the `--master-connect-retry` option before reconnecting, `NULL` is shown, as the slave cannot know what the master is doing, and so cannot say reliably how late it is.

This field has one limitation. The timestamp is preserved through replication, which means that, if a master M1 is itself a slave of M0, any event from M1's binlog which originates in replicating an event from M0's binlog has the timestamp of that event. This enables MySQL to replicate `TIMESTAMP` successfully. However, the drawback for `Seconds_Behind_Master` is that if M1 also receives direct updates from clients, the value randomly deviates, because sometimes the last M1's event is from M0 and sometimes it is the most recent timestamp from a direct update.

13.6.2.8. `START SLAVE` Syntax

```
START SLAVE [thread_type [, thread_type] ... ]
START SLAVE [SQL_THREAD] UNTIL
  MASTER_LOG_FILE = 'log_name', MASTER_LOG_POS = log_pos
START SLAVE [SQL_THREAD] UNTIL
  RELAY_LOG_FILE = 'log_name', RELAY_LOG_POS = log_pos

thread_type: IO_THREAD | SQL_THREAD
```

`START SLAVE` with no `thread_type` options starts both of the slave threads. The I/O thread reads queries from the master server and stores them in the relay log. The SQL thread reads the relay log and executes the queries. `START SLAVE` requires the `SUPER` privilege.

If `START SLAVE` succeeds in starting the slave threads, it returns without any error. However, even in that case, it might be that the slave threads start and then later stop (for example, because they do not manage to connect to the master or read its binary logs, or some other problem). `START SLAVE` does not warn you about this. You must check the slave's error log for error messages generated by the slave threads, or check that they are running satisfactorily with `SHOW SLAVE STATUS`.

You can add `IO_THREAD` and `SQL_THREAD` options to the statement to name which of the threads to start.

An `UNTIL` clause may be added to specify that the slave should start and run until the SQL thread reaches a given point in the master binary logs or in the slave relay logs. When the SQL thread reaches that point, it stops. If the `SQL_THREAD` option is specified in the statement, it starts only the SQL thread. Otherwise, it starts both slave threads. If the SQL thread is running, the `UNTIL` clause is ignored

and a warning is issued.

For an `UNTIL` clause, you must specify both a log filename and position. Do not mix master and relay log options.

Any `UNTIL` condition is reset by a subsequent `STOP SLAVE` statement, a `START SLAVE` statement that includes no `UNTIL` clause, or a server restart.

The `UNTIL` clause can be useful for debugging replication, or to cause replication to proceed until just before the point where you want to avoid having the slave replicate a statement. For example, if an unwise `DROP TABLE` statement was executed on the master, you can use `UNTIL` to tell the slave to execute up to that point but no farther. To find what the event is, use `mysqlbinlog` with the master logs or slave relay logs, or by using a `SHOW BINLOG EVENTS` statement.

If you are using `UNTIL` to have the slave process replicated queries in sections, it is recommended that you start the slave with the `--skip-slave-start` option to prevent the SQL thread from running when the slave server starts. It is probably best to use this option in an option file rather than on the command line, so that an unexpected server restart does not cause it to be forgotten.

The `SHOW SLAVE STATUS` statement includes output fields that display the current values of the `UNTIL` condition.

In old versions of MySQL (before 4.0.5), this statement was called `SLAVE START`. This usage is still accepted in MySQL 5.1 for backward compatibility, but is deprecated.

13.6.2.9. STOP SLAVE Syntax

```
STOP SLAVE [thread_type [, thread_type] ... ]
thread_type: IO_THREAD | SQL_THREAD
```

Stops the slave threads. `STOP SLAVE` requires the `SUPER` privilege.

Like `START SLAVE`, this statement may be used with the `IO_THREAD` and `SQL_THREAD` options to name the thread or threads to be stopped.

In old versions of MySQL (before 4.0.5), this statement was called `SLAVE STOP`. This usage is still accepted in MySQL 5.1 for backward compatibility, but is deprecated.

13.7. SQL Syntax for Prepared Statements

MySQL 5.1 provides support for server-side prepared statements. This support takes advantage of the efficient client/server binary protocol implemented in MySQL 4.1, provided that you use an appropriate client programming interface. Candidate interfaces include the MySQL C API client library (for C programs), MySQL Connector/J (for Java programs), and MySQL Connector/NET. For example, the C API provides a set of function calls that make up its prepared statement API. See [Section 24.2.4, “C API Prepared Statements”](#). Other language interfaces can provide support for prepared statements that use the binary protocol by linking in the C client library, one example being the `mysql_i` extension [http://php.net/mysql_i], available in PHP 5.0 and later.

An alternative SQL interface to prepared statements is available. This interface is not as efficient as using the binary protocol through a prepared statement API, but requires no programming because it is available directly at the SQL level:

- You can use it when no programming interface is available to you.
- You can use it from any program that allows you to send SQL statements to the server to be executed, such as the `mysql` client program.

- You can use it even if the client is using an old version of the client library. The only requirement is that you be able to connect to a server that is recent enough to support SQL syntax for prepared statements.

SQL syntax for prepared statements is intended to be used for situations such as these:

- You want to test how prepared statements work in your application before coding it.
- An application has problems executing prepared statements and you want to determine interactively what the problem is.
- You want to create a test case that describes a problem you are having with prepared statements, so that you can file a bug report.
- You need to use prepared statements but do not have access to a programming API that supports them.

SQL syntax for prepared statements is based on three SQL statements:

- `PREPARE stmt_name FROM preparable_stmt`

The `PREPARE` statement prepares a statement and assigns it a name, `stmt_name`, by which to refer to the statement later. Statement names are not case sensitive. `preparable_stmt` is either a string literal or a user variable that contains the text of the statement. The text must represent a single SQL statement, not multiple statements. Within the statement, ‘?’ characters can be used as parameter markers to indicate where data values are to be bound to the query later when you execute it. The ‘?’ characters should not be enclosed within quotes, even if you intend to bind them to string values. Parameter markers can be used only where data values should appear, not for SQL keywords, identifiers, and so forth.

If a prepared statement with the given name already exists, it is deallocated implicitly before the new statement is prepared. This means that if the new statement contains an error and cannot be prepared, an error is returned and no statement with the given name exists.

The scope of a prepared statement is the client session within which it is created. Other clients cannot see it.

- `EXECUTE stmt_name [USING @var_name [, @var_name] ...]`

After preparing a statement, you execute it with an `EXECUTE` statement that refers to the prepared statement name. If the prepared statement contains any parameter markers, you must supply a `USING` clause that lists user variables containing the values to be bound to the parameters. Parameter values can be supplied only by user variables, and the `USING` clause must name exactly as many variables as the number of parameter markers in the statement.

You can execute a given prepared statement multiple times, passing different variables to it or setting the variables to different values before each execution.

- `{DEALLOCATE | DROP} PREPARE stmt_name`

To deallocate a prepared statement, use the `DEALLOCATE PREPARE` statement. Attempting to execute a prepared statement after deallocating it results in an error.

If you terminate a client session without deallocating a previously prepared statement, the server deallocates it automatically.

The following SQL statements can be used in prepared statements: `CREATE TABLE`, `DELETE`, `DO`, `INSERT`, `REPLACE`, `SELECT`, `SET`, `UPDATE`, and most `SHOW` statements.

The following statements are supported as of MySQL 5.1.10:

```
ANALYZE TABLE
OPTIMIZE TABLE
REPAIR TABLE
```

The following statements are supported as of MySQL 5.1.12:

```
CACHE INDEX
CHANGE MASTER
CHECKSUM {TABLE | TABLES}
{CREATE | RENAME | DROP} DATABASE
{CREATE | RENAME | DROP} USER
FLUSH {TABLE | TABLES | TABLES WITH READ LOCK | HOSTS | PRIVILEGES
      | LOGS | STATUS | MASTER | SLAVE | DES_KEY_FILE | USER_RESOURCES}
GRANT
REVOKE
KILL
LOAD INDEX INTO CACHE
RESET {MASTER | SLAVE | QUERY CACHE}
SHOW BINLOG EVENTS
SHOW CREATE {PROCEDURE | FUNCTION | EVENT | TABLE | VIEW}
SHOW {AUTHORS | CONTRIBUTORS | WARNINGS | ERRORS}
SHOW {MASTER | BINARY} LOGS
SHOW {MASTER | SLAVE} STATUS
SLAVE {START | STOP}
INSTALL PLUGIN
UNINSTALL PLUGIN
```

Other statements are not yet supported.

The following examples show two equivalent ways of preparing a statement that computes the hypotenuse of a triangle given the lengths of the two sides.

The first example shows how to create a prepared statement by using a string literal to supply the text of the statement:

```
mysql> PREPARE stmt1 FROM 'SELECT SQRT(POW(?,2) + POW(?,2)) AS hypotenuse';
mysql> SET @a = 3;
mysql> SET @b = 4;
mysql> EXECUTE stmt1 USING @a, @b;
+-----+
| hypotenuse |
+-----+
|          5 |
+-----+
mysql> DEALLOCATE PREPARE stmt1;
```

The second example is similar, but supplies the text of the statement as a user variable:

```
mysql> SET @s = 'SELECT SQRT(POW(?,2) + POW(?,2)) AS hypotenuse';
mysql> PREPARE stmt2 FROM @s;
mysql> SET @a = 6;
mysql> SET @b = 8;
mysql> EXECUTE stmt2 USING @a, @b;
+-----+
| hypotenuse |
+-----+
|          10 |
+-----+
mysql> DEALLOCATE PREPARE stmt2;
```

Placeholders can be used for the arguments of the `LIMIT` clause when using prepared statements. See [Section 13.2.7, “SELECT Syntax”](#).

SQL syntax for prepared statements cannot be used in nested fashion. That is, a statement passed to `PREPARE` cannot itself be a `PREPARE`, `EXECUTE`, or `DEALLOCATE PREPARE` statement.

SQL syntax for prepared statements is distinct from using prepared statement API calls. For example, you cannot use the `mysql_stmt_prepare()` C API function to prepare a `PREPARE`, `EXECUTE`, or `DEALLOCATE PREPARE` statement.

SQL syntax for prepared statements can be used within stored procedures, but not in stored functions or triggers.

SQL syntax for prepared statements does not support multi-statements (that is, multiple statements within a single string separated by `;` characters).

Chapter 14. Storage Engines and Table Types

MySQL supports several storage engines that act as handlers for different table types. MySQL storage engines include both those that handle transaction-safe tables and those that handle non-transaction-safe tables:

With MySQL 5.1, MySQL AB has introduced a new pluggable storage engine architecture that allows storage engines to be loaded into and unloaded from a running MySQL server.

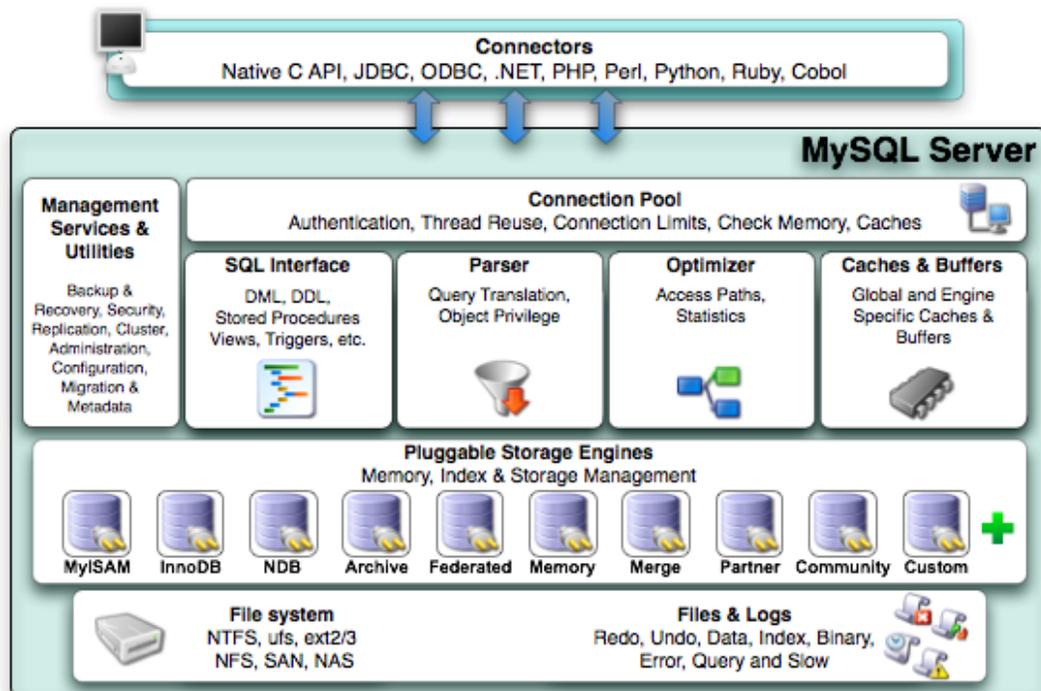

This chapter describes the pluggable storage engine architecture and described the array of storage engines that are available.

14.1. Overview of MySQL Storage Engine Architecture

The MySQL pluggable storage engine architecture allows a database professional to select a specialized storage engine for a particular application need while being completely shielded from the need to manage any specific application coding requirements. The MySQL server architecture isolates the application programmer and DBA from all of the low-level implementation details at the storage level, providing a consistent and easy application model and API. Thus, although there are different capabilities across different storage engines, the application is shielded from these differences.

The MySQL pluggable storage engine architecture has the structure shown in the following figure:

Figure 14.1. The MySQL pluggable storage engine architecture

The pluggable storage engine architecture provides a standard set of management and support services that are common among all underlying storage engines. The storage engines themselves are the components of the database server that actually perform actions on the underlying data that is maintained at the

physical server level.

This efficient and modular architecture provides huge benefits for those wishing to specifically target a particular application need — such as data warehousing, transaction processing, or high availability situations — while enjoying the advantage of utilizing a set of interfaces and services that are independent of any one storage engine.

The application programmer and DBA interact with the MySQL database through Connector APIs and service layers that are above the storage engines. If application changes bring about requirements that demand the underlying storage engine change, or that one or more additional storage engines be added to support new needs, no significant coding or process changes are required to make things work. The MySQL server architecture shields the application from the underlying complexity of the storage engine by presenting a consistent and easy-to-use API that applies across storage engines.

14.1.1. The Common Database Server Layer

A MySQL pluggable storage engine is the component in the MySQL database server that is responsible for performing the actual data I/O operations for a database as well as enabling and enforcing certain feature sets that target a specific application need. A major benefit of using specific storage engines is that you are only delivered the features needed for a particular application, and therefore you have less system overhead in the database, with the end result being more efficient and higher database performance. This is one of the reasons that MySQL has always been known to have such high performance, matching or beating proprietary monolithic databases in industry standard benchmarks.

From a technical perspective, what are some of the unique supporting infrastructure components that are in a storage engine? Some of the key feature differentiations include:

- *Concurrency* — some applications have more granular lock requirements (such as row-level locks) than others. Choosing the right locking strategy can reduce overhead and therefore improve overall performance. This area also includes support for capabilities such as multi-version concurrency control or “snapshot” read.
- *Transaction Support* — Not every application needs transactions, but for those that do, there are very well defined requirements such as ACID compliance and more.
- *Referential Integrity* — The need to have the server enforce relational database referential integrity through DDL defined foreign keys.
- *Physical Storage* — This involves everything from the overall page size for tables and indexes as well as the format used for storing data to physical disk.
- *Index Support* — Different application scenarios tend to benefit from different index strategies. Each storage engine generally has its own indexing methods, although some (such as B-tree indexes) are common to nearly all engines.
- *Memory Caches* — Different applications respond better to some memory caching strategies than others, so although some memory caches are common to all storage engines (such as those used for user connections or MySQL's high-speed Query Cache), others are uniquely defined only when a particular storage engine is put in play.
- *Performance Aids* — This includes multiple I/O threads for parallel operations, thread concurrency, database checkpointing, bulk insert handling, and more.
- *Miscellaneous Target Features* — This may include support for geospatial operations, security restrictions for certain data manipulation operations, and other similar features.

Each set of the pluggable storage engine infrastructure components are designed to offer a selective set of benefits for a particular application. Conversely, avoiding a set of component features helps reduce unnecessary overhead. It stands to reason that understanding a particular application's set of requirements and selecting the proper MySQL storage engine can have a dramatic impact on overall system efficiency and performance.

14.1.2. Pluggable Storage Engine Architecture

With MySQL 5.1, MySQL AB has introduced a new pluggable storage engine architecture that allows storage engines to be loaded into and unloaded from a running MySQL server.

14.1.2.1. Plugging in a Storage Engine

Before a storage engine can be used, the storage engine plugin shared library must be loaded into MySQL using the `INSTALL PLUGIN` statement. For example, if the `EXAMPLE` engine plugin is named `ha_example` and the shared library is named `ha_example.so`, you load it with the following statement:

```
INSTALL PLUGIN ha_example SONAME 'ha_example.so';
```

The shared library must be located in the MySQL server plugin directory, the location of which is given by the `plugin_dir` system variable.

14.1.2.2. Unplugging a Storage Engine

To unplug a storage engine, use the `UNINSTALL PLUGIN` statement:

```
UNINSTALL PLUGIN ha_example;
```

If you unplug a storage engine that is needed by existing tables, those tables become inaccessible, but will still be present on disk (where applicable). Ensure that there are no tables using a storage engine before you unplug the storage engine.

14.1.2.3. Security Implications of Pluggable Storage

To install a pluggable storage engine, the plugin file must be located in the MySQL plugin directory, and the user issuing the `INSTALL PLUGIN` statement must have `INSERT` privileges for the `mysql.plugin` table.

14.2. Supported Storage Engines

MySQL 5.1 supports the following storage engines:

- **MyISAM** — The default MySQL storage engine and the one that is used the most in Web, data warehousing, and other application environments. **MyISAM** is supported in all MySQL configurations, and is the default storage engine unless you have configured MySQL to use a different one by default.
- **InnoDB** — Used for transaction processing applications, and sports a number of features including ACID transaction support and foreign keys. **InnoDB** is included by default in all MySQL 5.1 binary distributions. In source distributions, you can enable or disable either engine by configuring MySQL as you like.
- **Memory** — Stores all data in RAM for extremely fast access in environments that require quick

lookups of reference and other like data. This engine was formerly known as the [HEAP](#) engine.

- [Merge](#) — Allows a MySQL DBA or developer to logically group a series of identical [MyISAM](#) tables and reference them as one object. Good for VLDB environments such as data warehousing.
- [Archive](#) — Provides the perfect solution for storing and retrieving large amounts of seldom-referenced historical, archived, or security audit information.
- [Federated](#) — Offers the ability to link separate MySQL servers to create one logical database from many physical servers. Very good for distributed or data mart environments.
- [NDB](#) — The Clustered database engine that is particularly suited for applications with high performance lookup needs that also require the highest possible degree of uptime and availability.
- [CSV](#) — The CSV storage engine stores data in text files using comma-separated values format. You can use the CSV engine to easily exchange data between other software and applications that can import and export in CSV format.
- [Blackhole](#) — The Blackhole storage engine accepts but does not store data and retrievals always return an empty set. The functionality can be used in distributed database design where data is automatically replicated, but not stored locally.
- [Example](#) — The Example storage engine is “stub” engine that does nothing. You can create tables with this engine, but no data can be stored in them or retrieved from them. The purpose of this engine is to serve as an example in the MySQL source code that illustrates how to begin writing new storage engines. As such, it is primarily of interest to developers.

This chapter describes each of the MySQL storage engines except for [NDB Cluster](#), which is covered in [Chapter 15, MySQL Cluster](#).

It is important to remember that you are not restricted to using the same storage engine for an entire server or schema: you can use a different storage engine for each table in your schema.

14.2.1. Choosing a Storage Engine

The various storage engines provided with MySQL are designed with different use-cases in mind. To use the pluggable storage architecture effectively, it is good to have an idea of the benefits and drawbacks of the various storage engines. The following table provides an overview of some storage engines provided with MySQL:

Feature	MyISAM	Memory	InnoDB	Archive	NDB
Storage limits	256TB	Yes	64TB	No	384EB ^[4]
Transactions	No	No	Yes	No	Yes
Locking granularity	Table	Table	Row	Row	Row
MVCC (snapshot read)	No	No	Yes	Yes	No
Geospatial support	Yes	No	Yes ^[1]	Yes ^[1]	Yes ^[1]
B-tree indexes	Yes	Yes	Yes	No	Yes
Hash indexes	No	Yes	No	No	Yes
Full-text search indexes	Yes	No	No	No	No
Clustered indexes	No	No	Yes	No	No
Data caches	No	N/A	Yes	No	Yes

Index caches	Yes	N/A	Yes	No	Yes
Compressed data	Yes	No	No	Yes	No
Encrypted data ^[2]	Yes	Yes	Yes	Yes	Yes
Cluster database support	No	No	No	No	Yes
Replication support ^[3]	Yes	Yes	Yes	Yes	Yes
Foreign key support	No	No	Yes	No	No
Backup / point-in-time recovery ^[3]	Yes	Yes	Yes	Yes	Yes
Query cache support	Yes	Yes	Yes	Yes	Yes
Update statistics for data dictionary	Yes	Yes	Yes	Yes	Yes

- [1] Storage engine supports spatial data types but no indexing of such data
- [2] Implemented in the server (via encryption functions), rather than in the storage engine
- [3] Implemented in the server, rather than in the storage engine
- [4] EB = exabyte (1024 * 1024 terabyte)

14.2.2. Comparing Transaction and Non-Transaction Engines

Transaction-safe tables (TSTs) have several advantages over non-transaction-safe tables (NTSTs):

- They are safer. Even if MySQL crashes or you get hardware problems, you can get your data back, either by automatic recovery or from a backup plus the transaction log.
- You can combine many statements and accept them all at the same time with the `COMMIT` statement (if autocommit is disabled).
- You can execute `ROLLBACK` to ignore your changes (if autocommit is disabled).
- If an update fails, all of your changes are reverted. (With non-transaction-safe tables, all changes that have taken place are permanent.)
- Transaction-safe storage engines can provide better concurrency for tables that get many updates concurrently with reads.

You can combine transaction-safe and non-transaction-safe tables in the same statements to get the best of both worlds. However, although MySQL supports several transaction-safe storage engines, for best results, you should not mix different storage engines within a transaction with autocommit disabled. For example, if you do this, changes to non-transaction-safe tables still are committed immediately and cannot be rolled back. For information about this and other problems that can occur in transactions that use mixed storage engines, see [Section 13.4.1, “START TRANSACTION, COMMIT, and ROLLBACK Syntax”](#).

Non-transaction-safe tables have several advantages of their own, all of which occur because there is no transaction overhead:

- Much faster
- Lower disk space requirements
- Less memory required to perform updates

14.2.3. Other Storage Engines

Other storage engines may be available from third parties and community members that have used the Custom Storage Engine interface.

You can find more information on the list of third party storage engines on the [MySQL Forge Storage Engines](http://forge.mysql.com/projects/search.php?t=tag&k=storage%20engine) [http://forge.mysql.com/projects/search.php?t=tag&k=storage%20engine] page.

Note. Third party engines are not supported by MySQL. For further information, documentation, installation guides, bug reporting or for any any help or assistance with these engines, please contact the developer of the engine directly.

Third party engines that are known to be available include the following; please see the MySQL Forge links provided for more information:

- **PrimeBase XT (PBXT)** [http://forge.mysql.com/projects/view.php?id=43] — PBXT has been designed for modern, web-based, high concurrency environments.
- **RitmarkFS** [http://forge.mysql.com/projects/view.php?id=82] — RitmarkFS allows you to access and manipulate the filesystem using SQL queries. RitmarkFS also supports filesystem replication and directory change tracking.
- **Distributed Data Engine** [http://forge.mysql.com/projects/view.php?id=91] — The Distributed Data Engine is an Open Source project that is dedicated to provide a Storage Engine for distributed data according to workload statistics.
- **mdbtools** [http://forge.mysql.com/projects/view.php?id=98] — A pluggable storage engine that allows read-only access to MicroSoft Access `.mdb` database files.
- **solidDB for MySQL** [http://forge.mysql.com/projects/view.php?id=139] — solidDB Storage Engine for MySQL is an open source, transactional storage engine for MySQL Server. It is designed for mission-critical implementations that require a robust, transactional database. solidDB Storage Engine for MySQL is a multi-threaded storage engine that supports full ACID compliance with all expected transaction isolation levels, row-level locking, and Multi-Version Concurrency Control (MVCC) with non-blocking reads and writes.

For more information on developing a customer storage engine that can be used with the Pluggable Storage Engine Architecture, see [Writing a Custom Storage Engine](http://dev.mysql.com/doc/internals/en/custom-engine.html) [http://dev.mysql.com/doc/internals/en/custom-engine.html], of the MySQL Internals manual.

14.3. Setting the Storage Engine

When you create a new table, you can specify which storage engine to use by adding an `ENGINE` table option to the `CREATE TABLE` statement:

```
CREATE TABLE t (i INT) ENGINE = INNODB;
```

If you omit the `ENGINE` or `TYPE` option, the default storage engine is used. Normally, this is `MyISAM`,

but you can change it by using the `--default-storage-engine` or `--default-table-type` server startup option, or by setting the `default-storage-engine` or `default-table-type` option in the `my.cnf` configuration file.

You can set the default storage engine to be used during the current session by setting the `storage_engine` or `table_type` variable:

```
SET storage_engine=MYISAM;
SET table_type=INNODB;
```

When MySQL is installed on Windows using the MySQL Configuration Wizard, the `InnoDB` storage engine can be selected as the default instead of `MyISAM`. See [Section 2.3.4.6, “The Database Usage Dialog”](#).

To convert a table from one storage engine to another, use an `ALTER TABLE` statement that indicates the new engine:

```
ALTER TABLE t ENGINE = MYISAM;
```

See [Section 13.1.7, “CREATE TABLE Syntax”](#), and [Section 13.1.2, “ALTER TABLE Syntax”](#).

If you try to use a storage engine that is not compiled in or that is compiled in but deactivated, MySQL instead creates a table using the default storage engine, usually `MyISAM`. This behavior is convenient when you want to copy tables between MySQL servers that support different storage engines. (For example, in a replication setup, perhaps your master server supports transactional storage engines for increased safety, but the slave servers use only non-transactional storage engines for greater speed.)

This automatic substitution of the default storage engine for unavailable engines can be confusing for new MySQL users. A warning is generated whenever a storage engine is automatically changed.

For new tables, MySQL always creates an `.frm` file to hold the table and column definitions. The table's index and data may be stored in one or more other files, depending on the storage engine. The server creates the `.frm` file above the storage engine level. Individual storage engines create any additional files required for the tables that they manage. If a table name contains special characters, the names for the table files contain encoded versions of those characters as described in [Section 9.2.3, “Mapping of Identifiers to Filenames”](#).

A database may contain tables of different types. That is, tables need not all be created with the same storage engine.

14.4. The `MyISAM` Storage Engine

`MyISAM` is the default storage engine. It is based on the older `ISAM` code but has many useful extensions. (Note that MySQL 5.1 does *not* support `ISAM`.)

Each `MyISAM` table is stored on disk in three files. The files have names that begin with the table name and have an extension to indicate the file type. An `.frm` file stores the table format. The data file has an `.MYD` (`MYData`) extension. The index file has an `.MYI` (`MYIndex`) extension.

To specify explicitly that you want a `MyISAM` table, indicate that with an `ENGINE` table option:

```
CREATE TABLE t (i INT) ENGINE = MYISAM;
```

Normally, it is unnecessary to use `ENGINE` to specify the `MyISAM` storage engine. `MyISAM` is the default engine unless the default has been changed. To ensure that `MyISAM` is used in situations where the default might have been changed, include the `ENGINE` option explicitly.

You can check or repair `MyISAM` tables with the `mysqlcheck` client or `myisamchk` utility. You can

also compress `MyISAM` tables with `myisampack` to take up much less space. See [Section 8.10](#), “`mysqlcheck` — A Table Maintenance and Repair Program”, [Section 5.10.4.1](#), “Using `myisamchk` for Crash Recovery”, and [Section 8.5](#), “`myisampack` — Generate Compressed, Read-Only `MyISAM` Tables”.

`MyISAM` tables have the following characteristics:

- All data values are stored with the low byte first. This makes the data machine and operating system independent. The only requirements for binary portability are that the machine uses two's-complement signed integers and IEEE floating-point format. These requirements are widely used among mainstream machines. Binary compatibility might not be applicable to embedded systems, which sometimes have peculiar processors.

There is no significant speed penalty for storing data low byte first; the bytes in a table row normally are unaligned and it takes little more processing to read an unaligned byte in order than in reverse order. Also, the code in the server that fetches column values is not time critical compared to other code.

- All numeric key values are stored with the high byte first to allow better index compression.
- Large files (up to 63-bit file length) are supported on filesystems and operating systems that support large files.
- There is a limit of 2^{32} (~4.295E+09) rows in a `MyISAM` table. You can increase this limitation if you build MySQL with the `--with-big-tables` option then the row limitation is increased to $(2^{32})^2$ (1.844E+19) rows. See [Section 2.9.2](#), “Typical configure Options”. Beginning with MySQL 5.0.4 all standard binaries are built with this option.
- The maximum number of indexes per `MyISAM` table is 64. This can be changed by recompiling. Beginning with MySQL 5.1.4, you can configure the build by invoking `configure` with the `--with-max-indexes=N` option, where `N` is the maximum number of indexes to permit per `MyISAM` table. `N` must be less than or equal to 128. Before MySQL 5.1.4, you must change the source.

The maximum number of columns per index is 16.

- The maximum key length is 1000 bytes. This can also be changed by changing the source and recompiling. For the case of a key longer than 250 bytes, a larger key block size than the default of 1024 bytes is used.
- When rows are inserted in sorted order (as when you are using an `AUTO_INCREMENT` column), the index tree is split so that the high node only contains one key. This improves space utilization in the index tree.
- Internal handling of one `AUTO_INCREMENT` column per table is supported. `MyISAM` automatically updates this column for `INSERT` and `UPDATE` operations. This makes `AUTO_INCREMENT` columns faster (at least 10%). Values at the top of the sequence are not reused after being deleted. (When an `AUTO_INCREMENT` column is defined as the last column of a multiple-column index, re-use of values deleted from the top of a sequence does occur.) The `AUTO_INCREMENT` value can be reset with `ALTER TABLE` or `myisamchk`.
- Dynamic-sized rows are much less fragmented when mixing deletes with updates and inserts. This is done by automatically combining adjacent deleted blocks and by extending blocks if the next block is deleted.
- If a table has no free blocks in the middle of the data file, you can `INSERT` new rows into it at the same time that other threads are reading from the table. (These are known as concurrent inserts.) A free block can occur as a result of deleting rows or an update of a dynamic length row with more data than its current contents. When all free blocks are used up (filled in), future inserts become concurrent again. See [Section 7.3.3](#), “Concurrent Inserts”.

- You can put the data file and index file on different directories to get more speed with the `DATA DIRECTORY` and `INDEX DIRECTORY` table options to `CREATE TABLE`. See [Section 13.1.7, “CREATE TABLE Syntax”](#).
- `BLOB` and `TEXT` columns can be indexed.
- `NULL` values are allowed in indexed columns. This takes 0–1 bytes per key.
- Each character column can have a different character set. See [Chapter 10, Character Set Support](#).
- There is a flag in the `MyISAM` index file that indicates whether the table was closed correctly. If `mysqld` is started with the `--myisam-recover` option, `MyISAM` tables are automatically checked when opened, and are repaired if the table wasn't closed properly.
- `myisamchk` marks tables as checked if you run it with the `--update-state` option. `myisamchk --fast` checks only those tables that don't have this mark.
- `myisamchk --analyze` stores statistics for portions of keys, as well as for entire keys.
- `myisampack` can pack `BLOB` and `VARCHAR` columns.

`MyISAM` also supports the following features:

- Support for a true `VARCHAR` type; a `VARCHAR` column starts with a length stored in one or two bytes.
- Tables with `VARCHAR` columns may have fixed or dynamic row length.
- The sum of the lengths of the `VARCHAR` and `CHAR` columns in a table may be up to 64KB.
- A hashed computed index can be used for `UNIQUE`. This allows you to have `UNIQUE` on any combination of columns in a table. (However, you cannot search on a `UNIQUE` computed index.)

Additional resources

- A forum dedicated to the `MyISAM` storage engine is available at <http://forums.mysql.com/list.php?21>.

14.4.1. `MyISAM` Startup Options

The following options to `mysqld` can be used to change the behavior of `MyISAM` tables. For additional information, see [Section 5.2.2, “Command Options”](#).

- `--myisam-recover=mode`

Set the mode for automatic recovery of crashed `MyISAM` tables.

- `--delay-key-write=ALL`

Don't flush key buffers between writes for any `MyISAM` table.

Note: If you do this, you should not access `MyISAM` tables from another program (such as from another MySQL server or with `myisamchk`) when the tables are in use. Doing so risks index corrup-

tion. Using `--external-locking` does not eliminate this risk.

The following system variables affect the behavior of `MyISAM` tables. For additional information, see [Section 5.2.3, “System Variables”](#).

- `bulk_insert_buffer_size`

The size of the tree cache used in bulk insert optimization. **Note:** This is a limit *per thread*!

- `myisam_max_sort_file_size`

The maximum size of the temporary file that MySQL is allowed to use while re-creating a `MyISAM` index (during `REPAIR TABLE`, `ALTER TABLE`, or `LOAD DATA INFILE`). If the file size would be larger than this value, the index is created using the key cache instead, which is slower. The value is given in bytes.

- `myisam_sort_buffer_size`

Set the size of the buffer used when recovering tables.

Automatic recovery is activated if you start `mysqld` with the `--myisam-recover` option. In this case, when the server opens a `MyISAM` table, it checks whether the table is marked as crashed or whether the open count variable for the table is not 0 and you are running the server with external locking disabled. If either of these conditions is true, the following happens:

- The server checks the table for errors.
- If the server finds an error, it tries to do a fast table repair (with sorting and without re-creating the data file).
- If the repair fails because of an error in the data file (for example, a duplicate-key error), the server tries again, this time re-creating the data file.
- If the repair still fails, the server tries once more with the old repair option method (write row by row without sorting). This method should be able to repair any type of error and has low disk space requirements.

If the recovery wouldn't be able to recover all rows from previously completed statements and you didn't specify `FORCE` in the value of the `--myisam-recover` option, automatic repair aborts with an error message in the error log:

```
Error: Couldn't repair table: test.g00pages
```

If you specify `FORCE`, a warning like this is written instead:

```
Warning: Found 344 of 354 rows when repairing ./test/g00pages
```

Note that if the automatic recovery value includes `BACKUP`, the recovery process creates files with names of the form `tbl_name-datetime.BAK`. You should have a `cron` script that automatically moves these files from the database directories to backup media.

14.4.2. Space Needed for Keys

`MyISAM` tables use B-tree indexes. You can roughly calculate the size for the index file as $(key_length+4)/0.67$, summed over all keys. This is for the worst case when all keys are inserted in sorted order and the table doesn't have any compressed keys.

String indexes are space compressed. If the first index part is a string, it is also prefix compressed. Space compression makes the index file smaller than the worst-case figure if a string column has a lot of trailing space or is a `VARCHAR` column that is not always used to the full length. Prefix compression is used on keys that start with a string. Prefix compression helps if there are many strings with an identical prefix.

In `MyISAM` tables, you can also prefix compress numbers by specifying the `PACK_KEYS=1` table option when you create the table. Numbers are stored with the high byte first, so this helps when you have many integer keys that have an identical prefix.

14.4.3. `MyISAM` Table Storage Formats

`MyISAM` supports three different storage formats. Two of them, fixed and dynamic format, are chosen automatically depending on the type of columns you are using. The third, compressed format, can be created only with the `myisampack` utility.

When you use `CREATE TABLE` or `ALTER TABLE` for a table that has no `BLOB` or `TEXT` columns, you can force the table format to `FIXED` or `DYNAMIC` with the `ROW_FORMAT` table option.

You can decompress tables by specifying `ROW_FORMAT=DEFAULT` with `ALTER TABLE`.

See [Section 13.1.7, “CREATE TABLE Syntax”](#), for information about `ROW_FORMAT`.

14.4.3.1. Static (Fixed-Length) Table Characteristics

Static format is the default for `MyISAM` tables. It is used when the table contains no variable-length columns (`VARCHAR`, `VARBINARY`, `BLOB`, or `TEXT`). Each row is stored using a fixed number of bytes.

Of the three `MyISAM` storage formats, static format is the simplest and most secure (least subject to corruption). It is also the fastest of the on-disk formats due to the ease with which rows in the data file can be found on disk: To look up a row based on a row number in the index, multiply the row number by the row length to calculate the row position. Also, when scanning a table, it is very easy to read a constant number of rows with each disk read operation.

The security is evidenced if your computer crashes while the MySQL server is writing to a fixed-format `MyISAM` file. In this case, `myisamchk` can easily determine where each row starts and ends, so it can usually reclaim all rows except the partially written one. Note that `MyISAM` table indexes can always be reconstructed based on the data rows.

Static-format tables have these characteristics:

- `CHAR` columns are space-padded to the column width. `BINARY` columns are padded with `0x00` bytes to the column width.
- Very quick.
- Easy to cache.
- Easy to reconstruct after a crash, because rows are located in fixed positions.
- Reorganization is unnecessary unless you delete a huge number of rows and want to return free disk space to the operating system. To do this, use `OPTIMIZE TABLE` or `myisamchk -r`.

- Usually require more disk space than dynamic-format tables.

14.4.3.2. Dynamic Table Characteristics

Dynamic storage format is used if a `MyISAM` table contains any variable-length columns (`VARCHAR`, `VARBINARY`, `BLOB`, or `TEXT`), or if the table was created with the `ROW_FORMAT=DYNAMIC` table option.

Dynamic format is a little more complex than static format because each row has a header that indicates how long it is. A row can become fragmented (stored in non-contiguous pieces) when it is made longer as a result of an update.

You can use `OPTIMIZE TABLE` or `myisamchk -r` to defragment a table. If you have fixed-length columns that you access or change frequently in a table that also contains some variable-length columns, it might be a good idea to move the variable-length columns to other tables just to avoid fragmentation.

Dynamic-format tables have these characteristics:

- All string columns are dynamic except those with a length less than four.
- Each row is preceded by a bitmap that indicates which columns contain the empty string (for string columns) or zero (for numeric columns). Note that this does not include columns that contain `NULL` values. If a string column has a length of zero after trailing space removal, or a numeric column has a value of zero, it is marked in the bitmap and not saved to disk. Non-empty strings are saved as a length byte plus the string contents.
- Much less disk space usually is required than for fixed-length tables.
- Each row uses only as much space as is required. However, if a row becomes larger, it is split into as many pieces as are required, resulting in row fragmentation. For example, if you update a row with information that extends the row length, the row becomes fragmented. In this case, you may have to run `OPTIMIZE TABLE` or `myisamchk -r` from time to time to improve performance. Use `myisamchk -ei` to obtain table statistics.
- More difficult than static-format tables to reconstruct after a crash, because rows may be fragmented into many pieces and links (fragments) may be missing.
- The expected row length for dynamic-sized rows is calculated using the following expression:

```

3
+ (number of columns + 7) / 8
+ (number of char columns)
+ (packed size of numeric columns)
+ (length of strings)
+ (number of NULL columns + 7) / 8

```

There is a penalty of 6 bytes for each link. A dynamic row is linked whenever an update causes an enlargement of the row. Each new link is at least 20 bytes, so the next enlargement probably goes in the same link. If not, another link is created. You can find the number of links using `myisamchk -ed`. All links may be removed with `OPTIMIZE TABLE` or `myisamchk -r`.

14.4.3.3. Compressed Table Characteristics

Compressed storage format is a read-only format that is generated with the `myisampack` tool. Compressed tables can be uncompressed with `myisamchk`.

Compressed tables have the following characteristics:

- Compressed tables take very little disk space. This minimizes disk usage, which is helpful when using slow disks (such as CD-ROMs).
- Each row is compressed separately, so there is very little access overhead. The header for a row takes up one to three bytes depending on the biggest row in the table. Each column is compressed differently. There is usually a different Huffman tree for each column. Some of the compression types are:
 - Suffix space compression.
 - Prefix space compression.
 - Numbers with a value of zero are stored using one bit.
 - If values in an integer column have a small range, the column is stored using the smallest possible type. For example, a `BIGINT` column (eight bytes) can be stored as a `TINYINT` column (one byte) if all its values are in the range from `-128` to `127`.
 - If a column has only a small set of possible values, the data type is converted to `ENUM`.
 - A column may use any combination of the preceding compression types.
- Can be used for fixed-length or dynamic-length rows.

Note. While a compressed table is read-only, and you cannot therefore update or add rows in the table, DDL (Data Definition Language) operations are still valid. For example, you may still use `DROP` to drop the table, and `TRUNCATE` to empty the table.

14.4.4. `MyISAM` Table Problems

The file format that MySQL uses to store data has been extensively tested, but there are always circumstances that may cause database tables to become corrupted. The following discussion describes how this can happen and how to handle it.

14.4.4.1. Corrupted `MyISAM` Tables

Even though the `MyISAM` table format is very reliable (all changes to a table made by an SQL statement are written before the statement returns), you can still get corrupted tables if any of the following events occur:

- The `mysqld` process is killed in the middle of a write.
- An unexpected computer shutdown occurs (for example, the computer is turned off).
- Hardware failures.
- You are using an external program (such as `myisamchk`) to modify a table that is being modified by the server at the same time.
- A software bug in the MySQL or `MyISAM` code.

Typical symptoms of a corrupt table are:

- You get the following error while selecting data from the table:

```
Incorrect key file for table: '...'. Try to repair it
```

- Queries don't find rows in the table or return incomplete results.

You can check the health of a `MyISAM` table using the `CHECK TABLE` statement, and repair a corrupted `MyISAM` table with `REPAIR TABLE`. When `mysqld` is not running, you can also check or repair a table with the `myisamchk` command. See [Section 13.5.2.3, “CHECK TABLE Syntax”](#), [Section 13.5.2.6, “REPAIR TABLE Syntax”](#), and [Section 8.3, “myisamchk — MyISAM Table-Maintenance Utility”](#).

If your tables become corrupted frequently, you should try to determine why this is happening. The most important thing to know is whether the table became corrupted as a result of a server crash. You can verify this easily by looking for a recent `restarted mysqld` message in the error log. If there is such a message, it is likely that table corruption is a result of the server dying. Otherwise, corruption may have occurred during normal operation. This is a bug. You should try to create a reproducible test case that demonstrates the problem. See [Section A.4.2, “What to Do If MySQL Keeps Crashing”](#), and [Section E.1.6, “Making a Test Case If You Experience Table Corruption”](#).

14.4.4.2. Problems from Tables Not Being Closed Properly

Each `MyISAM` index file (`.MYI` file) has a counter in the header that can be used to check whether a table has been closed properly. If you get the following warning from `CHECK TABLE` or `myisamchk`, it means that this counter has gone out of sync:

```
clients are using or haven't closed the table properly
```

This warning doesn't necessarily mean that the table is corrupted, but you should at least check the table.

The counter works as follows:

- The first time a table is updated in MySQL, a counter in the header of the index files is incremented.
- The counter is not changed during further updates.
- When the last instance of a table is closed (because a `FLUSH TABLES` operation was performed or because there is no room in the table cache), the counter is decremented if the table has been updated at any point.
- When you repair the table or check the table and it is found to be okay, the counter is reset to zero.
- To avoid problems with interaction with other processes that might check the table, the counter is not decremented on close if it was zero.

In other words, the counter can become incorrect only under these conditions:

- A `MyISAM` table is copied without first issuing `LOCK TABLES` and `FLUSH TABLES`.
- MySQL has crashed between an update and the final close. (Note that the table may still be okay, because MySQL always issues writes for everything between each statement.)
- A table was modified by `myisamchk --recover` or `myisamchk --update-state` at the same time that it was in use by `mysqld`.

- Multiple `mysqld` servers are using the table and one server performed a `REPAIR TABLE` or `CHECK TABLE` on the table while it was in use by another server. In this setup, it is safe to use `CHECK TABLE`, although you might get the warning from other servers. However, `REPAIR TABLE` should be avoided because when one server replaces the data file with a new one, this is not known to the other servers.

In general, it is a bad idea to share a data directory among multiple servers. See [Section 5.13, “Running Multiple MySQL Servers on the Same Machine”](#), for additional discussion.

14.5. The InnoDB Storage Engine

14.5.1. InnoDB Overview

`InnoDB` provides MySQL with a transaction-safe (ACID compliant) storage engine that has commit, rollback, and crash recovery capabilities. `InnoDB` does locking on the row level and also provides an Oracle-style consistent non-locking read in `SELECT` statements. These features increase multi-user concurrency and performance. There is no need for lock escalation in `InnoDB` because row-level locks fit in very little space. `InnoDB` also supports `FOREIGN KEY` constraints. You can freely mix `InnoDB` tables with tables from other MySQL storage engines, even within the same statement.

`InnoDB` has been designed for maximum performance when processing large data volumes. Its CPU efficiency is probably not matched by any other disk-based relational database engine.

Fully integrated with MySQL Server, the `InnoDB` storage engine maintains its own buffer pool for caching data and indexes in main memory. `InnoDB` stores its tables and indexes in a tablespace, which may consist of several files (or raw disk partitions). This is different from, for example, `MyISAM` tables where each table is stored using separate files. `InnoDB` tables can be of any size even on operating systems where file size is limited to 2GB.

`InnoDB` is included in binary distributions by default. The Windows Essentials installer makes `InnoDB` the MySQL default storage engine on Windows.

`InnoDB` is used in production at numerous large database sites requiring high performance. The famous Internet news site Slashdot.org runs on `InnoDB`. Myrix, Inc. stores over 1TB of data in `InnoDB`, and another site handles an average load of 800 inserts/updates per second in `InnoDB`.

`InnoDB` is published under the same GNU GPL License Version 2 (of June 1991) as MySQL. For more information on MySQL licensing, see <http://www.mysql.com/company/legal/licensing/>.

Additional resources

- A forum dedicated to the `InnoDB` storage engine is available at <http://forums.mysql.com/list.php?22>.

14.5.2. InnoDB Contact Information

Contact information for Innobase Oy, producer of the `InnoDB` engine:

```

```
00101 Helsinki
Finland
```

14.5.3. InnoDB Configuration

The `InnoDB` storage engine is enabled by default. If you don't want to use `InnoDB` tables, you can add the `skip-innodb` option to your MySQL option file.

Note: `InnoDB` provides MySQL with a transaction-safe (`ACID` compliant) storage engine that has commit, rollback, and crash recovery capabilities. **However, it cannot do so** if the underlying operating system or hardware does not work as advertised. Many operating systems or disk subsystems may delay or reorder write operations to improve performance. On some operating systems, the very system call that should wait until all unwritten data for a file has been flushed — `fsync()` — might actually return before the data has been flushed to stable storage. Because of this, an operating system crash or a power outage may destroy recently committed data, or in the worst case, even corrupt the database because of write operations having been reordered. If data integrity is important to you, you should perform some “pull-the-plug” tests before using anything in production. On Mac OS X 10.3 and up, `InnoDB` uses a special `fcntl()` file flush method. Under Linux, it is advisable to **disable the write-back cache**.

On ATAPI hard disks, a command such `hdparm -W0 /dev/hda` may work to disable the write-back cache. **Beware that some drives or disk controllers may be unable to disable the write-back cache.**

Two important disk-based resources managed by the `InnoDB` storage engine are its tablespace data files and its log files.

Note: If you specify no `InnoDB` configuration options, MySQL creates an auto-extending 10MB data file named `ibdata1` and two 5MB log files named `ib_logfile0` and `ib_logfile1` in the MySQL data directory. To get good performance, you should explicitly provide `InnoDB` parameters as discussed in the following examples. Naturally, you should edit the settings to suit your hardware and requirements.

The examples shown here are representative. See [Section 14.5.4, “InnoDB Startup Options and System Variables”](#) for additional information about `InnoDB`-related configuration parameters.

To set up the `InnoDB` tablespace files, use the `innodb_data_file_path` option in the `[mysqld]` section of the `my.cnf` option file. On Windows, you can use `my.ini` instead. The value of `innodb_data_file_path` should be a list of one or more data file specifications. If you name more than one data file, separate them by semicolon (`;`) characters:

```
innodb_data_file_path=datafile_spec1[:datafile_spec2]...
```

For example, a setting that explicitly creates a tablespace having the same characteristics as the default is as follows:

```
[mysqld]
innodb_data_file_path=ibdata1:10M:autoextend
```

This setting configures a single 10MB data file named `ibdata1` that is auto-extending. No location for the file is given, so by default, `InnoDB` creates it in the MySQL data directory.

Sizes are specified using `M` or `G` suffix letters to indicate units of MB or GB.

A tablespace containing a fixed-size 50MB data file named `ibdata1` and a 50MB auto-extending file named `ibdata2` in the data directory can be configured like this:

```
[mysqld]
innodb_data_file_path=ibdata1:50M;ibdata2:50M:autoextend
```

The full syntax for a data file specification includes the filename, its size, and several optional attributes:

```
file_name:file_size[:autoextend[:max:max_file_size]]
```

The `autoextend` attribute and those following can be used only for the last data file in the `innodb_data_file_path` line.

If you specify the `autoextend` option for the last data file, `InnoDB` extends the data file if it runs out of free space in the tablespace. The increment is 8MB at a time by default. It can be modified by changing the `innodb_autoextend_increment` system variable.

If the disk becomes full, you might want to add another data file on another disk. Instructions for reconfiguring an existing tablespace are given in [Section 14.5.7, “Adding and Removing InnoDB Data and Log Files”](#).

`InnoDB` is not aware of the filesystem maximum file size, so be cautious on filesystems where the maximum file size is a small value such as 2GB. To specify a maximum size for an auto-extending data file, use the `max` attribute. The following configuration allows `ibdata1` to grow up to a limit of 500MB:

```
[mysqld]
innodb_data_file_path=ibdata1:10M:autoextend:max:500M
```

`InnoDB` creates tablespace files in the MySQL data directory by default. To specify a location explicitly, use the `innodb_data_home_dir` option. For example, to use two files named `ibdata1` and `ibdata2` but create them in the `/ibdata` directory, configure `InnoDB` like this:

```
[mysqld]
innodb_data_home_dir = /ibdata
innodb_data_file_path=ibdata1:50M;ibdata2:50M:autoextend
```

Note: `InnoDB` does not create directories, so make sure that the `/ibdata` directory exists before you start the server. This is also true of any log file directories that you configure. Use the Unix or DOS `mkdir` command to create any necessary directories.

`InnoDB` forms the directory path for each data file by textually concatenating the value of `innodb_data_home_dir` to the data file name, adding a pathname separator (slash or backslash) between values if necessary. If the `innodb_data_home_dir` option is not mentioned in `my.cnf` at all, the default value is the “dot” directory `./`, which means the MySQL data directory. (The MySQL server changes its current working directory to its data directory when it begins executing.)

If you specify `innodb_data_home_dir` as an empty string, you can specify absolute paths for the data files listed in the `innodb_data_file_path` value. The following example is equivalent to the preceding one:

```
[mysqld]
innodb_data_home_dir =
innodb_data_file_path=/ibdata/ibdata1:50M;/ibdata/ibdata2:50M:autoextend
```

A simple `my.cnf` example. Suppose that you have a computer with 128MB RAM and one hard disk. The following example shows possible configuration parameters in `my.cnf` or `my.ini` for `InnoDB`, including the `autoextend` attribute. The example suits most users, both on Unix and Windows, who do not want to distribute `InnoDB` data files and log files onto several disks. It creates an auto-extending data file `ibdata1` and two `InnoDB` log files `ib_logfile0` and `ib_logfile1` in the MySQL data directory. Also, the small archived `InnoDB` log file `ib_arch_log_0000000000` that `InnoDB` creates automatically ends up in the data directory.

```
[mysqld]
# You can write your other MySQL server options here
# ...
# Data files must be able to hold your data and indexes.
```

```
# Make sure that you have enough free disk space.
innodb_data_file_path = ibdata1:10M:autoextend
#
# Set buffer pool size to 50-80% of your computer's memory
innodb_buffer_pool_size=70M
innodb_additional_mem_pool_size=10M
#
# Set the log file size to about 25% of the buffer pool size
innodb_log_file_size=20M
innodb_log_buffer_size=8M
#
innodb_flush_log_at_trx_commit=1
```

Make sure that the MySQL server has the proper access rights to create files in the data directory. More generally, the server must have access rights in any directory where it needs to create data files or log files.

Note that data files must be less than 2GB in some filesystems. The combined size of the log files must be less than 4GB. The combined size of data files must be at least 10MB.

When you create an [InnoDB](#) tablespace for the first time, it is best that you start the MySQL server from the command prompt. [InnoDB](#) then prints the information about the database creation to the screen, so you can see what is happening. For example, on Windows, if `mysqld` is located in `C:\Program Files\MySQL\MySQL Server 5.1\bin`, you can start it like this:

```
C:\> "C:\Program Files\MySQL\MySQL Server 5.1\bin\mysqld" --console
```

If you do not send server output to the screen, check the server's error log to see what [InnoDB](#) prints during the startup process.

See [Section 14.5.5, "Creating the InnoDB Tablespace"](#), for an example of what the information displayed by [InnoDB](#) should look like.

You can place [InnoDB](#) options in the `[mysqld]` group of any option file that your server reads when it starts. The locations for option files are described in [Section 4.3.2, "Using Option Files"](#).

If you installed MySQL on Windows using the installation and configuration wizards, the option file will be the `my.ini` file located in your MySQL installation directory. See [Section 2.3.4.14, "The Location of the my.ini File"](#).

If your PC uses a boot loader where the `C:` drive is not the boot drive, your only option is to use the `my.ini` file in your Windows directory (typically `C:\WINDOWS` or `C:\WINNT`). You can use the `SET` command at the command prompt in a console window to print the value of `WINDIR`:

```
C:\> SET WINDIR
windir=C:\WINDOWS
```

If you want to make sure that `mysqld` reads options only from a specific file, you can use the `--defaults-file` option as the first option on the command line when starting the server:

```
mysqld --defaults-file=your_path_to_my_cnf
```

An advanced `my.cnf` example. Suppose that you have a Linux computer with 2GB RAM and three 60GB hard disks at directory paths `/`, `/dr2` and `/dr3`. The following example shows possible configuration parameters in `my.cnf` for [InnoDB](#).

```
[mysqld]
# You can write your other MySQL server options here
# ...
innodb_data_home_dir =
#
# Data files must be able to hold your data and indexes
```

```

innodb_data_file_path = /db/ibdata1:2000M:/dr2/db/ibdata2:2000M:autoextend
#
# Set buffer pool size to 50-80% of your computer's memory,
# but make sure on Linux x86 total memory usage is < 2GB
innodb_buffer_pool_size=1G
innodb_additional_mem_pool_size=20M
innodb_log_group_home_dir = /dr3/iblogs
#
innodb_log_files_in_group = 2
#
# Set the log file size to about 25% of the buffer pool size
innodb_log_file_size=250M
innodb_log_buffer_size=8M
#
innodb_flush_log_at_trx_commit=1
innodb_lock_wait_timeout=50
#
# Uncomment the next lines if you want to use them
#innodb_thread_concurrency=5

```

In some cases, database performance improves if all data is not placed on the same physical disk. Putting log files on a different disk from data is very often beneficial for performance. The example illustrates how to do this. It places the two data files on different disks and places the log files on the third disk. InnoDB fills the tablespace beginning with the first data file. You can also use raw disk partitions (raw devices) as InnoDB data files, which may speed up I/O. See [Section 14.5.3.2, “Using Raw Devices for the Shared Tablespace”](#).

Warning: On 32-bit GNU/Linux x86, you must be careful not to set memory usage too high. `glibc` may allow the process heap to grow over thread stacks, which crashes your server. It is a risk if the value of the following expression is close to or exceeds 2GB:

```

innodb_buffer_pool_size
+ key_buffer_size
+ max_connections*(sort_buffer_size+read_buffer_size+binlog_cache_size)
+ max_connections*2MB

```

Each thread uses a stack (often 2MB, but only 256KB in MySQL AB binaries) and in the worst case also uses `sort_buffer_size + read_buffer_size` additional memory.

By compiling MySQL yourself, you can use up to 64GB of physical memory in 32-bit Windows. See the description for `innodb_buffer_pool_awesome_mem_mb` in [Section 14.5.4, “InnoDB Startup Options and System Variables”](#).

How to tune other `mysqld` server parameters? The following values are typical and suit most users:

```

[mysqld]
skip-external-locking
max_connections=200
read_buffer_size=1M
sort_buffer_size=1M
#
# Set key_buffer to 5 - 50% of your RAM depending on how much
# you use MyISAM tables, but keep key_buffer_size + InnoDB
# buffer pool size < 80% of your RAM
key_buffer_size=value

```

14.5.3.1. Using Per-Table Tablespaces

You can store each InnoDB table and its indexes in its own file. This feature is called “multiple tablespaces” because in effect each table has its own tablespace.

Using multiple tablespaces can be beneficial to users who want to move specific tables to separate physical disks or who wish to restore backups of single tables quickly without interrupting the use of the remaining InnoDB tables.

You can enable multiple tablespaces by adding this line to the `[mysqld]` section of `my.cnf`:

```
[mysqld]
innodb_file_per_table
```

After restarting the server, **InnoDB** stores each newly created table into its own file `tbl_name.ibd` in the database directory where the table belongs. This is similar to what the **MyISAM** storage engine does, but **MyISAM** divides the table into a data file `tbl_name.MYD` and the index file `tbl_name.MYI`. For **InnoDB**, the data and the indexes are stored together in the `.ibd` file. The `tbl_name.frm` file is still created as usual.

If you remove the `innodb_file_per_table` line from `my.cnf` and restart the server, **InnoDB** creates tables inside the shared tablespace files again.

`innodb_file_per_table` affects only table creation, not access to existing tables. If you start the server with this option, new tables are created using `.ibd` files, but you can still access tables that exist in the shared tablespace. If you remove the option and restart the server, new tables are created in the shared tablespace, but you can still access any tables that were created using multiple tablespaces.

Note: **InnoDB** always needs the shared tablespace because it puts its internal data dictionary and undo logs there. The `.ibd` files are not sufficient for **InnoDB** to operate.

Note: You cannot freely move `.ibd` files between database directories as you can with **MyISAM** table files. This is because the table definition that is stored in the **InnoDB** shared tablespace includes the database name, and because **InnoDB** must preserve the consistency of transaction IDs and log sequence numbers.

To move an `.ibd` file and the associated table from one database to another, use a `RENAME TABLE` statement:

```
RENAME TABLE db1.tbl_name TO db2.tbl_name;
```

If you have a “clean” backup of an `.ibd` file, you can restore it to the MySQL installation from which it originated as follows:

1. Issue this `ALTER TABLE` statement:

```
ALTER TABLE tbl_name DISCARD TABLESPACE;
```

Caution: This statement deletes the current `.ibd` file.

2. Put the backup `.ibd` file back in the proper database directory.
3. Issue this `ALTER TABLE` statement:

```
ALTER TABLE tbl_name IMPORT TABLESPACE;
```

In this context, a “clean” `.ibd` file backup means:

- There are no uncommitted modifications by transactions in the `.ibd` file.
- There are no unmerged insert buffer entries in the `.ibd` file.
- Purge has removed all delete-marked index records from the `.ibd` file.

- `mysqld` has flushed all modified pages of the `.ibd` file from the buffer pool to the file.

You can make a clean backup `.ibd` file using the following method:

1. Stop all activity from the `mysqld` server and commit all transactions.
2. Wait until `SHOW ENGINE INNODB STATUS` shows that there are no active transactions in the database, and the main thread status of `InnoDB` is `Waiting for server activity`. Then you can make a copy of the `.ibd` file.

Another method for making a clean copy of an `.ibd` file is to use the commercial `InnoDB Hot Backup` tool:

1. Use `InnoDB Hot Backup` to back up the `InnoDB` installation.
2. Start a second `mysqld` server on the backup and let it clean up the `.ibd` files in the backup.

14.5.3.2. Using Raw Devices for the Shared Tablespace

You can use raw disk partitions as data files in the shared tablespace. By using a raw disk, you can perform non-buffered I/O on Windows and on some Unix systems without filesystem overhead, which may improve performance.

When you create a new data file, you must put the keyword `newraw` immediately after the data file size in `innodb_data_file_path`. The partition must be at least as large as the size that you specify. Note that 1MB in `InnoDB` is 1024×1024 bytes, whereas 1MB in disk specifications usually means 1,000,000 bytes.

```
[mysqld]
innodb_data_home_dir=
innodb_data_file_path=/dev/hdd1:3Gnewraw;/dev/hdd2:2Gnewraw
```

The next time you start the server, `InnoDB` notices the `newraw` keyword and initializes the new partition. However, do not create or change any `InnoDB` tables yet. Otherwise, when you next restart the server, `InnoDB` reinitializes the partition and your changes are lost. (As a safety measure `InnoDB` prevents users from modifying data when any partition with `newraw` is specified.)

After `InnoDB` has initialized the new partition, stop the server, change `newraw` in the data file specification to `raw`:

```
[mysqld]
innodb_data_home_dir=
innodb_data_file_path=/dev/hdd1:5Graw;/dev/hdd2:2Graw
```

Then restart the server and `InnoDB` allows changes to be made.

On Windows, you can allocate a disk partition as a data file like this:

```
[mysqld]
innodb_data_home_dir=
innodb_data_file_path=//./D: :10Gnewraw
```

The `//./` corresponds to the Windows syntax of `\\.\` for accessing physical drives.

When you use raw disk partitions, be sure that they have permissions that allow read and write access by the account used for running the MySQL server.

14.5.4. InnoDB Startup Options and System Variables

This section describes the InnoDB-related command options and system variables. System variables that are true or false can be enabled at server startup by naming them, or disabled by using a `skip-` prefix. For example, to enable or disable InnoDB checksums, you can use `--innodb_checksums` or `--skip-innodb_checksums` on the command line, or `innodb_checksums` or `skip-innodb_checksums` in an option file. System variables that take a numeric value can be specified as `--var_name=value` on the command line or as `var_name=value` in option files. For more information on specifying options and system variables, see [Section 4.3, “Specifying Program Options”](#). Many of the system variables can be changed at runtime (see [Section 5.2.4.2, “Dynamic System Variables”](#)).

InnoDB command options:

- `--innodb`
Enables the InnoDB storage engine, if the server was compiled with InnoDB support. Use `--skip-innodb` to disable InnoDB.
- `--innodb_status_file`
Causes InnoDB to create a file named `<datadir>/innodb_status.<pid>` in the MySQL data directory. InnoDB periodically writes the output of `SHOW ENGINE INNODB STATUS` to this file.

InnoDB system variables:

- `innodb_additional_mem_pool_size`
The size in bytes of a memory pool InnoDB uses to store data dictionary information and other internal data structures. The more tables you have in your application, the more memory you need to allocate here. If InnoDB runs out of memory in this pool, it starts to allocate memory from the operating system and writes warning messages to the MySQL error log. The default value is 1MB.
- `innodb_autoextend_increment`
The increment size (in MB) for extending the size of an auto-extending tablespace when it becomes full. The default value is 8.
- `innodb_buffer_pool_ave_mem_mb`
The size of the buffer pool (in MB), if it is placed in the AWE memory. This is relevant only in 32-bit Windows. If your 32-bit Windows operating system supports more than 4GB memory, using so-called “Address Windowing Extensions,” you can allocate the InnoDB buffer pool into the AWE physical memory using this variable. The maximum possible value for this variable is 63000. If it is greater than 0, `innodb_buffer_pool_size` is the window in the 32-bit address space of `mysqld` where InnoDB maps that AWE memory. A good value for `innodb_buffer_pool_size` is 500MB.

To take advantage of AWE memory, you will need to recompile MySQL yourself. The current project settings needed for doing this can be found in the `storage/innobase/os/os0proj.c` source file.

- `innodb_buffer_pool_size`

The size in bytes of the memory buffer `InnoDB` uses to cache data and indexes of its tables. The larger you set this value, the less disk I/O is needed to access data in tables. On a dedicated database server, you may set this to up to 80% of the machine physical memory size. However, do not set it too large because competition for physical memory might cause paging in the operating system.

- `innodb_checksums`

`InnoDB` can use checksum validation on all pages read from the disk to ensure extra fault tolerance against broken hardware or data files. This validation is enabled by default. However, under some rare circumstances (such as when running benchmarks) this extra safety feature is unneeded and can be disabled with `--skip-innodb-checksums`.

- `innodb_commit_concurrency`

The number of threads that can commit at the same time. A value of 0 disables concurrency control.

- `innodb_concurrency_tickets`

The number of threads that can enter `InnoDB` concurrently is determined by the `innodb_thread_concurrency` variable. A thread is placed in a queue when it tries to enter `InnoDB` if the number of threads has already reached the concurrency limit. When a thread is allowed to enter `InnoDB`, it is given a number of “free tickets” equal to the value of `innodb_concurrency_tickets`, and the thread can enter and leave `InnoDB` freely until it has used up its tickets. After that point, the thread again becomes subject to the concurrency check (and possible queuing) the next time it tries to enter `InnoDB`.

- `innodb_data_file_path`

The paths to individual data files and their sizes. The full directory path to each data file is formed by concatenating `innodb_data_home_dir` to each path specified here. The file sizes are specified in MB or GB (1024MB) by appending `M` or `G` to the size value. The sum of the sizes of the files must be at least 10MB. If you do not specify `innodb_data_file_path`, the default behavior is to create a single 10MB auto-extending data file named `ibdata1`. The size limit of individual files is determined by your operating system. You can set the file size to more than 4GB on those operating systems that support big files. You can also use raw disk partitions as data files. See [Section 14.5.3.2, “Using Raw Devices for the Shared Tablespace”](#).

- `innodb_data_home_dir`

The common part of the directory path for all `InnoDB` data files. If you do not set this value, the default is the MySQL data directory. You can specify the value as an empty string, in which case you can use absolute file paths in `innodb_data_file_path`.

- `innodb_doublewrite`

By default, `InnoDB` stores all data twice, first to the doublewrite buffer, and then to the actual data files. This variable is enabled by default. It can be turned off with `--skip-innodb_doublewrite` for benchmarks or cases when top performance is needed rather than concern for data integrity or possible failures.

- `innodb_fast_shutdown`

If you set this variable to 0, `InnoDB` does a full purge and an insert buffer merge before a shutdown. These operations can take minutes, or even hours in extreme cases. If you set this variable to 1, `InnoDB` skips these operations at shutdown. The default value is 1. If you set it to 2, `InnoDB` will just flush its logs and then shut down cold, as if MySQL had crashed; no committed transaction will be lost, but crash recovery will be done at the next startup. A value of 2 cannot be used on NetWare.

- `innodb_file_io_threads`

The number of file I/O threads in `InnoDB`. Normally, this should be left at the default value of 4, but disk I/O on Windows may benefit from a larger number. On Unix, increasing the number has no effect; `InnoDB` always uses the default value.

- `innodb_file_per_table`

If this variable is enabled, `InnoDB` creates each new table using its own `.ibd` file for storing data and indexes, rather than in the shared tablespace. The default is to create tables in the shared tablespace. See [Section 14.5.3.1, “Using Per-Table Tablespaces”](#).

- `innodb_flush_log_at_trx_commit`

When `innodb_flush_log_at_trx_commit` is set to 0, the log buffer is written out to the log file once per second and the flush to disk operation is performed on the log file, but nothing is done at a transaction commit. When this value is 1 (the default), the log buffer is written out to the log file at each transaction commit and the flush to disk operation is performed on the log file. When set to 2, the log buffer is written out to the file at each commit, but the flush to disk operation is not performed on it. However, the flushing on the log file takes place once per second also when the value is 2. Note that the once-per-second flushing is not 100% guaranteed to happen every second, due to process scheduling issues.

The default value of this variable is 1, which is the value that is required for ACID compliance. You can achieve better performance by setting the value different from 1, but then you can lose at most one second worth of transactions in a crash. If you set the value to 0, then any `mysqld` process crash can erase the last second of transactions. If you set the value to 2, then only an operating system crash or a power outage can erase the last second of transactions. However, `InnoDB`'s crash recovery is not affected and thus crash recovery does work regardless of the value. Note that many operating systems and some disk hardware fool the flush-to-disk operation. They may tell `mysqld` that the flush has taken place, even though it has not. Then the durability of transactions is not guaranteed even with the setting 1, and in the worst case a power outage can even corrupt the `InnoDB` database. Using a battery-backed disk cache in the SCSI disk controller or in the disk itself speeds up file flushes, and makes the operation safer. You can also try using the Unix command `hdparm` to disable the caching of disk writes in hardware caches, or use some other command specific to the hardware vendor.

Note: For the greatest possible durability and consistency in a replication setup using `InnoDB` with transactions, you should use `innodb_flush_log_at_trx_commit=1` and `sync_binlog=1` in your master server `my.cnf` file.

- `innodb_flush_method`

If set to `fdatasync` (the default), `InnoDB` uses `fsync()` to flush both the data and log files. If set to `O_DSYNC`, `InnoDB` uses `O_SYNC` to open and flush the log files, but uses `fsync()` to flush the data files. If `O_DIRECT` is specified (available on some GNU/Linux versions), `InnoDB` uses `O_DIRECT` to open the data files, and uses `fsync()` to flush both the data and log files. Note that `InnoDB` uses `fsync()` instead of `fdatasync()`, and it does not use `O_DSYNC` by default because there have been problems with it on many varieties of Unix. This variable is relevant only for Unix. On Windows, the flush method is always `async_unbuffered` and cannot be changed.

Different values of this variable can have a marked effect on `InnoDB` performance. For example, on some systems where `InnoDB` data and log files are located on a SAN, it has been found that setting `innodb_flush_method` to `O_DIRECT` can degrade performance of simple `SELECT` statements by a factor of three.

- `innodb_force_recovery`

The crash recovery mode. Warning: This variable should be set greater than 0 only in an emergency

situation when you want to dump your tables from a corrupt database! Possible values are from 1 to 6. The meanings of these values are described in [Section 14.5.8.1, “Forcing InnoDB Recovery”](#). As a safety measure, InnoDB prevents any changes to its data when this variable is greater than 0.

- `innodb_lock_wait_timeout`

The timeout in seconds an InnoDB transaction may wait for a lock before being rolled back. InnoDB automatically detects transaction deadlocks in its own lock table and rolls back the transaction. InnoDB notices locks set using the `LOCK TABLES` statement. The default is 50 seconds.

- `innodb_locks_unsafe_for_binlog`

This variable controls next-key locking in InnoDB searches and index scans. By default, this variable is 0 (disabled), which means that next-key locking is enabled.

Normally, InnoDB uses an algorithm called *next-key locking*. InnoDB performs row-level locking in such a way that when it searches or scans a table index, it sets shared or exclusive locks on any index records it encounters. Thus, the row-level locks are actually index record locks. The locks that InnoDB sets on index records also affect the “gap” preceding that index record. If a user has a shared or exclusive lock on record *R* in an index, another user cannot insert a new index record immediately before *R* in the order of the index. Enabling this variable causes InnoDB not to use next-key locking in searches or index scans. Next-key locking is still used to ensure foreign key constraints and duplicate key checking. Note that enabling this variable may cause phantom problems: Suppose that you want to read and lock all children from the `child` table with an identifier value larger than 100, with the intention of updating some column in the selected rows later:

```
SELECT * FROM child WHERE id > 100 FOR UPDATE;
```

Suppose that there is an index on the `id` column. The query scans that index starting from the first record where `id` is greater than 100. If the locks set on the index records do not lock out inserts made in the gaps, another client can insert a new row into the table. If you execute the same `SELECT` within the same transaction, you see a new row in the result set returned by the query. This also means that if new items are added to the database, InnoDB does not guarantee serializability. Therefore, if this variable is enabled, InnoDB guarantees at most isolation level `READ COMMITTED`. (Conflict serializability is still guaranteed.)

Enabling this variable has an additional effect: InnoDB in an `UPDATE` or a `DELETE` only locks rows that it updates or deletes. This greatly reduces the probability of deadlocks, but they can happen. Note that enabling this variable still does not allow operations such as `UPDATE` to overtake other similar operations (such as another `UPDATE`) even in the case when they affect different rows. Consider the following example, beginning with this table:

```
CREATE TABLE A(A INT NOT NULL, B INT) ENGINE = InnoDB;
INSERT INTO A VALUES (1,2), (2,3), (3,2), (4,3), (5,2);
COMMIT;
```

Suppose that one client executes these statements:

```
SET AUTOCOMMIT = 0;
UPDATE A SET B = 5 WHERE B = 3;
```

Then suppose that another client executes these statements following those of the first client:

```
SET AUTOCOMMIT = 0;
UPDATE A SET B = 4 WHERE B = 2;
```

In this case, the second `UPDATE` must wait for a commit or rollback of the first `UPDATE`. The first

`UPDATE` has an exclusive lock on row (2,3), and the second `UPDATE` while scanning rows also tries to acquire an exclusive lock for the same row, which it cannot have. This is because `UPDATE` two first acquires an exclusive lock on a row and then determines whether the row belongs to the result set. If not, it releases the unnecessary lock, when the `innodb_locks_unsafe_for_binlog` variable is enabled.

Therefore, `InnoDB` executes `UPDATE` one as follows:

```
x-lock(1,2)
unlock(1,2)
x-lock(2,3)
update(2,3) to (2,5)
x-lock(3,2)
unlock(3,2)
x-lock(4,3)
update(4,3) to (4,5)
x-lock(5,2)
unlock(5,2)
```

`InnoDB` executes `UPDATE` two as follows:

```
x-lock(1,2)
update(1,2) to (1,4)
x-lock(2,3) - wait for query one to commit or rollback
```

- `innodb_log_arch_dir`

The directory where fully written log files would be archived if we used log archiving. If used, the value of this variable should be set the same as `innodb_log_group_home_dir`. However, it is not required.

- `innodb_log_archive`

Whether to log `InnoDB` archive files. This variable is present for historical reasons, but is unused. Recovery from a backup is done by MySQL using its own log files, so there is no need to archive `InnoDB` log files. The default for this variable is 0.

- `innodb_log_buffer_size`

The size in bytes of the buffer that `InnoDB` uses to write to the log files on disk. Sensible values range from 1MB to 8MB. The default is 1MB. A large log buffer allows large transactions to run without a need to write the log to disk before the transactions commit. Thus, if you have big transactions, making the log buffer larger saves disk I/O.

- `innodb_log_file_size`

The size in bytes of each log file in a log group. The combined size of log files must be less than 4GB on 32-bit computers. The default is 5MB. Sensible values range from 1MB to 1/*N*-th of the size of the buffer pool, where *N* is the number of log files in the group. The larger the value, the less checkpoint flush activity is needed in the buffer pool, saving disk I/O. But larger log files also mean that recovery is slower in case of a crash.

- `innodb_log_files_in_group`

The number of log files in the log group. `InnoDB` writes to the files in a circular fashion. The default (and recommended) is 2.

- `innodb_log_group_home_dir`

The directory path to the `InnoDB` log files. It must have the same value as `innodb_log_arch_dir`. If you do not specify any `InnoDB` log variables, the default is to create

two 5MB files names `ib_logfile0` and `ib_logfile1` in the MySQL data directory.

- `innodb_max_dirty_pages_pct`

This is an integer in the range from 0 to 100. The default is 90. The main thread in `InnoDB` tries to write pages from the buffer pool so that the percentage of dirty (not yet written) pages will not exceed this value.

- `innodb_max_purge_lag`

This variable controls how to delay `INSERT`, `UPDATE` and `DELETE` operations when the purge operations are lagging (see [Section 14.5.12, “Implementation of Multi-Versioning”](#)). The default value of this variable is 0, meaning that there are no delays.

The `InnoDB` transaction system maintains a list of transactions that have delete-marked index records by `UPDATE` or `DELETE` operations. Let the length of this list be `purge_lag`. When `purge_lag` exceeds `innodb_max_purge_lag`, each `INSERT`, `UPDATE` and `DELETE` operation is delayed by $((\text{purge_lag}/\text{innodb_max_purge_lag}) \times 10) - 5$ milliseconds. The delay is computed in the beginning of a purge batch, every ten seconds. The operations are not delayed if purge cannot run because of an old consistent read view that could see the rows to be purged.

A typical setting for a problematic workload might be 1 million, assuming that our transactions are small, only 100 bytes in size, and we can allow 100MB of unpurged rows in our tables.

- `innodb_mirrored_log_groups`

The number of identical copies of log groups to keep for the database. Currently, this should be set to 1.

- `innodb_open_files`

This variable is relevant only if you use multiple tablespaces in `InnoDB`. It specifies the maximum number of `.ibd` files that `InnoDB` can keep open at one time. The minimum value is 10. The default is 300.

The file descriptors used for `.ibd` files are for `InnoDB` only. They are independent of those specified by the `--open-files-limit` server option, and do not affect the operation of the table cache.

- `innodb_support_xa`

When set to `ON` or 1 (the default), this variable enables `InnoDB` support for two-phase commit in XA transactions. Enabling `innodb_support_xa` causes an extra disk flush for transaction preparation. If you don't care about using XA, you can disable this variable by setting it to `OFF` or 0 to reduce the number of disk flushes and get better `InnoDB` performance.

- `innodb_sync_spin_loops`

The number of times a thread waits for an `InnoDB` mutex to be freed before the thread is suspended.

- `innodb_table_locks`

`InnoDB` honors `LOCK TABLES`; MySQL does not return from `LOCK TABLE ... WRITE` until all other threads have released all their locks to the table. The default value is 1, which means that `LOCK TABLES` causes `InnoDB` to lock a table internally. In applications using `AUTO COMMIT=1`, `InnoDB`'s internal table locks can cause deadlocks. You can set `innodb_table_locks=0` in the server option file to remove that problem.

- `innodb_thread_concurrency`

`InnoDB` tries to keep the number of operating system threads concurrently inside `InnoDB` less than or equal to the limit given by this variable. If you have performance issues, and `SHOW ENGINE INNODB STATUS` reveals many threads waiting for semaphores, you may have thread “thrashing” and should try setting this variable lower or higher. If you have a computer with many processors and disks, you can try setting the value higher to make better use of your computer's resources. A recommended value is the sum of the number of processors and disks your system has.

The range of this variable is 0 to 1000. A value of 20 or higher is interpreted as infinite concurrency. Infinite means that concurrency checking is disabled and the possibly considerable overhead of acquiring and releasing a mutex is avoided.

The default value is 20 before MySQL 5.1.11, and 8 from 5.1.11 on.

- `innodb_thread_sleep_delay`

How long `InnoDB` threads sleep before joining the `InnoDB` queue, in microseconds. The default value is 10,000. A value of 0 disables sleep.

- `sync_binlog`

If the value of this variable is positive, the MySQL server synchronizes its binary log to disk (`fsync()`) after every `sync_binlog` writes to this binary log. Note that there is one write to the binary log per statement if in autocommit mode, and otherwise one write per transaction. The default value is 0 which does no synchronizing to disk. A value of 1 is the safest choice, because in the event of a crash you lose at most one statement/transaction from the binary log; however, it is also the slowest choice (unless the disk has a battery-backed cache, which makes synchronization very fast).

14.5.5. Creating the `InnoDB` Tablespace

Suppose that you have installed MySQL and have edited your option file so that it contains the necessary `InnoDB` configuration parameters. Before starting MySQL, you should verify that the directories you have specified for `InnoDB` data files and log files exist and that the MySQL server has access rights to those directories. `InnoDB` does not create directories, only files. Check also that you have enough disk space for the data and log files.

It is best to run the MySQL server `mysqld` from the command prompt when you first start the server with `InnoDB` enabled, not from the `mysqld_safe` wrapper or as a Windows service. When you run from a command prompt you see what `mysqld` prints and what is happening. On Unix, just invoke `mysqld`. On Windows, use the `--console` option.

When you start the MySQL server after initially configuring `InnoDB` in your option file, `InnoDB` creates your data files and log files, and prints something like this:

```
InnoDB: The first specified datafile /home/heikki/data/ibdata1
did not exist:
InnoDB: a new database to be created!
InnoDB: Setting file /home/heikki/data/ibdata1 size to 134217728
InnoDB: Database physically writes the file full: wait...
InnoDB: datafile /home/heikki/data/ibdata2 did not exist:
new to be created
InnoDB: Setting file /home/heikki/data/ibdata2 size to 262144000
InnoDB: Database physically writes the file full: wait...
InnoDB: Log file /home/heikki/data/logs/ib_logfile0 did not exist:
new to be created
InnoDB: Setting log file /home/heikki/data/logs/ib_logfile0 size
to 5242880
InnoDB: Log file /home/heikki/data/logs/ib_logfile1 did not exist:
new to be created
InnoDB: Setting log file /home/heikki/data/logs/ib_logfile1 size
```

```
to 5242880
InnoDB: Doublewrite buffer not found: creating new
InnoDB: Doublewrite buffer created
InnoDB: Creating foreign key constraint system tables
InnoDB: Foreign key constraint system tables created
InnoDB: Started
mysqld: ready for connections
```

At this point **InnoDB** has initialized its tablespace and log files. You can connect to the MySQL server with the usual MySQL client programs like `mysql`. When you shut down the MySQL server with `mysqladmin shutdown`, the output is like this:

```
010321 18:33:34 mysqld: Normal shutdown
010321 18:33:34 mysqld: Shutdown Complete
InnoDB: Starting shutdown...
InnoDB: Shutdown completed
```

You can look at the data file and log directories and you see the files created there. The log directory also contains a small file named `ib_arch_log_0000000000`. That file resulted from the database creation, after which **InnoDB** switched off log archiving. When MySQL is started again, the data files and log files have been created already, so the output is much briefer:

```
InnoDB: Started
mysqld: ready for connections
```

If you add the `innodb_file_per_table` option to `my.cnf`, **InnoDB** stores each table in its own `.ibd` file in the same MySQL database directory where the `.frm` file is created. See [Section 14.5.3.1, “Using Per-Table Tablespaces”](#).

14.5.5.1. Dealing with **InnoDB** Initialization Problems

If **InnoDB** prints an operating system error during a file operation, usually the problem has one of the following causes:

- You did not create the **InnoDB** data file directory or the **InnoDB** log directory.
- `mysqld` does not have access rights to create files in those directories.
- `mysqld` cannot read the proper `my.cnf` or `my.ini` option file, and consequently does not see the options that you specified.
- The disk is full or a disk quota is exceeded.
- You have created a subdirectory whose name is equal to a data file that you specified, so the name cannot be used as a filename.
- There is a syntax error in the `innodb_data_home_dir` or `innodb_data_file_path` value.

If something goes wrong when **InnoDB** attempts to initialize its tablespace or its log files, you should delete all files created by **InnoDB**. This means all `ibdata` files and all `ib_logfile` files. In case you have already created some **InnoDB** tables, delete the corresponding `.frm` files for these tables (and any `.ibd` files if you are using multiple tablespaces) from the MySQL database directories as well. Then you can try the **InnoDB** database creation again. It is best to start the MySQL server from a command prompt so that you see what is happening.

14.5.6. Creating and Using **InnoDB** Tables

To create an `InnoDB` table, specify an `ENGINE = InnoDB` option in the `CREATE TABLE` statement:

```
CREATE TABLE customers (a INT, b CHAR (20), INDEX (a)) ENGINE=InnoDB;
```

The statement creates a table and an index on column `a` in the `InnoDB` tablespace that consists of the data files that you specified in `my.cnf`. In addition, MySQL creates a file `customers.frm` in the `test` directory under the MySQL database directory. Internally, `InnoDB` adds an entry for the table to its own data dictionary. The entry includes the database name. For example, if `test` is the database in which the `customers` table is created, the entry is for `'test/customers'`. This means you can create a table of the same name `customers` in some other database, and the table names do not collide inside `InnoDB`.

You can query the amount of free space in the `InnoDB` tablespace by issuing a `SHOW TABLE STATUS` statement for any `InnoDB` table. The amount of free space in the tablespace appears in the `Comment` section in the output of `SHOW TABLE STATUS`. For example:

```
SHOW TABLE STATUS FROM test LIKE 'customers'
```

Note that the statistics `SHOW` displays for `InnoDB` tables are only approximate. They are used in SQL optimization. Table and index reserved sizes in bytes are accurate, though.

14.5.6.1. How to Use Transactions in `InnoDB` with Different APIs

By default, each client that connects to the MySQL server begins with autocommit mode enabled, which automatically commits every SQL statement as you execute it. To use multiple-statement transactions, you can switch autocommit off with the SQL statement `SET AUTOCOMMIT = 0` and use `COMMIT` and `ROLLBACK` to commit or roll back your transaction. If you want to leave autocommit on, you can enclose your transactions within `START TRANSACTION` and either `COMMIT` or `ROLLBACK`. The following example shows two transactions. The first is committed; the second is rolled back.

```
shell> mysql test

mysql> CREATE TABLE CUSTOMER (A INT, B CHAR (20), INDEX (A))
-> ENGINE=InnoDB;
Query OK, 0 rows affected (0.00 sec)
mysql> START TRANSACTION;
Query OK, 0 rows affected (0.00 sec)
mysql> INSERT INTO CUSTOMER VALUES (10, 'Heikki');
Query OK, 1 row affected (0.00 sec)
mysql> COMMIT;
Query OK, 0 rows affected (0.00 sec)
mysql> SET AUTOCOMMIT=0;
Query OK, 0 rows affected (0.00 sec)
mysql> INSERT INTO CUSTOMER VALUES (15, 'John');
Query OK, 1 row affected (0.00 sec)
mysql> ROLLBACK;
Query OK, 0 rows affected (0.00 sec)
mysql> SELECT * FROM CUSTOMER;
+-----+-----+
| A     | B     |
+-----+-----+
| 10   | Heikki |
+-----+-----+
1 row in set (0.00 sec)
mysql>
```

In APIs such as PHP, Perl DBI, JDBC, ODBC, or the standard C call interface of MySQL, you can send transaction control statements such as `COMMIT` to the MySQL server as strings just like any other SQL statements such as `SELECT` or `INSERT`. Some APIs also offer separate special transaction commit and rollback functions or methods.

14.5.6.2. Converting `MyISAM` Tables to `InnoDB`

Important: Do not convert MySQL system tables in the `mysql` database (such as `user` or `host`) to the `InnoDB` type. This is an unsupported operation. The system tables must always be of the `MyISAM` type.

If you want all your (non-system) tables to be created as `InnoDB` tables, you can simply add the line `default-storage-engine=innodb` to the `[mysqld]` section of your server option file.

`InnoDB` does not have a special optimization for separate index creation the way the `MyISAM` storage engine does. Therefore, it does not pay to export and import the table and create indexes afterward. The fastest way to alter a table to `InnoDB` is to do the inserts directly to an `InnoDB` table. That is, use `ALTER TABLE ... ENGINE=INNODB`, or create an empty `InnoDB` table with identical definitions and insert the rows with `INSERT INTO ... SELECT * FROM ...`.

If you have `UNIQUE` constraints on secondary keys, you can speed up a table import by turning off the uniqueness checks temporarily during the import operation:

```
SET UNIQUE_CHECKS=0;
... import operation ...
SET UNIQUE_CHECKS=1;
```

For big tables, this saves a lot of disk I/O because `InnoDB` can then use its insert buffer to write secondary index records as a batch. Be certain that the data contains no duplicate keys. `UNIQUE_CHECKS` allows but does not require storage engines to ignore duplicate keys.

To get better control over the insertion process, it might be good to insert big tables in pieces:

```
INSERT INTO newtable SELECT * FROM oldtable
WHERE yourkey > something AND yourkey <= somethingelse;
```

After all records have been inserted, you can rename the tables.

During the conversion of big tables, you should increase the size of the `InnoDB` buffer pool to reduce disk I/O. Do not use more than 80% of the physical memory, though. You can also increase the sizes of the `InnoDB` log files.

Make sure that you do not fill up the tablespace: `InnoDB` tables require a lot more disk space than `MyISAM` tables. If an `ALTER TABLE` operation runs out of space, it starts a rollback, and that can take hours if it is disk-bound. For inserts, `InnoDB` uses the insert buffer to merge secondary index records to indexes in batches. That saves a lot of disk I/O. For rollback, no such mechanism is used, and the rollback can take 30 times longer than the insertion.

In the case of a runaway rollback, if you do not have valuable data in your database, it may be advisable to kill the database process rather than wait for millions of disk I/O operations to complete. For the complete procedure, see [Section 14.5.8.1, “Forcing InnoDB Recovery”](#).

14.5.6.3. How `AUTO_INCREMENT` Columns Work in `InnoDB`

If you specify an `AUTO_INCREMENT` column for an `InnoDB` table, the table handle in the `InnoDB` data dictionary contains a special counter called the auto-increment counter that is used in assigning new values for the column. This counter is stored only in main memory, not on disk.

`InnoDB` uses the following algorithm to initialize the auto-increment counter for a table `T` that contains an `AUTO_INCREMENT` column named `ai_col`: After a server startup, for the first insert into a table `T`, `InnoDB` executes the equivalent of this statement:

```
SELECT MAX(ai_col) FROM T FOR UPDATE;
```

`InnoDB` increments by one the value retrieved by the statement and assigns it to the column and to the auto-increment counter for the table. If the table is empty, `InnoDB` uses the value `1`. If a user invokes a

`SHOW TABLE STATUS` statement that displays output for the table `T` and the auto-increment counter has not been initialized, `InnoDB` initializes but does not increment the value and stores it for use by later inserts. Note that this initialization uses a normal exclusive-locking read on the table and the lock lasts to the end of the transaction.

`InnoDB` follows the same procedure for initializing the auto-increment counter for a freshly created table.

After the auto-increment counter has been initialized, if a user does not explicitly specify a value for an `AUTO_INCREMENT` column, `InnoDB` increments the counter by one and assigns the new value to the column. If the user inserts a row that explicitly specifies the column value, and the value is bigger than the current counter value, the counter is set to the specified column value.

You may see gaps in the sequence of values assigned to the `AUTO_INCREMENT` column if you roll back transactions that have generated numbers using the counter.

If a user specifies `NULL` or `0` for the `AUTO_INCREMENT` column in an `INSERT`, `InnoDB` treats the row as if the value had not been specified and generates a new value for it.

The behavior of the auto-increment mechanism is not defined if a user assigns a negative value to the column or if the value becomes bigger than the maximum integer that can be stored in the specified integer type.

When accessing the auto-increment counter, `InnoDB` uses a special table-level `AUTO-INC` lock that it keeps to the end of the current SQL statement, not to the end of the transaction. The special lock release strategy was introduced to improve concurrency for inserts into a table containing an `AUTO_INCREMENT` column. Nevertheless, two transactions cannot have the `AUTO-INC` lock on the same table simultaneously, which can have a performance impact if the `AUTO-INC` lock is held for a long time. That might be the case for a statement such as `INSERT INTO t1 ... SELECT ... FROM t2` that inserts all rows from one table into another.

`InnoDB` uses the in-memory auto-increment counter as long as the server runs. When the server is stopped and restarted, `InnoDB` reinitializes the counter for each table for the first `INSERT` to the table, as described earlier.

`InnoDB` supports the `AUTO_INCREMENT = N` table option in `CREATE TABLE` and `ALTER TABLE` statements, to set the initial counter value or alter the current counter value. The effect of this option is canceled by a server restart, for reasons discussed earlier in this section.

14.5.6.4. FOREIGN KEY Constraints

`InnoDB` also supports foreign key constraints. The syntax for a foreign key constraint definition in `InnoDB` looks like this:

```
[CONSTRAINT symbol] FOREIGN KEY [id] (index_col_name, ...)
REFERENCES tbl_name (index_col_name, ...)
[ON DELETE {RESTRICT | CASCADE | SET NULL | NO ACTION}]
[ON UPDATE {RESTRICT | CASCADE | SET NULL | NO ACTION}]
```

Foreign keys definitions are subject to the following conditions:

- Both tables must be `InnoDB` tables and they must not be `TEMPORARY` tables.
- In the referencing table, there must be an index where the foreign key columns are listed as the *first* columns in the same order. Such an index is created on the referencing table automatically if it does not exist.
- In the referenced table, there must be an index where the referenced columns are listed as the *first* columns in the same order.

- Index prefixes on foreign key columns are not supported. One consequence of this is that `BLOB` and `TEXT` columns cannot be included in a foreign key, because indexes on those columns must always include a prefix length.
- If the `CONSTRAINT symbol` clause is given, the `symbol` value must be unique in the database. If the clause is not given, `InnoDB` creates the name automatically.

`InnoDB` rejects any `INSERT` or `UPDATE` operation that attempts to create a foreign key value in a child table if there is no a matching candidate key value in the parent table. The action `InnoDB` takes for any `UPDATE` or `DELETE` operation that attempts to update or delete a candidate key value in the parent table that has some matching rows in the child table is dependent on the *referential action* specified using `ON UPDATE` and `ON DELETE` subclauses of the `FOREIGN KEY` clause. When the user attempts to delete or update a row from a parent table, and there are one or more matching rows in the child table, `InnoDB` supports five options regarding the action to be taken:

- `CASCADE`: Delete or update the row from the parent table and automatically delete or update the matching rows in the child table. Both `ON DELETE CASCADE` and `ON UPDATE CASCADE` are supported. Between two tables, you should not define several `ON UPDATE CASCADE` clauses that act on the same column in the parent table or in the child table.
- `SET NULL`: Delete or update the row from the parent table and set the foreign key column or columns in the child table to `NULL`. This is valid only if the foreign key columns do not have the `NOT NULL` qualifier specified. Both `ON DELETE SET NULL` and `ON UPDATE SET NULL` clauses are supported.
- `NO ACTION`: In standard SQL, `NO ACTION` means *no action* in the sense that an attempt to delete or update a primary key value is not allowed to proceed if there is a related foreign key value in the referenced table. `InnoDB` rejects the delete or update operation for the parent table.
- `RESTRICT`: Rejects the delete or update operation for the parent table. `NO ACTION` and `RESTRICT` are the same as omitting the `ON DELETE` or `ON UPDATE` clause. (Some database systems have deferred checks, and `NO ACTION` is a deferred check. In MySQL, foreign key constraints are checked immediately, so `NO ACTION` and `RESTRICT` are the same.)
- `SET DEFAULT`: This action is recognized by the parser, but `InnoDB` rejects table definitions containing `ON DELETE SET DEFAULT` or `ON UPDATE SET DEFAULT` clauses.

Note that `InnoDB` supports foreign key references within a table. In these cases, “child table records” really refers to dependent records within the same table.

`InnoDB` requires indexes on foreign keys and referenced keys so that foreign key checks can be fast and not require a table scan. The index on the foreign key is created automatically. This is in contrast to some older versions, in which indexes had to be created explicitly or the creation of foreign key constraints would fail.

Corresponding columns in the foreign key and the referenced key must have similar internal data types inside `InnoDB` so that they can be compared without a type conversion. *The size and sign of integer types must be the same.* The length of string types need not be the same. If you specify a `SET NULL` action, *make sure that you have not declared the columns in the child table as `NOT NULL`.*

If MySQL reports an error number 1005 from a `CREATE TABLE` statement, and the error message refers to `errno 150`, table creation failed because a foreign key constraint was not correctly formed. Similarly, if an `ALTER TABLE` fails and it refers to `errno 150`, that means a foreign key definition would be incorrectly formed for the altered table. You can use `SHOW ENGINE INNODB STATUS` to display a detailed explanation of the most recent `InnoDB` foreign key error in the server.

Note: `InnoDB` does not check foreign key constraints on those foreign key or referenced key values that contain a `NULL` column.

Note: Currently, triggers are not activated by cascaded foreign key actions.

You cannot create a table with a column name that matches the name of an internal `InnoDB` column (including `DB_ROW_ID`, `DB_TRX_ID`, `DB_ROLL_PTR` and `DB_MIX_ID`). In versions of MySQL before 5.1.10 this would cause a crash, since 5.1.10 the server will report error 1005 and refers to `errno - 1` in the error message.

Deviation from SQL standards: If there are several rows in the parent table that have the same referenced key value, `InnoDB` acts in foreign key checks as if the other parent rows with the same key value do not exist. For example, if you have defined a `RESTRICT` type constraint, and there is a child row with several parent rows, `InnoDB` does not allow the deletion of any of those parent rows.

`InnoDB` performs cascading operations through a depth-first algorithm, based on records in the indexes corresponding to the foreign key constraints.

Deviation from SQL standards: A `FOREIGN KEY` constraint that references a non-`UNIQUE` key is not standard SQL. It is an `InnoDB` extension to standard SQL.

Deviation from SQL standards: If `ON UPDATE CASCADE` or `ON UPDATE SET NULL` recurses to update the *same table* it has previously updated during the cascade, it acts like `RESTRICT`. This means that you cannot use self-referential `ON UPDATE CASCADE` or `ON UPDATE SET NULL` operations. This is to prevent infinite loops resulting from cascaded updates. A self-referential `ON DELETE SET NULL`, on the other hand, is possible, as is a self-referential `ON DELETE CASCADE`. Cascading operations may not be nested more than 15 levels deep.

Deviation from SQL standards: Like MySQL in general, in an SQL statement that inserts, deletes, or updates many rows, `InnoDB` checks `UNIQUE` and `FOREIGN KEY` constraints row-by-row. According to the SQL standard, the default behavior should be deferred checking. That is, constraints are only checked after the *entire SQL statement* has been processed. Until `InnoDB` implements deferred constraint checking, some things will be impossible, such as deleting a record that refers to itself via a foreign key.

Here is a simple example that relates `parent` and `child` tables through a single-column foreign key:

```
CREATE TABLE parent (id INT NOT NULL,
                     PRIMARY KEY (id)
) ENGINE=INNODB;
CREATE TABLE child (id INT, parent_id INT,
                    INDEX par_ind (parent_id),
                    FOREIGN KEY (parent_id) REFERENCES parent(id)
                    ON DELETE CASCADE
) ENGINE=INNODB;
```

A more complex example in which a `product_order` table has foreign keys for two other tables. One foreign key references a two-column index in the `product` table. The other references a single-column index in the `customer` table:

```
CREATE TABLE product (category INT NOT NULL, id INT NOT NULL,
                      price DECIMAL,
                      PRIMARY KEY(category, id)) ENGINE=INNODB;
CREATE TABLE customer (id INT NOT NULL,
                       PRIMARY KEY (id)) ENGINE=INNODB;
CREATE TABLE product_order (no INT NOT NULL AUTO_INCREMENT,
                             product_category INT NOT NULL,
                             product_id INT NOT NULL,
                             customer_id INT NOT NULL,
                             PRIMARY KEY(no),
                             INDEX (product_category, product_id),
                             FOREIGN KEY (product_category, product_id)
                             REFERENCES product(category, id)
                             ON UPDATE CASCADE ON DELETE RESTRICT,
```

```
INDEX (customer_id),
FOREIGN KEY (customer_id)
REFERENCES customer(id) ENGINE=INNODB;
```

InnoDB allows you to add a new foreign key constraint to a table by using `ALTER TABLE`:

```
ALTER TABLE tbl_name
ADD [CONSTRAINT symbol] FOREIGN KEY [id] (index_col_name, ...)
REFERENCES tbl_name (index_col_name, ...)
[ON DELETE {RESTRICT | CASCADE | SET NULL | NO ACTION}]
[ON UPDATE {RESTRICT | CASCADE | SET NULL | NO ACTION}]
```

Remember to create the required indexes first. You can also add a self-referential foreign key constraint to a table using `ALTER TABLE`.

InnoDB also supports the use of `ALTER TABLE` to drop foreign keys:

```
ALTER TABLE tbl_name DROP FOREIGN KEY fk_symbol;
```

If the `FOREIGN KEY` clause included a `CONSTRAINT` name when you created the foreign key, you can refer to that name to drop the foreign key. Otherwise, the `fk_symbol` value is internally generated by InnoDB when the foreign key is created. To find out the symbol value when you want to drop a foreign key, use the `SHOW CREATE TABLE` statement. For example:

```
mysql> SHOW CREATE TABLE ibtest11c\G
***** 1. row *****
      Table: ibtest11c
Create Table: CREATE TABLE `ibtest11c` (
  `A` int(11) NOT NULL auto_increment,
  `D` int(11) NOT NULL default '0',
  `B` varchar(200) NOT NULL default '',
  `C` varchar(175) default NULL,
  PRIMARY KEY (`A`,`D`,`B`),
  KEY `B` (`B`,`C`),
  KEY `C` (`C`),
  CONSTRAINT `0_38775` FOREIGN KEY (`A`, `D`)
REFERENCES `ibtest11a` (`A`, `D`)
ON DELETE CASCADE ON UPDATE CASCADE,
  CONSTRAINT `0_38776` FOREIGN KEY (`B`, `C`)
REFERENCES `ibtest11a` (`B`, `C`)
ON DELETE CASCADE ON UPDATE CASCADE
) ENGINE=INNODB CHARSET=latin1
1 row in set (0.01 sec)

mysql> ALTER TABLE ibtest11c DROP FOREIGN KEY `0_38775`;
```

You cannot add a foreign key and drop a foreign key in separate clauses of a single `ALTER TABLE` statement. Separate statements are required.

The InnoDB parser allows table and column identifiers in a `FOREIGN KEY ... REFERENCES ...` clause to be quoted within backticks. (Alternatively, double quotes can be used if the `ANSI_QUOTES` SQL mode is enabled.) The InnoDB parser also takes into account the setting of the `lower_case_table_names` system variable.

InnoDB returns a table's foreign key definitions as part of the output of the `SHOW CREATE TABLE` statement:

```
SHOW CREATE TABLE tbl_name;
```

`mysqldump` also produces correct definitions of tables to the dump file, and does not forget about the foreign keys.

You can also display the foreign key constraints for a table like this:

```
SHOW TABLE STATUS FROM db_name LIKE 'tbl_name';
```

The foreign key constraints are listed in the `Comment` column of the output.

When performing foreign key checks, InnoDB sets shared row-level locks on child or parent records it has to look at. InnoDB checks foreign key constraints immediately; the check is not deferred to transaction commit.

To make it easier to reload dump files for tables that have foreign key relationships, `mysqldump` automatically includes a statement in the dump output to set `FOREIGN_KEY_CHECKS` to 0. This avoids problems with tables having to be reloaded in a particular order when the dump is reloaded. It is also possible to set this variable manually:

```
mysql> SET FOREIGN_KEY_CHECKS = 0;
mysql> SOURCE dump_file_name;
mysql> SET FOREIGN_KEY_CHECKS = 1;
```

This allows you to import the tables in any order if the dump file contains tables that are not correctly ordered for foreign keys. It also speeds up the import operation. Setting `FOREIGN_KEY_CHECKS` to 0 can also be useful for ignoring foreign key constraints during `LOAD DATA` and `ALTER TABLE` operations. However, even if `FOREIGN_KEY_CHECKS=0`, InnoDB does not allow the creation of a foreign key constraint where a column references a non-matching column type.

InnoDB does not allow you to drop a table that is referenced by a `FOREIGN KEY` constraint, unless you do `SET FOREIGN_KEY_CHECKS=0`. When you drop a table, the constraints that were defined in its create statement are also dropped.

If you re-create a table that was dropped, it must have a definition that conforms to the foreign key constraints referencing it. It must have the right column names and types, and it must have indexes on the referenced keys, as stated earlier. If these are not satisfied, MySQL returns error number 1005 and refers to errno 150 in the error message.

14.5.6.5. InnoDB and MySQL Replication

MySQL replication works for InnoDB tables as it does for MyISAM tables. It is also possible to use replication in a way where the storage engine on the slave is not the same as the original storage engine on the master. For example, you can replicate modifications to an InnoDB table on the master to a MyISAM table on the slave.

To set up a new slave for a master, you have to make a copy of the InnoDB tablespace and the log files, as well as the `.frm` files of the InnoDB tables, and move the copies to the slave. If the `innodb_file_per_table` variable is enabled, you must also copy the `.ibd` files as well. For the proper procedure to do this, see [Section 14.5.8, “Backing Up and Recovering an InnoDB Database”](#).

If you can shut down the master or an existing slave, you can take a cold backup of the InnoDB tablespace and log files and use that to set up a slave. To make a new slave without taking down any server you can also use the non-free (commercial) [InnoDB Hot Backup tool](#) [<http://www.innodb.com/order.html>].

You cannot set up replication for InnoDB using the `LOAD TABLE FROM MASTER` statement, which works only for MyISAM tables. There are two possible workarounds:

- Dump the table on the master and import the dump file into the slave.
- Use `ALTER TABLE tbl_name ENGINE=MyISAM` on the master before setting up replication with `LOAD TABLE tbl_name FROM MASTER`, and then use `ALTER TABLE` to convert the master table back to InnoDB afterward. However, this should not be done for tables that have for-

own key definitions because the definitions will be lost.

Transactions that fail on the master do not affect replication at all. MySQL replication is based on the binary log where MySQL writes SQL statements that modify data. A transaction that fails (for example, because of a foreign key violation, or because it is rolled back) is not written to the binary log, so it is not sent to slaves. See [Section 13.4.1, “START TRANSACTION, COMMIT, and ROLLBACK Syntax”](#).

14.5.7. Adding and Removing InnoDB Data and Log Files

This section describes what you can do when your InnoDB tablespace runs out of room or when you want to change the size of the log files.

The easiest way to increase the size of the InnoDB tablespace is to configure it from the beginning to be auto-extending. Specify the `autoextend` attribute for the last data file in the tablespace definition. Then InnoDB increases the size of that file automatically in 8MB increments when it runs out of space. The increment size can be changed by setting the value of the `innodb_autoextend_increment` system variable, which is measured in MB.

Alternatively, you can increase the size of your tablespace by adding another data file. To do this, you have to shut down the MySQL server, change the tablespace configuration to add a new data file to the end of `innodb_data_file_path`, and start the server again.

If your last data file was defined with the keyword `autoextend`, the procedure for reconfiguring the tablespace must take into account the size to which the last data file has grown. Obtain the size of the data file, round it down to the closest multiple of 1024×1024 bytes (= 1MB), and specify the rounded size explicitly in `innodb_data_file_path`. Then you can add another data file. Remember that only the last data file in the `innodb_data_file_path` can be specified as auto-extending.

As an example, assume that the tablespace has just one auto-extending data file `ibdata1`:

```
innodb_data_home_dir =  
innodb_data_file_path = /ibdata/ibdata1:10M:autoextend
```

Suppose that this data file, over time, has grown to 988MB. Here is the configuration line after modifying the original data file to not be auto-extending and adding another auto-extending data file:

```
innodb_data_home_dir =  
innodb_data_file_path = /ibdata/ibdata1:988M;/disk2/ibdata2:50M:autoextend
```

When you add a new file to the tablespace configuration, make sure that it does not exist. InnoDB will create and initialize the file when you restart the server.

Currently, you cannot remove a data file from the tablespace. To decrease the size of your tablespace, use this procedure:

1. Use `mysqldump` to dump all your InnoDB tables.
2. Stop the server.
3. Remove all the existing tablespace files.
4. Configure a new tablespace.
5. Restart the server.
6. Import the dump files.

If you want to change the number or the size of your [InnoDB](#) log files, use the following instructions. The procedure to use depends on the value of `innodb_fast_shutdown`:

- If `innodb_fast_shutdown` is not set to 2: You must stop the MySQL server and make sure that it shuts down without errors (to ensure that there is no information for outstanding transactions in the logs). Then copy the old log files into a safe place just in case something went wrong in the shutdown and you need them to recover the tablespace. Delete the old log files from the log file directory, edit `my.cnf` to change the log file configuration, and start the MySQL server again. `mysqld` sees that no log files exist at startup and tells you that it is creating new ones.
- If `innodb_fast_shutdown` is set to 2: You should shut down the server, set `innodb_fast_shutdown` to 1, and restart the server. The server should be allowed to recover. Then you should shut down the server again and follow the procedure described in the preceding item to change [InnoDB](#) log file size. Set `innodb_fast_shutdown` back to 2 and restart the server.

14.5.8. Backing Up and Recovering an [InnoDB](#) Database

The key to safe database management is making regular backups.

[InnoDB Hot Backup](#) is an online backup tool you can use to backup your [InnoDB](#) database while it is running. [InnoDB Hot Backup](#) does not require you to shut down your database and it does not set any locks or disturb your normal database processing. [InnoDB Hot Backup](#) is a non-free (commercial) add-on tool with an annual license fee of €390 per computer on which the MySQL server is run. See the [InnoDB Hot Backup home page](#) [<http://www.innodb.com/order.html>] for detailed information and screenshots.

If you are able to shut down your MySQL server, you can make a binary backup that consists of all files used by [InnoDB](#) to manage its tables. Use the following procedure:

1. Shut down your MySQL server and make sure that it shuts down without errors.
2. Copy all your data files (`ibdata` files and `.ibd` files) into a safe place.
3. Copy all your `ib_logfile` files to a safe place.
4. Copy your `my.cnf` configuration file or files to a safe place.
5. Copy all the `.frm` files for your [InnoDB](#) tables to a safe place.

Replication works with [InnoDB](#) tables, so you can use MySQL replication capabilities to keep a copy of your database at database sites requiring high availability.

In addition to making binary backups as just described, you should also regularly make dumps of your tables with `mysqldump`. The reason for this is that a binary file might be corrupted without you noticing it. Dumped tables are stored into text files that are human-readable, so spotting table corruption becomes easier. Also, because the format is simpler, the chance for serious data corruption is smaller. `mysqldump` also has a `--single-transaction` option that you can use to make a consistent snapshot without locking out other clients.

To be able to recover your [InnoDB](#) database to the present from the binary backup just described, you have to run your MySQL server with binary logging turned on. Then you can apply the binary log to the backup database to achieve point-in-time recovery:

```
mysqlbinlog yourhostname-bin.123 | mysql
```

To recover from a crash of your MySQL server, the only requirement is to restart it. [InnoDB](#) automatically checks the logs and performs a roll-forward of the database to the present. [InnoDB](#) automatically rolls back uncommitted transactions that were present at the time of the crash. During recovery, [mysqld](#) displays output something like this:

```
InnoDB: Database was not shut down normally.
InnoDB: Starting recovery from log files...
InnoDB: Starting log scan based on checkpoint at
InnoDB: log sequence number 0 13674004
InnoDB: Doing recovery: scanned up to log sequence number 0 13739520
InnoDB: Doing recovery: scanned up to log sequence number 0 13805056
InnoDB: Doing recovery: scanned up to log sequence number 0 13870592
InnoDB: Doing recovery: scanned up to log sequence number 0 13936128
...
InnoDB: Doing recovery: scanned up to log sequence number 0 20555264
InnoDB: Doing recovery: scanned up to log sequence number 0 20620800
InnoDB: Doing recovery: scanned up to log sequence number 0 20664692
InnoDB: 1 uncommitted transaction(s) which must be rolled back
InnoDB: Starting rollback of uncommitted transactions
InnoDB: Rolling back trx no 16745
InnoDB: Rolling back of trx no 16745 completed
InnoDB: Rollback of uncommitted transactions completed
InnoDB: Starting an apply batch of log records to the database...
InnoDB: Apply batch completed
InnoDB: Started
mysqld: ready for connections
```

If your database gets corrupted or your disk fails, you have to do the recovery from a backup. In the case of corruption, you should first find a backup that is not corrupted. After restoring the base backup, do the recovery from the binary log files using [mysqlbinlog](#) and [mysql](#) to restore the changes performed after the backup was made.

In some cases of database corruption it is enough just to dump, drop, and re-create one or a few corrupt tables. You can use the [CHECK TABLE](#) SQL statement to check whether a table is corrupt, although [CHECK TABLE](#) naturally cannot detect every possible kind of corruption. You can use [innodb_tablespace_monitor](#) to check the integrity of the file space management inside the tablespace files.

In some cases, apparent database page corruption is actually due to the operating system corrupting its own file cache, and the data on disk may be okay. It is best first to try restarting your computer. Doing so may eliminate errors that appeared to be database page corruption.

14.5.8.1. Forcing [InnoDB](#) Recovery

If there is database page corruption, you may want to dump your tables from the database with [SELECT INTO outfile](#). Usually, most of the data obtained in this way is intact. Even so, the corruption may cause [SELECT * FROM tbl_name](#) statements or [InnoDB](#) background operations to crash or assert, or even to cause [InnoDB](#) roll-forward recovery to crash. However, you can force the [InnoDB](#) storage engine to start up while preventing background operations from running, so that you are able to dump your tables. For example, you can add the following line to the [\[mysqld\]](#) section of your option file before restarting the server:

```
[mysqld]
innodb_force_recovery = 4
```

The allowable non-zero values for [innodb_force_recovery](#) follow. A larger number includes all precautions of smaller numbers. If you are able to dump your tables with an option value of at most 4, then you are relatively safe that only some data on corrupt individual pages is lost. A value of 6 is more drastic because database pages are left in an obsolete state, which in turn may introduce more corruption into B-trees and other database structures.

- 1 (SRV_FORCE_IGNORE_CORRUPT)

Let the server run even if it detects a corrupt page. Try to make `SELECT * FROM tbl_name` jump over corrupt index records and pages, which helps in dumping tables.

- 2 (SRV_FORCE_NO_BACKGROUND)

Prevent the main thread from running. If a crash would occur during the purge operation, this recovery value prevents it.

- 3 (SRV_FORCE_NO_TRX_UNDO)

Do not run transaction rollbacks after recovery.

- 4 (SRV_FORCE_NO_IBUF_MERGE)

Prevent also insert buffer merge operations. If they would cause a crash, do not do them. Do not calculate table statistics.

- 5 (SRV_FORCE_NO_UNDO_LOG_SCAN)

Do not look at undo logs when starting the database: InnoDB treats even incomplete transactions as committed.

- 6 (SRV_FORCE_NO_LOG_REDO)

Do not do the log roll-forward in connection with recovery.

You can `SELECT` from tables to dump them, or `DROP` or `CREATE` tables even if forced recovery is used. If you know that a given table is causing a crash on rollback, you can drop it. You can also use this to stop a runaway rollback caused by a failing mass import or `ALTER TABLE`. You can kill the `mysqld` process and set `innodb_force_recovery` to 3 to bring the database up without the rollback, then `DROP` the table that is causing the runaway rollback.

The database must not otherwise be used with any non-zero value of `innodb_force_recovery`. As a safety measure, InnoDB prevents users from performing `INSERT`, `UPDATE`, or `DELETE` operations when `innodb_force_recovery` is greater than 0.

14.5.8.2. Checkpoints

InnoDB implements a checkpoint mechanism known as “fuzzy” checkpointing. InnoDB flushes modified database pages from the buffer pool in small batches. There is no need to flush the buffer pool in one single batch, which would in practice stop processing of user SQL statements during the checkpointing process.

During crash recovery, InnoDB looks for a checkpoint label written to the log files. It knows that all modifications to the database before the label are present in the disk image of the database. Then InnoDB scans the log files forward from the checkpoint, applying the logged modifications to the database.

InnoDB writes to its log files on a rotating basis. All committed modifications that make the database pages in the buffer pool different from the images on disk must be available in the log files in case InnoDB has to do a recovery. This means that when InnoDB starts to reuse a log file, it has to make sure that the database page images on disk contain the modifications logged in the log file that InnoDB is going to reuse. In other words, InnoDB must create a checkpoint and this often involves flushing of modified database pages to disk.

The preceding description explains why making your log files very large may save disk I/O in check-

pointing. It often makes sense to set the total size of the log files as big as the buffer pool or even bigger. The drawback of using large log files is that crash recovery can take longer because there is more logged information to apply to the database.

14.5.9. Moving an InnoDB Database to Another Machine

On Windows, InnoDB always stores database and table names internally in lowercase. To move databases in a binary format from Unix to Windows or from Windows to Unix, you should have all table and database names in lowercase. A convenient way to accomplish this is to add the following line to the `[mysqld]` section of your `my.cnf` or `my.ini` file before creating any databases or tables:

```
[mysqld]
lower_case_table_names=1
```

Like MyISAM data files, InnoDB data and log files are binary-compatible on all platforms having the same floating-point number format. You can move an InnoDB database simply by copying all the relevant files listed in Section 14.5.8, “Backing Up and Recovering an InnoDB Database”. If the floating-point formats differ but you have not used `FLOAT` or `DOUBLE` data types in your tables, then the procedure is the same: simply copy the relevant files. If the formats differ and your tables contain floating-point data, you must use `mysqldump` to dump your tables on one machine and then import the dump files on the other machine.

One way to increase performance is to switch off autocommit mode when importing data, assuming that the tablespace has enough space for the big rollback segment that the import transactions generate. Do the commit only after importing a whole table or a segment of a table.

14.5.10. InnoDB Transaction Model and Locking

In the InnoDB transaction model, the goal is to combine the best properties of a multi-versioning database with traditional two-phase locking. InnoDB does locking on the row level and runs queries as non-locking consistent reads by default, in the style of Oracle. The lock table in InnoDB is stored so space-efficiently that lock escalation is not needed: Typically several users are allowed to lock every row in the database, or any random subset of the rows, without InnoDB running out of memory.

14.5.10.1. InnoDB Lock Modes

InnoDB implements standard row-level locking where there are two types of locks:

- A shared (*S*) lock allows a transaction to read a row (tuple).
- An exclusive (*X*) lock allows a transaction to update or delete a row.

If transaction *T1* holds a shared (*S*) lock on tuple *t*, then

- A request from some distinct transaction *T2* for an *S* lock on *t* can be granted immediately. As a result, both *T1* and *T2* hold an *S* lock on *t*.
- A request from some distinct transaction *T2* for an *X* lock on *t* cannot be granted immediately.

If a transaction *T1* holds an exclusive (*X*) lock on tuple *t*, then a request from some distinct transaction *T2* for a lock of either type on *t* cannot be granted immediately. Instead, transaction *T2* has to wait for transaction *T1* to release its lock on tuple *t*.

Additionally, `InnoDB` supports *multiple granularity locking* which allows coexistence of record locks and locks on entire tables. To make locking at multiple granularity levels practical, additional types of locks called *intention locks* are used. Intention locks are table locks in `InnoDB`. The idea behind intention locks is for a transaction to indicate which type of lock (shared or exclusive) it will require later for a row in that table. There are two types of intention locks used in `InnoDB` (assume that transaction `T` has requested a lock of the indicated type on table `R`):

- Intention shared (`IS`): Transaction `T` intends to set `S` locks on individual rows in table `R`.
- Intention exclusive (`IX`): Transaction `T` intends to set `X` locks on those rows.

The intention locking protocol is as follows:

- Before a given transaction can acquire an `S` lock on a given row, it must first acquire an `IS` or stronger lock on the table containing that row.
- Before a given transaction can acquire an `X` lock on a given row, it must first acquire an `IX` lock on the table containing that row.

These rules can be conveniently summarized by means of a *lock type compatibility matrix*:

	<code>X</code>	<code>IX</code>	<code>S</code>	<code>IS</code>
<code>X</code>	Conflict	Conflict	Conflict	Conflict
<code>IX</code>	Conflict	Compatible	Conflict	Compatible
<code>S</code>	Conflict	Conflict	Compatible	Compatible
<code>IS</code>	Conflict	Compatible	Compatible	Compatible

A lock is granted to a requesting transaction if it is compatible with existing locks. A lock is not granted to a requesting transaction if it conflicts with existing locks. A transaction waits until the conflicting existing lock is released. If a lock request conflicts with an existing lock and cannot be granted because it would cause deadlock, an error occurs.

Thus, intention locks do not block anything except full table requests (for example, `LOCK TABLES ... WRITE`). The main purpose of `IX` and `IS` locks is to show that someone is locking a row, or going to lock a row in the table.

The following example illustrates how an error can occur when a lock request would cause a deadlock. The example involves two clients, A and B.

First, client A creates a table containing one row, and then begins a transaction. Within the transaction, A obtains an `S` lock on the row by selecting it in share mode:

```
mysql> CREATE TABLE t (i INT) ENGINE = InnoDB;
Query OK, 0 rows affected (1.07 sec)

mysql> INSERT INTO t (i) VALUES(1);
Query OK, 1 row affected (0.09 sec)

mysql> START TRANSACTION;
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT * FROM t WHERE i = 1 LOCK IN SHARE MODE;
+-----+
| i     |
+-----+
| 1    |
+-----+
```

```
+-----+
1 row in set (0.10 sec)
```

Next, client B begins a transaction and attempts to delete the row from the table:

```
mysql> START TRANSACTION;
Query OK, 0 rows affected (0.00 sec)

mysql> DELETE FROM t WHERE i = 1;
```

The delete operation requires an *X* lock. The lock cannot be granted because it is incompatible with the *S* lock that client A holds, so the request goes on the queue of lock requests for the row and client B blocks.

Finally, client A also attempts to delete the row from the table:

```
mysql> DELETE FROM t WHERE i = 1;
ERROR 1213 (40001): Deadlock found when trying to get lock;
try restarting transaction
```

Deadlock occurs here because client A needs an *X* lock to delete the row. However, that lock request cannot be granted because client B is already has a request for an *X* lock and is waiting for client A to release its *S* lock. Nor can the *S* lock held by A be upgraded to an *X* lock because of the prior request by B for an *X* lock. As a result, *InnoDB* generates an error for client A and releases its locks. At that point, the lock request for client B can be granted and B deletes the row from the table.

14.5.10.2. *InnoDB* and AUTOCOMMIT

In *InnoDB*, all user activity occurs inside a transaction. If the autocommit mode is enabled, each SQL statement forms a single transaction on its own. By default, MySQL starts new connections with autocommit enabled.

If the autocommit mode is switched off with `SET AUTOCOMMIT = 0`, then we can consider that a user always has a transaction open. An SQL `COMMIT` or `ROLLBACK` statement ends the current transaction and a new one starts. A `COMMIT` means that the changes made in the current transaction are made permanent and become visible to other users. A `ROLLBACK` statement, on the other hand, cancels all modifications made by the current transaction. Both statements release all *InnoDB* locks that were set during the current transaction.

If the connection has autocommit enabled, the user can still perform a multiple-statement transaction by starting it with an explicit `START TRANSACTION` or `BEGIN` statement and ending it with `COMMIT` or `ROLLBACK`.

14.5.10.3. *InnoDB* and TRANSACTION ISOLATION LEVEL

In terms of the SQL:1992 transaction isolation levels, the *InnoDB* default is `REPEATABLE READ`. *InnoDB* offers all four transaction isolation levels described by the SQL standard. You can set the default isolation level for all connections by using the `--transaction-isolation` option on the command line or in an option file. For example, you can set the option in the `[mysqld]` section of an option file like this:

```
[mysqld]
transaction-isolation = {READ-UNCOMMITTED | READ-COMMITTED
                        | REPEATABLE-READ | SERIALIZABLE}
```

A user can change the isolation level for a single session or for all new incoming connections with the `SET TRANSACTION` statement. Its syntax is as follows:

```
SET [SESSION | GLOBAL] TRANSACTION ISOLATION LEVEL
{READ UNCOMMITTED | READ COMMITTED
```

```
| REPEATABLE READ | SERIALIZABLE }
```

Note that there are hyphens in the level names for the `--transaction-isolation` option, but not for the `SET TRANSACTION` statement.

The default behavior is to set the isolation level for the next (not started) transaction. If you use the `GLOBAL` keyword, the statement sets the default transaction level globally for all new connections created from that point on (but not for existing connections). You need the `SUPER` privilege to do this. Using the `SESSION` keyword sets the default transaction level for all future transactions performed on the current connection.

Any client is free to change the session isolation level (even in the middle of a transaction), or the isolation level for the next transaction.

You can determine the global and session transaction isolation levels by checking the value of the `tx_isolation` system variable with these statements:

```
SELECT @@global.tx_isolation;
SELECT @@tx_isolation;
```

In row-level locking, `InnoDB` uses next-key locking. That means that besides index records, `InnoDB` can also lock the “gap” preceding an index record to block insertions by other users immediately before the index record. A next-key lock refers to a lock that locks an index record and the gap before it. A gap lock refers to a lock that only locks a gap before some index record.

A detailed description of each isolation level in `InnoDB` follows:

- `READ UNCOMMITTED`

`SELECT` statements are performed in a non-locking fashion, but a possible earlier version of a record might be used. Thus, using this isolation level, such reads are not consistent. This is also called a “dirty read.” Otherwise, this isolation level works like `READ COMMITTED`.

- `READ COMMITTED`

A somewhat Oracle-like isolation level. All `SELECT ... FOR UPDATE` and `SELECT ... LOCK IN SHARE MODE` statements lock only the index records, not the gaps before them, and thus allow the free insertion of new records next to locked records. `UPDATE` and `DELETE` statements using a unique index with a unique search condition lock only the index record found, not the gap before it. In range-type `UPDATE` and `DELETE` statements, `InnoDB` must set next-key or gap locks and block insertions by other users to the gaps covered by the range. This is necessary because “phantom rows” must be blocked for MySQL replication and recovery to work.

Consistent reads behave as in Oracle: Each consistent read, even within the same transaction, sets and reads its own fresh snapshot. See [Section 14.5.10.4, “Consistent Non-Locking Read”](#).

- `REPEATABLE READ`

This is the default isolation level of `InnoDB`. `SELECT ... FOR UPDATE`, `SELECT ... LOCK IN SHARE MODE`, `UPDATE`, and `DELETE` statements that use a unique index with a unique search condition lock only the index record found, not the gap before it. With other search conditions, these operations employ next-key locking, locking the index range scanned with next-key or gap locks, and block new insertions by other users.

In consistent reads, there is an important difference from the `READ COMMITTED` isolation level: All consistent reads within the same transaction read the same snapshot established by the first read. This convention means that if you issue several plain `SELECT` statements within the same transac-

tion, these `SELECT` statements are consistent also with respect to each other. See [Section 14.5.10.4, “Consistent Non-Locking Read”](#).

- `SERIALIZABLE`

This level is like `REPEATABLE READ`, but `InnoDB` implicitly commits all plain `SELECT` statements to `SELECT ... LOCK IN SHARE MODE`.

14.5.10.4. Consistent Non-Locking Read

A consistent read means that `InnoDB` uses multi-versioning to present to a query a snapshot of the database at a point in time. The query sees the changes made by those transactions that committed before that point of time, and no changes made by later or uncommitted transactions. The exception to this rule is that the query sees the changes made by earlier statements within the same transaction. Note that the exception to the rule causes the following anomaly: if you update some rows in a table, a `SELECT` will see the latest version of the updated rows, while it sees the old version of other rows. If other users simultaneously update the same table, the anomaly means that you may see the table in a state that never existed in the database.

If you are running with the default `REPEATABLE READ` isolation level, all consistent reads within the same transaction read the snapshot established by the first such read in that transaction. You can get a fresher snapshot for your queries by committing the current transaction and after that issuing new queries.

Consistent read is the default mode in which `InnoDB` processes `SELECT` statements in `READ COMMITTED` and `REPEATABLE READ` isolation levels. A consistent read does not set any locks on the tables it accesses, and therefore other users are free to modify those tables at the same time a consistent read is being performed on the table.

Note that consistent read does not work over `DROP TABLE` and over `ALTER TABLE`. Consistent read does not work over `DROP TABLE` because MySQL can't use a table that has been dropped and `InnoDB` destroys the table. Consistent read does not work over `ALTER TABLE` because `ALTER TABLE` works by making a temporary copy of the original table and deleting the original table when the temporary copy is built. When you reissue a consistent read within a transaction, rows in the new table are not visible because those rows did not exist when the transaction's snapshot was taken.

14.5.10.5. `SELECT ... FOR UPDATE` and `SELECT ... LOCK IN SHARE MODE` Locking Reads

In some circumstances, a consistent read is not convenient. For example, you might want to add a new row into your table `child`, and make sure that the child has a parent in table `parent`. The following example shows how to implement referential integrity in your application code.

Suppose that you use a consistent read to read the table `parent` and indeed see the parent of the child in the table. Can you safely add the child row to table `child`? No, because it may happen that meanwhile some other user deletes the parent row from the table `parent` without you being aware of it.

The solution is to perform the `SELECT` in a locking mode using `LOCK IN SHARE MODE`:

```
SELECT * FROM parent WHERE NAME = 'Jones' LOCK IN SHARE MODE;
```

Performing a read in share mode means that we read the latest available data, and set a shared mode lock on the rows we read. A shared mode lock prevents others from updating or deleting the row we have read. Also, if the latest data belongs to a yet uncommitted transaction of another client connection, we wait until that transaction commits. After we see that the preceding query returns the parent `'Jones'`, we can safely add the child record to the `child` table and commit our transaction.

Let us look at another example: We have an integer counter field in a table `child_codes` that we use to assign a unique identifier to each child added to table `child`. Obviously, using a consistent read or a shared mode read to read the present value of the counter is not a good idea because two users of the database may then see the same value for the counter, and a duplicate-key error occurs if two users attempt to add children with the same identifier to the table.

Here, `LOCK IN SHARE MODE` is not a good solution because if two users read the counter at the same time, at least one of them ends up in deadlock when attempting to update the counter.

In this case, there are two good ways to implement the reading and incrementing of the counter: (1) update the counter first by incrementing it by 1 and only after that read it, or (2) read the counter first with a lock mode `FOR UPDATE`, and increment after that. The latter approach can be implemented as follows:

```
SELECT counter_field FROM child_codes FOR UPDATE;
UPDATE child_codes SET counter_field = counter_field + 1;
```

A `SELECT ... FOR UPDATE` reads the latest available data, setting exclusive locks on each row it reads. Thus, it sets the same locks a searched SQL `UPDATE` would set on the rows.

The preceding description is merely an example of how `SELECT ... FOR UPDATE` works. In MySQL, the specific task of generating a unique identifier actually can be accomplished using only a single access to the table:

```
UPDATE child_codes SET counter_field = LAST_INSERT_ID(counter_field + 1);
SELECT LAST_INSERT_ID();
```

The `SELECT` statement merely retrieves the identifier information (specific to the current connection). It does not access any table.

Locks set by `IN SHARE MODE` and `FOR UPDATE` reads are released when the transaction is committed or rolled back.

14.5.10.6. Next-Key Locking: Avoiding the Phantom Problem

In row-level locking, `InnoDB` uses an algorithm called *next-key locking*. `InnoDB` performs the row-level locking in such a way that when it searches or scans an index of a table, it sets shared or exclusive locks on the index records it encounters. Thus, the row-level locks are actually index record locks.

The locks `InnoDB` sets on index records also affect the “gap” before that index record. If a user has a shared or exclusive lock on record `R` in an index, another user cannot insert a new index record immediately before `R` in the index order. This locking of gaps is done to prevent the so-called “phantom problem.” Suppose that you want to read and lock all children from the `child` table having an identifier value greater than 100, with the intention of updating some column in the selected rows later:

```
SELECT * FROM child WHERE id > 100 FOR UPDATE;
```

Suppose that there is an index on the `id` column. The query scans that index starting from the first record where `id` is bigger than 100. If the locks set on the index records would not lock out inserts made in the gaps, a new row might meanwhile be inserted to the table. If you execute the same `SELECT` within the same transaction, you would see a new row in the result set returned by the query. This is contrary to the isolation principle of transactions: A transaction should be able to run so that the data it has read does not change during the transaction. If we regard a set of rows as a data item, the new “phantom” child would violate this isolation principle.

When `InnoDB` scans an index, it can also lock the gap after the last record in the index. Just that happens in the previous example: The locks set by `InnoDB` prevent any insert to the table where `id` would

be bigger than 100.

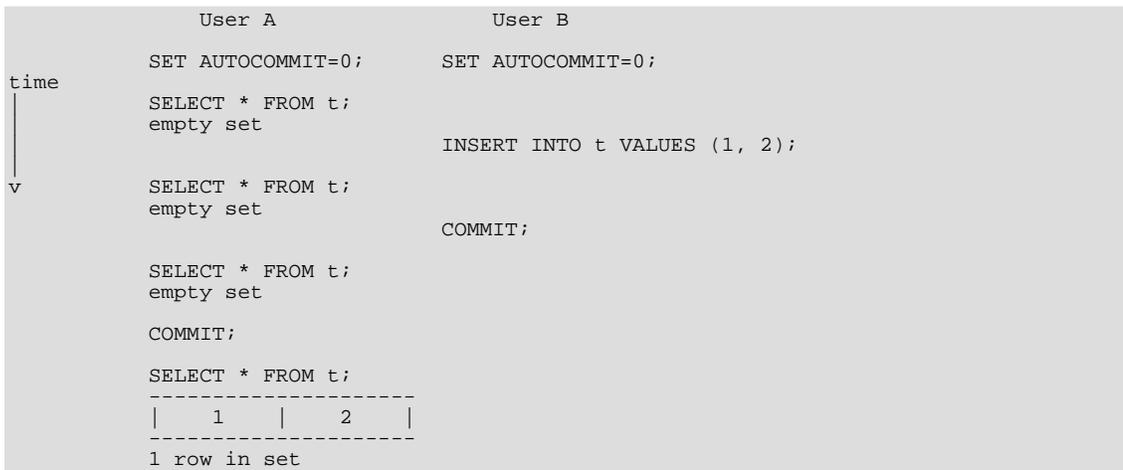

You can use next-key locking to implement a uniqueness check in your application: If you read your data in share mode and do not see a duplicate for a row you are going to insert, then you can safely insert your row and know that the next-key lock set on the successor of your row during the read prevents anyone meanwhile inserting a duplicate for your row. Thus, the next-key locking allows you to “lock” the non-existence of something in your table.

14.5.10.7. An Example of Consistent Read in InnoDB

Suppose that you are running in the default `REPEATABLE READ` isolation level. When you issue a consistent read (that is, an ordinary `SELECT` statement), InnoDB gives your transaction a timepoint according to which your query sees the database. If another transaction deletes a row and commits after your timepoint was assigned, you do not see the row as having been deleted. Inserts and updates are treated similarly.

You can advance your timepoint by committing your transaction and then doing another `SELECT`.

This is called *multi-versioned concurrency control*.

In this example, user A sees the row inserted by B only when B has committed the insert and A has committed as well, so that the timepoint is advanced past the commit of B.

If you want to see the “freshest” state of the database, you should use either the `READ COMMITTED` isolation level or a locking read:

```
SELECT * FROM t LOCK IN SHARE MODE;
```

14.5.10.8. Locks Set by Different SQL Statements in InnoDB

A locking read, an `UPDATE`, or a `DELETE` generally set record locks on every index record that is scanned in the processing of the SQL statement. It does not matter if there are `WHERE` conditions in the statement that would exclude the row. InnoDB does not remember the exact `WHERE` condition, but only knows which index ranges were scanned. The record locks are normally next-key locks that also block inserts to the “gap” immediately before the record.

If the locks to be set are exclusive, InnoDB always retrieves also the clustered index record and sets a lock on it.

If you do not have indexes suitable for your statement and MySQL has to scan the whole table to process the statement, every row of the table becomes locked, which in turn blocks all inserts by other users

to the table. It is important to create good indexes so that your queries do not unnecessarily need to scan many rows.

InnoDB sets specific types of locks as follows:

- `SELECT ... FROM` is a consistent read, reading a snapshot of the database and setting no locks unless the transaction isolation level is set to `SERIALIZABLE`. For `SERIALIZABLE` level, this sets shared next-key locks on the index records it encounters.
- `SELECT ... FROM ... LOCK IN SHARE MODE` sets shared next-key locks on all index records the read encounters.
- `SELECT ... FROM ... FOR UPDATE` sets exclusive next-key locks on all index records the read encounters.
- `INSERT INTO ... VALUES (...)` sets an exclusive lock on the inserted row. Note that this lock is not a next-key lock and does not prevent other users from inserting to the gap before the inserted row. If a duplicate-key error occurs, a shared lock on the duplicate index record is set.
- While initializing a previously specified `AUTO_INCREMENT` column on a table, InnoDB sets an exclusive lock on the end of the index associated with the `AUTO_INCREMENT` column. In accessing the auto-increment counter, InnoDB uses a specific table lock mode `AUTO-INC` where the lock lasts only to the end of the current SQL statement, not to the end of the entire transaction. Note that other clients cannot insert into the table while the `AUTO-INC` table lock is held; see [Section 14.5.10.2, “InnoDB and AUTOCOMMIT”](#).

InnoDB fetches the value of a previously initialized `AUTO_INCREMENT` column without setting any locks.

- `INSERT INTO T SELECT ... FROM S WHERE ...` sets an exclusive (non-next-key) lock on each row inserted into T. InnoDB sets shared next-key locks on S, unless `innodb_locks_unsafe_for_binlog` is enabled, in which case it does the search on S as a consistent read. InnoDB has to set locks in the latter case: In roll-forward recovery from a backup, every SQL statement has to be executed in exactly the same way it was done originally.
- `CREATE TABLE ... SELECT ...` performs the `SELECT` as a consistent read or with shared locks, as in the previous item.
- `REPLACE` is done like an insert if there is no collision on a unique key. Otherwise, an exclusive next-key lock is placed on the row that has to be updated.
- `UPDATE ... WHERE ...` sets an exclusive next-key lock on every record the search encounters.
- `DELETE FROM ... WHERE ...` sets an exclusive next-key lock on every record the search encounters.
- If a `FOREIGN KEY` constraint is defined on a table, any insert, update, or delete that requires the constraint condition to be checked sets shared record-level locks on the records that it looks at to check the constraint. InnoDB also sets these locks in the case where the constraint fails.
- `LOCK TABLES` sets table locks, but it is the higher MySQL layer above the InnoDB layer that sets these locks. InnoDB is aware of table locks if `innodb_table_locks=1` (the default) and `AUTOCOMMIT=0`, and the MySQL layer above InnoDB knows about row-level locks. Otherwise, InnoDB's automatic deadlock detection cannot detect deadlocks where such table locks are involved. Also, because the higher MySQL layer does not know about row-level locks, it is possible to get a table lock on a table where another user currently has row-level locks. However, this does not endanger transaction integrity, as discussed in [Section 14.5.10.10, “Deadlock Detection and Roll-back”](#). See also [Section 14.5.16, “Restrictions on InnoDB Tables”](#).

14.5.10.9. Implicit Transaction Commit and Rollback

By default, MySQL begins each client connection with autocommit mode enabled. When autocommit is enabled, MySQL does a commit after each SQL statement if that statement did not return an error. If an SQL statement returns an error, the commit or rollback behavior depends on the error. See [Section 14.5.15, “InnoDB Error Handling”](#).

If you have the autocommit mode off and close a connection without explicitly committing the final transaction, MySQL rolls back that transaction.

Each of the following statements (and any synonyms for them) implicitly end a transaction, as if you had done a `COMMIT` before executing the statement:

- `ALTER FUNCTION`, `ALTER PROCEDURE`, `ALTER TABLE`, `BEGIN`, `CREATE DATABASE`, `CREATE FUNCTION`, `CREATE INDEX`, `CREATE PROCEDURE`, `CREATE TABLE`, `DROP DATABASE`, `DROP FUNCTION`, `DROP INDEX`, `DROP PROCEDURE`, `DROP TABLE`, `LOAD MASTER DATA`, `LOCK TABLES`, `RENAME TABLE`, `SET AUTOCOMMIT=1`, `START TRANSACTION`, `TRUNCATE`, `UNLOCK TABLES`.
- `UNLOCK TABLES` commits a transaction only if any tables are currently locked.
- The `CREATE TABLE` statement in InnoDB is processed as a single transaction. This means that a `ROLLBACK` from the user does not undo `CREATE TABLE` statements the user made during that transaction.
- Prior to MySQL 5.1.12, `LOAD DATA INFILE` also caused an implicit commit for InnoDB tables (as was true for all storage engines).

Transactions cannot be nested. This is a consequence of the implicit `COMMIT` performed for any current transaction when you issue a `START TRANSACTION` statement or one of its synonyms.

Statements that cause implicit cannot be used in an XA transaction while the transaction is in an `ACTIVE` state.

14.5.10.10. Deadlock Detection and Rollback

InnoDB automatically detects a deadlock of transactions and rolls back a transaction or transactions to break the deadlock. InnoDB tries to pick small transactions to roll back, where the size of a transaction is determined by the number of rows inserted, updated, or deleted.

InnoDB is aware of table locks if `innodb_table_locks=1` (the default) and `AUTOCOMMIT=0`, and the MySQL layer above it knows about row-level locks. Otherwise, InnoDB cannot detect deadlocks where a table lock set by a MySQL `LOCK TABLES` statement or a lock set by a storage engine other than InnoDB is involved. You must resolve these situations by setting the value of the `innodb_lock_wait_timeout` system variable.

When InnoDB performs a complete rollback of a transaction, all locks set by the transaction are released. However, if just a single SQL statement is rolled back as a result of an error, some of the locks set by the statement may be preserved. This happens because InnoDB stores row locks in a format such that it cannot know afterward which lock was set by which statement.

14.5.10.11. How to Cope with Deadlocks

Deadlocks are a classic problem in transactional databases, but they are not dangerous unless they are so frequent that you cannot run certain transactions at all. Normally, you must write your applications so that they are always prepared to re-issue a transaction if it gets rolled back because of a deadlock.

InnoDB uses automatic row-level locking. You can get deadlocks even in the case of transactions that just insert or delete a single row. That is because these operations are not really “atomic”; they automatically set locks on the (possibly several) index records of the row inserted or deleted.

You can cope with deadlocks and reduce the likelihood of their occurrence with the following techniques:

- Use `SHOW ENGINE INNODB STATUS` to determine the cause of the latest deadlock. That can help you to tune your application to avoid deadlocks.
- Always be prepared to re-issue a transaction if it fails due to deadlock. Deadlocks are not dangerous. Just try again.
- Commit your transactions often. Small transactions are less prone to collision.
- If you are using locking reads (`SELECT ... FOR UPDATE` or `... LOCK IN SHARE MODE`), try using a lower isolation level such as `READ COMMITTED`.
- Access your tables and rows in a fixed order. Then transactions form well-defined queues and do not deadlock.
- Add well-chosen indexes to your tables. Then your queries need to scan fewer index records and consequently set fewer locks. Use `EXPLAIN SELECT` to determine which indexes the MySQL server regards as the most appropriate for your queries.
- Use less locking. If you can afford to allow a `SELECT` to return data from an old snapshot, do not add the clause `FOR UPDATE` or `LOCK IN SHARE MODE` to it. Using the `READ COMMITTED` isolation level is good here, because each consistent read within the same transaction reads from its own fresh snapshot.
- If nothing else helps, serialize your transactions with table-level locks. The correct way to use `LOCK TABLES` with transactional tables, such as **InnoDB** tables, is to set `AUTOCOMMIT = 0` and not to call `UNLOCK TABLES` until after you commit the transaction explicitly. For example, if you need to write to table `t1` and read from table `t2`, you can do this:

```
SET AUTOCOMMIT=0;
LOCK TABLES t1 WRITE, t2 READ, ...;
... do something with tables t1 and t2 here ...
COMMIT;
UNLOCK TABLES;
```

Table-level locks make your transactions queue nicely, and deadlocks are avoided.

- Another way to serialize transactions is to create an auxiliary “semaphore” table that contains just a single row. Have each transaction update that row before accessing other tables. In that way, all transactions happen in a serial fashion. Note that the **InnoDB** instant deadlock detection algorithm also works in this case, because the serializing lock is a row-level lock. With MySQL table-level locks, the timeout method must be used to resolve deadlocks.
- In applications that use the `LOCK TABLES` command, MySQL does not set **InnoDB** table locks if `AUTOCOMMIT=1`.

14.5.11. **InnoDB** Performance Tuning Tips

- In **InnoDB**, having a long `PRIMARY KEY` wastes a lot of disk space because its value must be stored with every secondary index record. (See [Section 14.5.13](#), “**InnoDB** Table and Index Struc-

tures”). Create an `AUTO_INCREMENT` column as the primary key if your primary key is long.

- If the Unix `top` tool or the Windows Task Manager shows that the CPU usage percentage with your workload is less than 70%, your workload is probably disk-bound. Maybe you are making too many transaction commits, or the buffer pool is too small. Making the buffer pool bigger can help, but do not set it equal to more than 80% of physical memory.
- Wrap several modifications into one transaction. `InnoDB` must flush the log to disk at each transaction commit if that transaction made modifications to the database. The rotation speed of a disk is typically at most 167 revolutions/second, which constrains the number of commits to the same 167th of a second if the disk does not “fool” the operating system.
- If you can afford the loss of some of the latest committed transactions if a crash occurs, you can set the `innodb_flush_log_at_trx_commit` parameter to 0. `InnoDB` tries to flush the log once per second anyway, although the flush is not guaranteed.
- Make your log files big, even as big as the buffer pool. When `InnoDB` has written the log files full, it has to write the modified contents of the buffer pool to disk in a checkpoint. Small log files cause many unnecessary disk writes. The drawback of big log files is that the recovery time is longer.
- Make the log buffer quite large as well (on the order of 8MB).
- Use the `VARCHAR` data type instead of `CHAR` if you are storing variable-length strings or if the column may contain many `NULL` values. A `CHAR(N)` column always takes `N` characters to store data, even if the string is shorter or its value is `NULL`. Smaller tables fit better in the buffer pool and reduce disk I/O.

When using `row_format=compact` (the default `InnoDB` record format in MySQL 5.1) and variable-length character sets, such as `utf8` or `sjis`, `CHAR(N)` will occupy a variable amount of space, at least `N` bytes.

- In some versions of GNU/Linux and Unix, flushing files to disk with the Unix `fsync()` call (which `InnoDB` uses by default) and other similar methods is surprisingly slow. If you are dissatisfied with database write performance, you might try setting the `innodb_flush_method` parameter to `O_DSYNC`. Although `O_DSYNC` seems to be slower on most systems, yours might not be one of them.
- When using the `InnoDB` storage engine on Solaris 10 for x86_64 architecture (AMD Opteron), it is important to mount any filesystems used for storing `InnoDB`-related files using the `forcedirectio` option. (The default on Solaris 10/x86_64 is *not* to use this option.) Failure to use `forcedirectio` causes a serious degradation of `InnoDB`'s speed and performance on this platform.

When using the `InnoDB` storage engine with a large `innodb_buffer_pool_size` value on any release of Solaris 2.6 and up and any platform (sparc/x86/x64/amd64), a significant performance gain can be achieved by placing `InnoDB` data files and log files on raw devices or on a separate direct I/O UFS filesystem (using mount option `forcedirectio`; see `mount_ufs(1M)`). Users of the Veritas filesystem VxFS should use the mount option `convosync=direct`.

Other MySQL data files, such as those for `MyISAM` tables, should not be placed on a direct I/O filesystem. Executables or libraries *must not* be placed on a direct I/O filesystem.

- When importing data into `InnoDB`, make sure that MySQL does not have autocommit mode enabled because that requires a log flush to disk for every insert. To disable autocommit during your import operation, surround it with `SET AUTOCOMMIT` and `COMMIT` statements:

```
SET AUTOCOMMIT=0;
... SQL import statements ...
COMMIT;
```

If you use the `mysqldump` option `--opt`, you get dump files that are fast to import into an `InnoDB` table, even without wrapping them with the `SET AUTOCOMMIT` and `COMMIT` statements.

- Beware of big rollbacks of mass inserts: `InnoDB` uses the insert buffer to save disk I/O in inserts, but no such mechanism is used in a corresponding rollback. A disk-bound rollback can take 30 times as long to perform as the corresponding insert. Killing the database process does not help because the rollback starts again on server startup. The only way to get rid of a runaway rollback is to increase the buffer pool so that the rollback becomes CPU-bound and runs fast, or to use a special procedure. See [Section 14.5.8.1, “Forcing InnoDB Recovery”](#).
- Beware also of other big disk-bound operations. Use `DROP TABLE` and `CREATE TABLE` to empty a table, not `DELETE FROM tbl_name`.
- Use the multiple-row `INSERT` syntax to reduce communication overhead between the client and the server if you need to insert many rows:

```
INSERT INTO yourtable VALUES (1,2), (5,5), ...;
```

This tip is valid for inserts into any table, not just `InnoDB` tables.

- If you have `UNIQUE` constraints on secondary keys, you can speed up table imports by temporarily turning off the uniqueness checks during the import session:

```
SET UNIQUE_CHECKS=0;
... import operation ...
SET UNIQUE_CHECKS=1;
```

For big tables, this saves a lot of disk I/O because `InnoDB` can use its insert buffer to write secondary index records in a batch. Be certain that the data contains no duplicate keys. `UNIQUE_CHECKS` allows but does not require storage engines to ignore duplicate keys.

- If you have `FOREIGN KEY` constraints in your tables, you can speed up table imports by turning the foreign key checks off for the duration of the import session:

```
SET FOREIGN_KEY_CHECKS=0;
... import operation ...
SET FOREIGN_KEY_CHECKS=1;
```

For big tables, this can save a lot of disk I/O.

- If you often have recurring queries for tables that are not updated frequently, use the query cache:

```
[mysqld]
query_cache_type = ON
query_cache_size = 10M
```

- Unlike `MyISAM`, `InnoDB` does not store an index cardinality value in its tables. Instead, `InnoDB` computes a cardinality for a table the first time it accesses it after startup. With a large number of tables, this might take significant time. It is the initial table open operation that is important, so to “warm up” a table for later use, you might want to use it immediately after start up by issuing a statement such as `SELECT 1 FROM tbl_name LIMIT 1`.

14.5.11.1. `SHOW ENGINE INNODB STATUS` and the `InnoDB` Monitors

`InnoDB` includes `InnoDB` Monitors that print information about the `InnoDB` internal state. You can use the `SHOW ENGINE INNODB STATUS` SQL statement at any time to fetch the output of the standard `InnoDB` Monitor to your SQL client. This information is useful in performance tuning. (If you are

using the `mysql` interactive SQL client, the output is more readable if you replace the usual semicolon statement terminator with `\G`.) For a discussion of `InnoDB` lock modes, see [Section 14.5.10.1, “InnoDB Lock Modes”](#).

```
mysql> SHOW ENGINE INNODB STATUS\G
```

Another way to use `InnoDB` Monitors is to let them periodically write data to the standard output of the `mysqld` server. In this case, no output is sent to clients. When switched on, `InnoDB` Monitors print data about every 15 seconds. Server output usually is directed to the `.err` log in the MySQL data directory. This data is useful in performance tuning. On Windows, you must start the server from a command prompt in a console window with the `--console` option if you want to direct the output to the window rather than to the error log.

Monitor output includes the following types of information:

- Table and record locks held by each active transaction
- Lock waits of a transactions
- Semaphore waits of threads
- Pending file I/O requests
- Buffer pool statistics
- Purge and insert buffer merge activity of the main `InnoDB` thread

To cause the standard `InnoDB` Monitor to write to the standard output of `mysqld`, use the following SQL statement:

```
CREATE TABLE innodb_monitor (a INT) ENGINE=INNODB;
```

The monitor can be stopped by issuing the following statement:

```
DROP TABLE innodb_monitor;
```

The `CREATE TABLE` syntax is just a way to pass a command to the `InnoDB` engine through MySQL's SQL parser: The only things that matter are the table name `innodb_monitor` and that it be an `InnoDB` table. The structure of the table is not relevant at all for the `InnoDB` Monitor. If you shut down the server, the monitor does not restart automatically when you restart the server. You must drop the monitor table and issue a new `CREATE TABLE` statement to start the monitor. (This syntax may change in a future release.)

You can use `innodb_lock_monitor` in a similar fashion. This is the same as `innodb_monitor`, except that it also provides a great deal of lock information. A separate `innodb_tablespace_monitor` prints a list of created file segments existing in the tablespace and validates the tablespace allocation data structures. In addition, there is `innodb_table_monitor` with which you can print the contents of the `InnoDB` internal data dictionary.

A sample of `InnoDB` Monitor output:

```
mysql> SHOW ENGINE INNODB STATUS\G
***** 1. row *****
Status:

END OF INNODB MONITOR OUTPUT
=====

```

Some notes on the output:

- If the [TRANSACTIONS](#) section reports lock waits, your applications may have lock contention. The output can also help to trace the reasons for transaction deadlocks.
- The [SEMAPHORES](#) section reports threads waiting for a semaphore and statistics on how many times threads have needed a spin or a wait on a mutex or a rw-lock semaphore. A large number of threads waiting for semaphores may be a result of disk I/O, or contention problems inside [InnoDB](#). Contention can be due to heavy parallelism of queries or problems in operating system thread scheduling. Setting [innodb_thread_concurrency](#) smaller than the default value can help in such situations.
- The [BUFFER POOL AND MEMORY](#) section gives you statistics on pages read and written. You can calculate from these numbers how many data file I/O operations your queries currently are doing.
- The [ROW OPERATIONS](#) section shows what the main thread is doing.

[InnoDB](#) sends diagnostic output to `stderr` or to files rather than to `stdout` or fixed-size memory buffers, to avoid potential buffer overflows. As a side effect, the output of [SHOW ENGINE INNODB STATUS](#) is written to a status file in the MySQL data directory every fifteen seconds. The name of the file is `innodb_status.pid`, where `pid` is the server process ID. [InnoDB](#) removes the file for a normal shutdown. If abnormal shutdowns have occurred, instances of these status files may be present and must be removed manually. Before removing them, you might want to examine them to see whether they contain useful information about the cause of abnormal shutdowns. The `innodb_status.pid` file is created only if the configuration option `innodb_status_file=1` is set.

14.5.12. Implementation of Multi-Versioning

Because [InnoDB](#) is a multi-versioned storage engine, it must keep information about old versions of rows in the tablespace. This information is stored in a data structure called a *rollback segment* (after an analogous data structure in Oracle).

Internally, [InnoDB](#) adds two fields to each row stored in the database. A 6-byte field indicates the transaction identifier for the last transaction that inserted or updated the row. Also, a deletion is treated internally as an update where a special bit in the row is set to mark it as deleted. Each row also contains a 7-byte field called the roll pointer. The roll pointer points to an undo log record written to the rollback segment. If the row was updated, the undo log record contains the information necessary to rebuild the content of the row before it was updated.

[InnoDB](#) uses the information in the rollback segment to perform the undo operations needed in a transaction rollback. It also uses the information to build earlier versions of a row for a consistent read.

Undo logs in the rollback segment are divided into insert and update undo logs. Insert undo logs are needed only in transaction rollback and can be discarded as soon as the transaction commits. Update undo logs are used also in consistent reads, but they can be discarded only after there is no transaction present for which [InnoDB](#) has assigned a snapshot that in a consistent read could need the information in the update undo log to build an earlier version of a database row.

You must remember to commit your transactions regularly, including those transactions that issue only consistent reads. Otherwise, `InnoDB` cannot discard data from the update undo logs, and the rollback segment may grow too big, filling up your tablespace.

The physical size of an undo log record in the rollback segment is typically smaller than the corresponding inserted or updated row. You can use this information to calculate the space need for your rollback segment.

In the `InnoDB` multi-versioning scheme, a row is not physically removed from the database immediately when you delete it with an SQL statement. Only when `InnoDB` can discard the update undo log record written for the deletion can it also physically remove the corresponding row and its index records from the database. This removal operation is called a purge, and it is quite fast, usually taking the same order of time as the SQL statement that did the deletion.

In a scenario where the user inserts and deletes rows in smallish batches at about the same rate in the table, it is possible that the purge thread starts to lag behind, and the table grows bigger and bigger, making everything disk-bound and very slow. Even if the table carries just 10MB of useful data, it may grow to occupy 10GB with all the “dead” rows. In such a case, it would be good to throttle new row operations, and allocate more resources to the purge thread. The `innodb_max_purge_lag` system variable exists for exactly this purpose. See [Section 14.5.4, “InnoDB Startup Options and System Variables”](#), for more information.

14.5.13. InnoDB Table and Index Structures

MySQL stores its data dictionary information for tables in `.frm` files in database directories. This is true for all MySQL storage engines. But every `InnoDB` table also has its own entry in the `InnoDB` internal data dictionary inside the tablespace. When MySQL drops a table or a database, it has to delete both an `.frm` file or files, and the corresponding entries inside the `InnoDB` data dictionary. This is the reason why you cannot move `InnoDB` tables between databases simply by moving the `.frm` files.

Every `InnoDB` table has a special index called the *clustered index* where the data for the rows is stored. If you define a `PRIMARY KEY` on your table, the index of the primary key is the clustered index.

If you do not define a `PRIMARY KEY` for your table, MySQL picks the first `UNIQUE` index that has only `NOT NULL` columns as the primary key and `InnoDB` uses it as the clustered index. If there is no such index in the table, `InnoDB` internally generates a clustered index where the rows are ordered by the row ID that `InnoDB` assigns to the rows in such a table. The row ID is a 6-byte field that increases monotonically as new rows are inserted. Thus, the rows ordered by the row ID are physically in insertion order.

Accessing a row through the clustered index is fast because the row data is on the same page where the index search leads. If a table is large, the clustered index architecture often saves a disk I/O when compared to the traditional solution. (In many database systems, data storage uses a different page from the index record.)

In `InnoDB`, the records in non-clustered indexes (also called secondary indexes) contain the primary key value for the row. `InnoDB` uses this primary key value to search for the row from the clustered index. Note that if the primary key is long, the secondary indexes use more space.

`InnoDB` compares `CHAR` and `VARCHAR` strings of different lengths such that the remaining length in the shorter string is treated as if padded with spaces.

14.5.13.1. Physical Structure of an Index

All `InnoDB` indexes are B-trees where the index records are stored in the leaf pages of the tree. The default size of an index page is 16KB. When new records are inserted, `InnoDB` tries to leave 1/16 of the page free for future insertions and updates of the index records.

If index records are inserted in a sequential order (ascending or descending), the resulting index pages are about 15/16 full. If records are inserted in a random order, the pages are from 1/2 to 15/16 full. If the fill factor of an index page drops below 1/2, [InnoDB](#) tries to contract the index tree to free the page.

14.5.13.2. Insert Buffering

It is a common situation in database applications that the primary key is a unique identifier and new rows are inserted in the ascending order of the primary key. Thus, the insertions to the clustered index do not require random reads from a disk.

On the other hand, secondary indexes are usually non-unique, and insertions into secondary indexes happen in a relatively random order. This would cause a lot of random disk I/O operations without a special mechanism used in [InnoDB](#).

If an index record should be inserted to a non-unique secondary index, [InnoDB](#) checks whether the secondary index page is in the buffer pool. If that is the case, [InnoDB](#) does the insertion directly to the index page. If the index page is not found in the buffer pool, [InnoDB](#) inserts the record to a special insert buffer structure. The insert buffer is kept so small that it fits entirely in the buffer pool, and insertions can be done very fast.

Periodically, the insert buffer is merged into the secondary index trees in the database. Often it is possible to merge several insertions to the same page of the index tree, saving disk I/O operations. It has been measured that the insert buffer can speed up insertions into a table up to 15 times.

The insert buffer merging may continue to happen *after* the inserting transaction has been committed. In fact, it may continue to happen after a server shutdown and restart (see [Section 14.5.8.1, “Forcing InnoDB Recovery”](#)).

The insert buffer merging may take many hours, when many secondary indexes must be updated, and many rows have been inserted. During this time, disk I/O will be increased, which can cause significant slowdown on disk-bound queries. Another significant background I/O operation is the purge thread (see [Section 14.5.12, “Implementation of Multi-Versioning”](#)).

14.5.13.3. Adaptive Hash Indexes

If a table fits almost entirely in main memory, the fastest way to perform queries on it is to use hash indexes. [InnoDB](#) has a mechanism that monitors index searches made to the indexes defined for a table. If [InnoDB](#) notices that queries could benefit from building a hash index, it does so automatically.

Note that the hash index is always built based on an existing B-tree index on the table. [InnoDB](#) can build a hash index on a prefix of any length of the key defined for the B-tree, depending on the pattern of searches that [InnoDB](#) observes for the B-tree index. A hash index can be partial: It is not required that the whole B-tree index is cached in the buffer pool. [InnoDB](#) builds hash indexes on demand for those pages of the index that are often accessed.

In a sense, [InnoDB](#) tailors itself through the adaptive hash index mechanism to ample main memory, coming closer to the architecture of main-memory databases.

14.5.13.4. Physical Row Structure

The physical record structure for [InnoDB](#) tables is dependent on the row format specified when the table was created. For MySQL 5.1, by default [InnoDB](#) uses the [COMPACT](#) format, but the [REDUNDANT](#) format is available to retain compatibility with older versions of MySQL.

Records in [InnoDB](#) [ROW_FORMAT=REDUNDANT](#) tables have the following characteristics:

- Each index record contains a six-byte header. The header is used to link together consecutive re-

cords, and also in row-level locking.

- Records in the clustered index contain fields for all user-defined columns. In addition, there is a six-byte field for the transaction ID and a seven-byte field for the roll pointer.
- If no primary key was defined for a table, each clustered index record also contains a six-byte row ID field.
- Each secondary index record contains also all the fields defined for the clustered index key.
- A record contains also a pointer to each field of the record. If the total length of the fields in a record is less than 128 bytes, the pointer is one byte; otherwise, two bytes. The array of these pointers is called the record directory. The area where these pointers point is called the data part of the record.
- Internally, InnoDB stores fixed-length character columns such as `CHAR(10)` in a fixed-length format. InnoDB truncates trailing spaces from `VARCHAR` columns.
- An SQL `NULL` value reserves 1 or 2 bytes in the record directory. Besides that, an SQL `NULL` value reserves zero bytes in the data part of the record if stored in a variable length column. In a fixed-length column, it reserves the fixed length of the column in the data part of the record. The motivation behind reserving the fixed space for `NULL` values is that it enables an update of the column from `NULL` to a non-`NULL` value to be done in place without causing fragmentation of the index page.

Records in InnoDB `ROW_FORMAT=COMPACT` tables have the following characteristics:

- Each index record contains a five-byte header that may be preceded by a variable-length header. The header is used to link together consecutive records, and also in row-level locking.
- The record header contains a bit vector for indicating `NULL` columns. The bit vector occupies $(n_nullable+7)/8$ bytes. Columns that are `NULL` will not occupy other space than the bit in this vector.
- For each non-`NULL` variable-length field, the record header contains the length of the column in one or two bytes. Two bytes will only be needed if part of the column is stored externally or the maximum length exceeds 255 bytes and the actual length exceeds 127 bytes.
- The record header is followed by the data contents of the columns. Columns that are `NULL` are omitted.
- Records in the clustered index contain fields for all user-defined columns. In addition, there is a six-byte field for the transaction ID and a seven-byte field for the roll pointer.
- If no primary key was defined for a table, each clustered index record also contains a six-byte row ID field.
- Each secondary index record contains also all the fields defined for the clustered index key.
- Internally, InnoDB stores fixed-length, fixed-width character columns such as `CHAR(10)` in a fixed-length format. InnoDB truncates trailing spaces from `VARCHAR` columns.
- Internally, InnoDB attempts to store UTF-8 `CHAR(n)` columns in `n` bytes by trimming trailing spaces. In `ROW_FORMAT=REDUNDANT`, such columns occupy $3*n$ bytes. The motivation behind reserving the minimum space `n` is that it in many cases enables an update of the column to be done in place without causing fragmentation of the index page.

14.5.14. InnoDB File Space Management and Disk I/O

14.5.14.1. InnoDB Disk I/O

InnoDB uses simulated asynchronous disk I/O: InnoDB creates a number of threads to take care of I/O operations, such as read-ahead.

There are two read-ahead heuristics in InnoDB:

- In sequential read-ahead, if InnoDB notices that the access pattern to a segment in the tablespace is sequential, it posts in advance a batch of reads of database pages to the I/O system.
- In random read-ahead, if InnoDB notices that some area in a tablespace seems to be in the process of being fully read into the buffer pool, it posts the remaining reads to the I/O system.

InnoDB uses a novel file flush technique called *doublewrite*. It adds safety to recovery following an operating system crash or a power outage, and improves performance on most varieties of Unix by reducing the need for `fsync()` operations.

Doublewrite means that before writing pages to a data file, InnoDB first writes them to a contiguous tablespace area called the doublewrite buffer. Only after the write and the flush to the doublewrite buffer has completed does InnoDB write the pages to their proper positions in the data file. If the operating system crashes in the middle of a page write, InnoDB can later find a good copy of the page from the doublewrite buffer during recovery.

14.5.14.2. File Space Management

The data files that you define in the configuration file form the tablespace of InnoDB. The files are simply concatenated to form the tablespace. There is no striping in use. Currently, you cannot define where within the tablespace your tables are allocated. However, in a newly created tablespace, InnoDB allocates space starting from the first data file.

The tablespace consists of database pages with a default size of 16KB. The pages are grouped into extents of 64 consecutive pages. The “files” inside a tablespace are called *segments* in InnoDB. The term “rollback segment” is somewhat confusing because it actually contains many tablespace segments.

Two segments are allocated for each index in InnoDB. One is for non-leaf nodes of the B-tree, the other is for the leaf nodes. The idea here is to achieve better sequentiality for the leaf nodes, which contain the data.

When a segment grows inside the tablespace, InnoDB allocates the first 32 pages to it individually. After that InnoDB starts to allocate whole extents to the segment. InnoDB can add to a large segment up to 4 extents at a time to ensure good sequentiality of data.

Some pages in the tablespace contain bitmaps of other pages, and therefore a few extents in an InnoDB tablespace cannot be allocated to segments as a whole, but only as individual pages.

When you ask for available free space in the tablespace by issuing a `SHOW TABLE STATUS` statement, InnoDB reports the extents that are definitely free in the tablespace. InnoDB always reserves some extents for cleanup and other internal purposes; these reserved extents are not included in the free space.

When you delete data from a table, InnoDB contracts the corresponding B-tree indexes. Whether the freed space becomes available for other users depends on whether the pattern of deletes frees individual pages or extents to the tablespace. Dropping a table or deleting all rows from it is guaranteed to release the space to other users, but remember that deleted rows are physically removed only in an (automatic) purge operation after they are no longer needed for transaction rollbacks or consistent reads. (See [Section 14.5.12, “Implementation of Multi-Versioning”](#).)

14.5.14.3. Defragmenting a Table

If there are random insertions into or deletions from the indexes of a table, the indexes may become fragmented. Fragmentation means that the physical ordering of the index pages on the disk is not close to the index ordering of the records on the pages, or that there are many unused pages in the 64-page blocks that were allocated to the index.

A symptom of fragmentation is that a table takes more space than it “should” take. How much that is exactly, is difficult to determine. All **InnoDB** data and indexes are stored in B-trees, and their fill factor may vary from 50% to 100%. Another symptom of fragmentation is that a table scan such as this takes more time than it “should” take:

```
SELECT COUNT(*) FROM t WHERE a_non_indexed_column <> 12345;
```

(In the preceding query, we are “fooling” the SQL optimizer into scanning the clustered index, rather than a secondary index.) Most disks can read 10 to 50MB/s, which can be used to estimate how fast a table scan should run.

It can speed up index scans if you periodically perform a “null” **ALTER TABLE** operation:

```
ALTER TABLE tbl_name ENGINE=INNODB
```

That causes MySQL to rebuild the table. Another way to perform a defragmentation operation is to use **mysqldump** to dump the table to a text file, drop the table, and reload it from the dump file.

If the insertions to an index are always ascending and records are deleted only from the end, the **InnoDB** filespace management algorithm guarantees that fragmentation in the index does not occur.

14.5.15. InnoDB Error Handling

Error handling in **InnoDB** is not always the same as specified in the SQL standard. According to the standard, any error during an SQL statement should cause the rollback of that statement. **InnoDB** sometimes rolls back only part of the statement, or the whole transaction. The following items describe how **InnoDB** performs error handling:

- If you run out of file space in the tablespace, a MySQL **Table is full** error occurs and **InnoDB** rolls back the SQL statement.
- A transaction deadlock causes **InnoDB** to roll back the entire transaction. In the case of a lock wait timeout, **InnoDB** rolls back only the most recent SQL statement.

When a transaction rollback occurs due to a deadlock or lock wait timeout, it cancels the effect of the statements within the transaction. But if the start-transaction statement was **START TRANSACTION** or **BEGIN** statement, rollback does not cancel that statement. Further SQL statements become part of the transaction until the occurrence of **COMMIT**, **ROLLBACK**, or some SQL statement that causes an implicit commit.

- A duplicate-key error rolls back the SQL statement, if you have not specified the **IGNORE** option in your statement.
- A **row too long error** rolls back the SQL statement.
- Other errors are mostly detected by the MySQL layer of code (above the **InnoDB** storage engine level), and they roll back the corresponding SQL statement. Locks are not released in a rollback of a single SQL statement.

During implicit rollbacks, as well as during the execution of an explicit `ROLLBACK` SQL command, `SHOW PROCESSLIST` displays `Rolling back` in the `State` column for the relevant connection.

14.5.15.1. InnoDB Error Codes

The following is a non-exhaustive list of common InnoDB-specific errors that you may encounter, with information about why each occurs and how to resolve the problem.

- 1005 (`ER_CANT_CREATE_TABLE`)

Cannot create table. If the error message refers to `errno` 150, table creation failed because a foreign key constraint was not correctly formed. If the error message refers to `errno` -1, table creation probably failed because the table includes a column name that matched the name of an internal InnoDB table.

- 1016 (`ER_CANT_OPEN_FILE`)

Cannot find the InnoDB table from the InnoDB data files, although the `.frm` file for the table exists. See [Section 14.5.17.1, “Troubleshooting InnoDB Data Dictionary Operations”](#).

- 1114 (`ER_RECORD_FILE_FULL`)

InnoDB has run out of free space in the tablespace. You should reconfigure the tablespace to add a new data file.

- 1205 (`ER_LOCK_WAIT_TIMEOUT`)

Lock wait timeout expired. Transaction was rolled back.

- 1213 (`ER_LOCK_DEADLOCK`)

Transaction deadlock. You should rerun the transaction.

- 1216 (`ER_NO_REFERENCED_ROW`)

You are trying to add a row but there is no parent row, and a foreign key constraint fails. You should add the parent row first.

- 1217 (`ER_ROW_IS_REFERENCED`)

You are trying to delete a parent row that has children, and a foreign key constraint fails. You should delete the children first.

14.5.15.2. Operating System Error Codes

To print the meaning of an operating system error number, use the `pererror` program that comes with the MySQL distribution.

The following table provides a list of some common Linux system error codes. For a more complete list, see [Linux source code](http://www.iglu.org.il/lxr/source/include/asm-i386/errno.h) [http://www.iglu.org.il/lxr/source/include/asm-i386/errno.h].

- 1 (`EPERM`)

Operation not permitted

- 2 (`ENOENT`)

No such file or directory

- 3 (ESRCH)

No such process

- 4 (EINTR)

Interrupted system call

- 5 (EIO)

I/O error

- 6 (ENXIO)

No such device or address

- 7 (E2BIG)

Arg list too long

- 8 (ENOEXEC)

Exec format error

- 9 (EBADF)

Bad file number

- 10 (ECHILD)

No child processes

- 11 (EAGAIN)

Try again

- 12 (ENOMEM)

Out of memory

- 13 (EACCES)

Permission denied

- 14 (EFAULT)

Bad address

- 15 (ENOTBLK)

Block device required

- 16 (EBUSY)

Device or resource busy

- 17 (EEXIST)

File exists

- 18 (EXDEV)

Cross-device link

- 19 (ENODEV)

No such device

- 20 (ENOTDIR)

Not a directory

- 21 (EISDIR)

Is a directory

- 22 (EINVAL)

Invalid argument

- 23 (ENFILE)

File table overflow

- 24 (EMFILE)

Too many open files

- 25 (ENOTTY)

Inappropriate ioctl for device

- 26 (ETXTBSY)

Text file busy

- 27 (EFBIG)

File too large

- 28 (ENOSPC)

No space left on device

- 29 (ESPIPE)

Illegal seek

- 30 (EROFS)

Read-only file system

- 31 (EMLINK)

Too many links

The following table provides a list of some common Windows system error codes. For a complete list see the [Microsoft Web site](http://msdn.microsoft.com/library/default.asp?url=/library/en-us/debug/base/system_error_codes.asp) [http://msdn.microsoft.com/library/default.asp?url=/library/en-us/debug/base/system_error_codes.asp].

- 1 (ERROR_INVALID_FUNCTION)
Incorrect function.
- 2 (ERROR_FILE_NOT_FOUND)
The system cannot find the file specified.
- 3 (ERROR_PATH_NOT_FOUND)
The system cannot find the path specified.
- 4 (ERROR_TOO_MANY_OPEN_FILES)
The system cannot open the file.
- 5 (ERROR_ACCESS_DENIED)
Access is denied.
- 6 (ERROR_INVALID_HANDLE)
The handle is invalid.
- 7 (ERROR_ARENA_TRASHED)
The storage control blocks were destroyed.
- 8 (ERROR_NOT_ENOUGH_MEMORY)
Not enough storage is available to process this command.
- 9 (ERROR_INVALID_BLOCK)
The storage control block address is invalid.
- 10 (ERROR_BAD_ENVIRONMENT)
The environment is incorrect.
- 11 (ERROR_BAD_FORMAT)
An attempt was made to load a program with an incorrect format.
- 12 (ERROR_INVALID_ACCESS)
The access code is invalid.
- 13 (ERROR_INVALID_DATA)
The data is invalid.
- 14 (ERROR_OUTOFMEMORY)
Not enough storage is available to complete this operation.

- 15 (`ERROR_INVALID_DRIVE`)
The system cannot find the drive specified.
- 16 (`ERROR_CURRENT_DIRECTORY`)
The directory cannot be removed.
- 17 (`ERROR_NOT_SAME_DEVICE`)
The system cannot move the file to a different disk drive.
- 18 (`ERROR_NO_MORE_FILES`)
There are no more files.
- 19 (`ERROR_WRITE_PROTECT`)
The media is write protected.
- 20 (`ERROR_BAD_UNIT`)
The system cannot find the device specified.
- 21 (`ERROR_NOT_READY`)
The device is not ready.
- 22 (`ERROR_BAD_COMMAND`)
The device does not recognize the command.
- 23 (`ERROR_CRC`)
Data error (cyclic redundancy check).
- 24 (`ERROR_BAD_LENGTH`)
The program issued a command but the command length is incorrect.
- 25 (`ERROR_SEEK`)
The drive cannot locate a specific area or track on the disk.
- 26 (`ERROR_NOT_DOS_DISK`)
The specified disk or diskette cannot be accessed.
- 27 (`ERROR_SECTOR_NOT_FOUND`)
The drive cannot find the sector requested.
- 28 (`ERROR_OUT_OF_PAPER`)
The printer is out of paper.
- 29 (`ERROR_WRITE_FAULT`)
The system cannot write to the specified device.

- 30 (`ERROR_READ_FAULT`)
The system cannot read from the specified device.
- 31 (`ERROR_GEN_FAILURE`)
A device attached to the system is not functioning.
- 32 (`ERROR_SHARING_VIOLATION`)
The process cannot access the file because it is being used by another process.
- 33 (`ERROR_LOCK_VIOLATION`)
The process cannot access the file because another process has locked a portion of the file.
- 34 (`ERROR_WRONG_DISK`)
The wrong diskette is in the drive. Insert %2 (Volume Serial Number: %3) into drive %1.
- 36 (`ERROR_SHARING_BUFFER_EXCEEDED`)
Too many files opened for sharing.
- 38 (`ERROR_HANDLE_EOF`)
Reached the end of the file.
- 39 (`ERROR_HANDLE_DISK_FULL`)
The disk is full.
- 87 (`ERROR_INVALID_PARAMETER`)
The parameter is incorrect. (If this error occurs on Windows and you have enabled `innodb_file_per_table` in a server option file, add the line `innodb_flush_method=unbuffered` to the file as well.)
- 112 (`ERROR_DISK_FULL`)
The disk is full.
- 123 (`ERROR_INVALID_NAME`)
The filename, directory name, or volume label syntax is incorrect.
- 1450 (`ERROR_NO_SYSTEM_RESOURCES`)
Insufficient system resources exist to complete the requested service.

14.5.16. Restrictions on InnoDB Tables

- **Warning:** Do *not* convert MySQL system tables in the `mysql` database from `MyISAM` to `InnoDB` tables! This is an unsupported operation. If you do this, MySQL does not restart until you restore the old system tables from a backup or re-generate them with the `mysql_install_db` script.
- A table cannot contain more than 1000 columns.

- The internal maximum key length is 3500 bytes, but MySQL itself restricts this to 1024 bytes.
- The maximum row length, except for `VARCHAR`, `BLOB` and `TEXT` columns, is slightly less than half of a database page. That is, the maximum row length is about 8000 bytes. `LONGBLOB` and `LONGTEXT` columns must be less than 4GB, and the total row length, including also `BLOB` and `TEXT` columns, must be less than 4GB. `InnoDB` stores the first 768 bytes of a `VARCHAR`, `BLOB`, or `TEXT` column in the row, and the rest into separate pages.
- Although `InnoDB` supports row sizes larger than 65535 internally, you cannot define a row containing `VARCHAR` columns with a combined size larger than 65535:

```
mysql> CREATE TABLE t (a VARCHAR(8000), b VARCHAR(10000),
-> c VARCHAR(10000), d VARCHAR(10000), e VARCHAR(10000),
-> f VARCHAR(10000), g VARCHAR(10000)) ENGINE=InnoDB;
ERROR 1118 (42000): Row size too large. The maximum row size for the
used table type, not counting BLOBs, is 65535. You have to change some
columns to TEXT or BLOBs
```

- On some older operating systems, files must be less than 2GB. This is not a limitation of `InnoDB` itself, but if you require a large tablespace, you will need to configure it using several smaller data files rather than one or a file large data files.
- The combined size of the `InnoDB` log files must be less than 4GB.
- The minimum tablespace size is 10MB. The maximum tablespace size is four billion database pages (64TB). This is also the maximum size for a table.
- `InnoDB` tables do not support `FULLTEXT` indexes.
- `ANALYZE TABLE` determines index cardinality (as displayed in the `Cardinality` column of `SHOW INDEX` output) by doing ten random dives to each of the index trees and updating index cardinality estimates accordingly. Note that because these are only estimates, repeated runs of `ANALYZE TABLE` may produce different numbers. This makes `ANALYZE TABLE` fast on `InnoDB` tables but not 100% accurate as it doesn't take all rows into account.

MySQL uses index cardinality estimates only in join optimization. If some join is not optimized in the right way, you can try using `ANALYZE TABLE`. In the few cases that `ANALYZE TABLE` doesn't produce values good enough for your particular tables, you can use `FORCE INDEX` with your queries to force the use of a particular index, or set the `max_seeks_for_key` system variable to ensure that MySQL prefers index lookups over table scans. See [Section 5.2.3, “System Variables”](#), and [Section A.6, “Optimizer-Related Issues”](#).

- `SHOW TABLE STATUS` does not give accurate statistics on `InnoDB` tables, except for the physical size reserved by the table. The row count is only a rough estimate used in SQL optimization.
- `InnoDB` does not keep an internal count of rows in a table. (In practice, this would be somewhat complicated due to multi-versioning.) To process a `SELECT COUNT(*) FROM t` statement, `InnoDB` must scan an index of the table, which takes some time if the index is not entirely in the buffer pool. To get a fast count, you have to use a counter table you create yourself and let your application update it according to the inserts and deletes it does. If your table does not change often, using the MySQL query cache is a good solution. `SHOW TABLE STATUS` also can be used if an approximate row count is sufficient. See [Section 14.5.11, “InnoDB Performance Tuning Tips”](#).
- On Windows, `InnoDB` always stores database and table names internally in lowercase. To move databases in binary format from Unix to Windows or from Windows to Unix, you should always use explicitly lowercase names when creating databases and tables.
- For an `AUTO_INCREMENT` column, you must always define an index for the table, and that index must contain just the `AUTO_INCREMENT` column. In `MyISAM` tables, the `AUTO_INCREMENT` column may be part of a multi-column index.

- While initializing a previously specified `AUTO_INCREMENT` column on a table, `InnoDB` sets an exclusive lock on the end of the index associated with the `AUTO_INCREMENT` column. In accessing the auto-increment counter, `InnoDB` uses a specific table lock mode `AUTO-INC` where the lock lasts only to the end of the current SQL statement, not to the end of the entire transaction. Note that other clients cannot insert into the table while the `AUTO-INC` table lock is held; see [Section 14.5.10.2, “InnoDB and AUTOCOMMIT”](#).
- When you restart the MySQL server, `InnoDB` may reuse an old value that was generated for an `AUTO_INCREMENT` column but never stored (that is, a value that was generated during an old transaction that was rolled back).
- When an `AUTO_INCREMENT` column runs out of values, `InnoDB` wraps a `BIGINT` to `-9223372036854775808` and `BIGINT UNSIGNED` to `1`. However, `BIGINT` values have 64 bits, so do note that if you were to insert one million rows per second, it would still take nearly three hundred thousand years before `BIGINT` reached its upper bound. With all other integer type columns, a duplicate-key error results. This is similar to how `MyISAM` works, because it is mostly general MySQL behavior and not about any storage engine in particular.
- `DELETE FROM tbl_name` does not regenerate the table but instead deletes all rows, one by one.
- Under some conditions, `TRUNCATE tbl_name` for an `InnoDB` table is mapped to `DELETE FROM tbl_name` and doesn't reset the `AUTO_INCREMENT` counter. See [Section 13.2.9, “TRUNCATE Syntax”](#).
- In MySQL 5.1, the MySQL `LOCK TABLES` operation acquires two locks on each table if `innodb_table_locks=1` (the default). In addition to a table lock on the MySQL layer, it also acquires an `InnoDB` table lock. Older versions of MySQL did not acquire `InnoDB` table locks; the old behavior can be selected by setting `innodb_table_locks=0`. If no `InnoDB` table lock is acquired, `LOCK TABLES` completes even if some records of the tables are being locked by other transactions.
- All `InnoDB` locks held by a transaction are released when the transaction is committed or aborted. Thus, it does not make much sense to invoke `LOCK TABLES` on `InnoDB` tables in `AUTOCOMMIT=1` mode, because the acquired `InnoDB` table locks would be released immediately.
- Sometimes it would be useful to lock further tables in the course of a transaction. Unfortunately, `LOCK TABLES` in MySQL performs an implicit `COMMIT` and `UNLOCK TABLES`. An `InnoDB` variant of `LOCK TABLES` has been planned that can be executed in the middle of a transaction.
- The `LOAD TABLE FROM MASTER` statement for setting up replication slave servers does not work for `InnoDB` tables. A workaround is to alter the table to `MyISAM` on the master, do then the load, and after that alter the master table back to `InnoDB`. Do not do this if the tables use `InnoDB`-specific features such as foreign keys.
- The default database page size in `InnoDB` is 16KB. By recompiling the code, you can set it to values ranging from 8KB to 64KB. You must update the values of `UNIV_PAGE_SIZE` and `UNIV_PAGE_SIZE_SHIFT` in the `univ.i` source file.
- Currently, triggers are not activated by cascaded foreign key actions.

14.5.17. InnoDB Troubleshooting

The following general guidelines apply to troubleshooting `InnoDB` problems:

- When an operation fails or you suspect a bug, you should look at the MySQL server error log, which is the file in the data directory that has a suffix of `.err`.

- When troubleshooting, it is usually best to run the MySQL server from the command prompt, rather than through the `mysqld_safe` wrapper or as a Windows service. You can then see what `mysqld` prints to the console, and so have a better grasp of what is going on. On Windows, you must start the server with the `--console` option to direct the output to the console window.
- Use the `InnoDB` Monitors to obtain information about a problem (see [Section 14.5.11.1, “SHOW ENGINE INNODB STATUS and the InnoDB Monitors”](#)). If the problem is performance-related, or your server appears to be hung, you should use `innodb_monitor` to print information about the internal state of `InnoDB`. If the problem is with locks, use `innodb_lock_monitor`. If the problem is in creation of tables or other data dictionary operations, use `innodb_table_monitor` to print the contents of the `InnoDB` internal data dictionary.
- If you suspect that a table is corrupt, run `CHECK TABLE` on that table.

14.5.17.1. Troubleshooting `InnoDB` Data Dictionary Operations

A specific issue with tables is that the MySQL server keeps data dictionary information in `.frm` files it stores in the database directories, whereas `InnoDB` also stores the information into its own data dictionary inside the tablespace files. If you move `.frm` files around, or if the server crashes in the middle of a data dictionary operation, the locations of the `.frm` files may end up out of synchrony with the locations recorded in the `InnoDB` internal data dictionary.

A symptom of an out-of-sync data dictionary is that a `CREATE TABLE` statement fails. If this occurs, you should look in the server's error log. If the log says that the table already exists inside the `InnoDB` internal data dictionary, you have an orphaned table inside the `InnoDB` tablespace files that has no corresponding `.frm` file. The error message looks like this:

```
InnoDB: Error: table test/parent already exists in InnoDB internal
InnoDB: data dictionary. Have you deleted the .frm file
InnoDB: and not used DROP TABLE? Have you used DROP DATABASE
InnoDB: for InnoDB tables in MySQL version <= 3.23.43?
InnoDB: See the Restrictions section of the InnoDB manual.
InnoDB: You can drop the orphaned table inside InnoDB by
InnoDB: creating an InnoDB table with the same name in another
InnoDB: database and moving the .frm file to the current database.
InnoDB: Then MySQL thinks the table exists, and DROP TABLE will
InnoDB: succeed.
```

You can drop the orphaned table by following the instructions given in the error message. If you are still unable to use `DROP TABLE` successfully, the problem may be due to name completion in the `mysql` client. To work around this problem, start the `mysql` client with the `--skip-auto-rehash` option and try `DROP TABLE` again. (With name completion on, `mysql` tries to construct a list of table names, which fails when a problem such as just described exists.)

Another symptom of an out-of-sync data dictionary is that MySQL prints an error that it cannot open a `.InnoDB` file:

```
ERROR 1016: Can't open file: 'child2.InnoDB'. (errno: 1)
```

In the error log you can find a message like this:

```
InnoDB: Cannot find table test/child2 from the internal data dictionary
InnoDB: of InnoDB though the .frm file for the table exists. Maybe you
InnoDB: have deleted and recreated InnoDB data files but have forgotten
InnoDB: to delete the corresponding .frm files of InnoDB tables?
```

This means that there is an orphaned `.frm` file without a corresponding table inside `InnoDB`. You can drop the orphaned `.frm` file by deleting it manually.

If MySQL crashes in the middle of an `ALTER TABLE` operation, you may end up with an orphaned temporary table inside the `InnoDB` tablespace. Using `innodb_table_monitor` you can see listed a table whose name is `#sql-...`. You can perform SQL statements on tables whose name contains the character `#` if you enclose the name within backticks. Thus, you can drop such an orphaned table like any other orphaned table using the method described earlier. Note that to copy or rename a file in the Unix shell, you need to put the file name in double quotes if the file name contains `#`.

14.6. The `MERGE` Storage Engine

The `MERGE` storage engine, also known as the `MRG_MyISAM` engine, is a collection of identical `MyISAM` tables that can be used as one. “Identical” means that all tables have identical column and index information. You cannot merge `MyISAM` tables in which the columns are listed in a different order, do not have exactly the same columns, or have the indexes in different order. However, any or all of the `MyISAM` tables can be compressed with `myisampack`. See [Section 8.5, “myisampack — Generate Compressed, Read-Only MyISAM Tables”](#). Differences in table options such as `AVG_ROW_LENGTH`, `MAX_ROWS`, or `PACK_KEYS` do not matter.

When you create a `MERGE` table, MySQL creates two files on disk. The files have names that begin with the table name and have an extension to indicate the file type. An `.frm` file stores the table format, and an `.MRG` file contains the names of the tables that should be used as one. The tables do not have to be in the same database as the `MERGE` table itself.

You can use `SELECT`, `DELETE`, `UPDATE`, and `INSERT` on `MERGE` tables. You must have `SELECT`, `UPDATE`, and `DELETE` privileges on the `MyISAM` tables that you map to a `MERGE` table.

Note: The use of `MERGE` tables entails the following security issue: If a user has access to `MyISAM` table `t`, that user can create a `MERGE` table `m` that accesses `t`. However, if the user's privileges on `t` are subsequently revoked, the user can continue to access `t` by doing so through `m`. If this behavior is undesirable, you can start the server with the new `--skip-merge` option to disable the `MERGE` storage engine. This option is available as of MySQL 5.1.12.

If you `DROP` the `MERGE` table, you are dropping only the `MERGE` specification. The underlying tables are not affected.

To create a `MERGE` table, you must specify a `UNION=(list-of-tables)` clause that indicates which `MyISAM` tables you want to use as one. You can optionally specify an `INSERT_METHOD` option if you want inserts for the `MERGE` table to take place in the first or last table of the `UNION` list. Use a value of `FIRST` or `LAST` to cause inserts to be made in the first or last table, respectively. If you do not specify an `INSERT_METHOD` option or if you specify it with a value of `NO`, attempts to insert rows into the `MERGE` table result in an error.

The following example shows how to create a `MERGE` table:

```
mysql> CREATE TABLE t1 (
->   a INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
->   message CHAR(20)) ENGINE=MyISAM;
mysql> CREATE TABLE t2 (
->   a INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
->   message CHAR(20)) ENGINE=MyISAM;
mysql> INSERT INTO t1 (message) VALUES ('Testing'),('table'),('t1');
mysql> INSERT INTO t2 (message) VALUES ('Testing'),('table'),('t2');
mysql> CREATE TABLE total (
->   a INT NOT NULL AUTO_INCREMENT,
->   message CHAR(20), INDEX(a))
->   ENGINE=MERGE UNION=(t1,t2) INSERT_METHOD=LAST;
```

Note that the `a` column is indexed as a `PRIMARY KEY` in the underlying `MyISAM` tables, but not in the `MERGE` table. There it is indexed but not as a `PRIMARY KEY` because a `MERGE` table cannot enforce uniqueness over the set of underlying tables.

After creating the `MERGE` table, you can issue queries that operate on the group of tables as a whole:

```
mysql> SELECT * FROM total;
+-----+-----+
| a | message |
+-----+-----+
| 1 | Testing |
| 2 | table   |
| 3 | t1      |
| 1 | Testing |
| 2 | table   |
| 3 | t2      |
+-----+-----+
```

To remap a `MERGE` table to a different collection of `MyISAM` tables, you can use one of the following methods:

- `DROP` the `MERGE` table and re-create it.
- Use `ALTER TABLE tbl_name UNION=(. . .)` to change the list of underlying tables.

`MERGE` tables can help you solve the following problems:

- Easily manage a set of log tables. For example, you can put data from different months into separate tables, compress some of them with `myisampack`, and then create a `MERGE` table to use them as one.
- Obtain more speed. You can split a big read-only table based on some criteria, and then put individual tables on different disks. A `MERGE` table on this could be much faster than using the big table.
- Perform more efficient searches. If you know exactly what you are looking for, you can search in just one of the split tables for some queries and use a `MERGE` table for others. You can even have many different `MERGE` tables that use overlapping sets of tables.
- Perform more efficient repairs. It is easier to repair individual tables that are mapped to a `MERGE` table than to repair a single large table.
- Instantly map many tables as one. A `MERGE` table need not maintain an index of its own because it uses the indexes of the individual tables. As a result, `MERGE` table collections are *very* fast to create or remap. (Note that you must still specify the index definitions when you create a `MERGE` table, even though no indexes are created.)
- If you have a set of tables from which you create a large table on demand, you should instead create a `MERGE` table on them on demand. This is much faster and saves a lot of disk space.
- Exceed the file size limit for the operating system. Each `MyISAM` table is bound by this limit, but a collection of `MyISAM` tables is not.
- You can create an alias or synonym for a `MyISAM` table by defining a `MERGE` table that maps to that single table. There should be no really notable performance impact from doing this (only a couple of indirect calls and `memcpy()` calls for each read).

The disadvantages of `MERGE` tables are:

- You can use only identical `MyISAM` tables for a `MERGE` table.
- You cannot use a number of `MyISAM` features in `MERGE` tables. For example, you cannot create

`FULLTEXT` indexes on `MERGE` tables. (You can, of course, create `FULLTEXT` indexes on the underlying `MyISAM` tables, but you cannot search the `MERGE` table with a full-text search.)

- If the `MERGE` table is non-temporary, all underlying `MyISAM` tables must be non-temporary, too. If the `MERGE` table is temporary, the `MyISAM` tables can be any mix of temporary and non-temporary.
- `MERGE` tables use more file descriptors. If 10 clients are using a `MERGE` table that maps to 10 tables, the server uses $(10 \times 10) + 10$ file descriptors. (10 data file descriptors for each of the 10 clients, and 10 index file descriptors shared among the clients.)
- Key reads are slower. When you read a key, the `MERGE` storage engine needs to issue a read on all underlying tables to check which one most closely matches the given key. To read the next key, the `MERGE` storage engine needs to search the read buffers to find the next key. Only when one key buffer is used up does the storage engine need to read the next key block. This makes `MERGE` keys much slower on `eq_ref` searches, but not much slower on `ref` searches. See [Section 7.2.1, “Optimizing Queries with EXPLAIN”](#), for more information about `eq_ref` and `ref`.

Additional resources

- A forum dedicated to the `MERGE` storage engine is available at <http://forums.mysql.com/list.php?93>.

14.6.1. `MERGE` Table Problems

The following are known problems with `MERGE` tables:

- If you use `ALTER TABLE` to change a `MERGE` table to another storage engine, the mapping to the underlying tables is lost. Instead, the rows from the underlying `MyISAM` tables are copied into the altered table, which then uses the specified storage engine.
- `REPLACE` does not work.
- `MERGE` tables do not support partitioning. That is, you cannot partition a `MERGE` table, nor can any of a `MERGE` table's underlying `MyISAM` tables be partitioned.
- You cannot use `DROP TABLE`, `ALTER TABLE`, `DELETE` without a `WHERE` clause, `REPAIR TABLE`, `TRUNCATE TABLE`, `OPTIMIZE TABLE`, or `ANALYZE TABLE` on any of the tables that are mapped into an open `MERGE` table. If you do so, the `MERGE` table may still refer to the original table, which yields unexpected results. The easiest way to work around this deficiency is to ensure that no `MERGE` tables remain open by issuing a `FLUSH TABLES` statement prior to performing any of those operations.
- `DROP TABLE` on a table that is in use by a `MERGE` table does not work on Windows because the `MERGE` storage engine's table mapping is hidden from the upper layer of MySQL. Windows does not allow open files to be deleted, so you first must flush all `MERGE` tables (with `FLUSH TABLES`) or drop the `MERGE` table before dropping the table.
- A `MERGE` table cannot maintain uniqueness constraints over the entire table. When you perform an `INSERT`, the data goes into the first or last `MyISAM` table (depending on the value of the `INSERT_METHOD` option). MySQL ensures that unique key values remain unique within that `MyISAM` table, but not across all the tables in the collection.
- When you create or alter `MERGE` table, there is no check to ensure that the underlying tables are existing `MyISAM` tables and have identical structures. When the `MERGE` table is used, MySQL checks that the row length for all mapped tables is equal, but this is not foolproof. If you create a `MERGE` ta-

ble from dissimilar `MyISAM` tables, you are very likely to run into strange problems.

Similarly, if you create a `MERGE` table from non-`MyISAM` tables, or if you drop an underlying table or alter it to be a non-`MyISAM` table, no error for the `MERGE` table occurs until later when you attempt to use it.

- The order of indexes in the `MERGE` table and its underlying tables should be the same. If you use `ALTER TABLE` to add a `UNIQUE` index to a table used in a `MERGE` table, and then use `ALTER TABLE` to add a non-unique index on the `MERGE` table, the index ordering is different for the tables if there was already a non-unique index in the underlying table. (This happens because `ALTER TABLE` puts `UNIQUE` indexes before non-unique indexes to facilitate rapid detection of duplicate keys.) Consequently, queries on tables with such indexes may return unexpected results.
- If you encounter an error message similar to `ERROR 1017 (HY000): Can't find file: 'mm.MRG' (errno: 2)` it generally indicates that some of the base tables are not using the `MyISAM` storage engine. Confirm that all tables are `MyISAM`.
- There is a limit of 2^{32} (~4.295E+09) rows to a `MERGE` table, just as there is with a `MyISAM`, it is therefore not possible to merge multiple `MyISAM` tables that exceed this limitation. However, you build MySQL with the `--with-big-tables` option then the row limitation is increased to $(2^{32})^2$ (1.844E+19) rows. See [Section 2.9.2, “Typical configure Options”](#). Beginning with MySQL 5.0.4 all standard binaries are built with this option.

14.7. The `MEMORY (HEAP)` Storage Engine

The `MEMORY` storage engine creates tables with contents that are stored in memory. Formerly, these were known as `HEAP` tables. `MEMORY` is the preferred term, although `HEAP` remains supported for backward compatibility.

Each `MEMORY` table is associated with one disk file. The filename begins with the table name and has an extension of `.frm` to indicate that it stores the table definition.

To specify explicitly that you want to create a `MEMORY` table, indicate that with an `ENGINE` table option:

```
CREATE TABLE t (i INT) ENGINE = MEMORY;
```

As indicated by the name, `MEMORY` tables are stored in memory. They use hash indexes by default, which makes them very fast, and very useful for creating temporary tables. However, when the server shuts down, all rows stored in `MEMORY` tables are lost. The tables themselves continue to exist because their definitions are stored in `.frm` files on disk, but they are empty when the server restarts.

This example shows how you might create, use, and remove a `MEMORY` table:

```
mysql> CREATE TABLE test ENGINE=MEMORY
->     SELECT ip,SUM(downloads) AS down
->     FROM log_table GROUP BY ip;
mysql> SELECT COUNT(ip),AVG(down) FROM test;
mysql> DROP TABLE test;
```

`MEMORY` tables have the following characteristics:

- Space for `MEMORY` tables is allocated in small blocks. Tables use 100% dynamic hashing for inserts. No overflow area or extra key space is needed. No extra space is needed for free lists. Deleted rows are put in a linked list and are reused when you insert new data into the table. `MEMORY` tables also have none of the problems commonly associated with deletes plus inserts in hashed tables.

- `MEMORY` tables can have up to 32 indexes per table, 16 columns per index and a maximum key length of 500 bytes.
- The `MEMORY` storage engine implements both `HASH` and `BTREE` indexes. You can specify one or the other for a given index by adding a `USING` clause as shown here:

```
CREATE TABLE lookup
  (id INT, INDEX USING HASH (id))
ENGINE = MEMORY;
CREATE TABLE lookup
  (id INT, INDEX USING BTREE (id))
ENGINE = MEMORY;
```

General characteristics of B-tree and hash indexes are described in [Section 7.4.5, “How MySQL Uses Indexes”](#).

- You can have non-unique keys in a `MEMORY` table. (This is an uncommon feature for implementations of hash indexes.)
- If you have a hash index on a `MEMORY` table that has a high degree of key duplication (many index entries containing the same value), updates to the table that affect key values and all deletes are significantly slower. The degree of this slowdown is proportional to the degree of duplication (or, inversely proportional to the index cardinality). You can use a `BTREE` index to avoid this problem.
- Columns that are indexed can contain `NULL` values.
- `MEMORY` tables use a fixed-length row storage format.
- `MEMORY` tables cannot contain `BLOB` or `TEXT` columns.
- `MEMORY` includes support for `AUTO_INCREMENT` columns.
- You can use `INSERT DELAYED` with `MEMORY` tables. See [Section 13.2.4.2, “INSERT DELAYED Syntax”](#).
- `MEMORY` tables are shared among all clients (just like any other non-`TEMPORARY` table).
- `MEMORY` table contents are stored in memory, which is a property that `MEMORY` tables share with internal tables that the server creates on the fly while processing queries. However, the two types of tables differ in that `MEMORY` tables are not subject to storage conversion, whereas internal tables are:
 - If an internal table becomes too large, the server automatically converts it to an on-disk table. The size limit is determined by the value of the `tmp_table_size` system variable.
 - `MEMORY` tables are never converted to disk tables. To ensure that you don't accidentally do anything foolish, you can set the `max_heap_table_size` system variable to impose a maximum size on `MEMORY` tables. For individual tables, you can also specify a `MAX_ROWS` table option in the `CREATE TABLE` statement.
- The server needs sufficient memory to maintain all `MEMORY` tables that are in use at the same time.
- To free memory used by a `MEMORY` table when you no longer require its contents, you should execute `DELETE` or `TRUNCATE TABLE`, or remove the table altogether using `DROP TABLE`.
- If you want to populate a `MEMORY` table when the MySQL server starts, you can use the `-init-file` option. For example, you can put statements such as `INSERT INTO ... SELECT` or `LOAD DATA INFILE` into this file to load the table from a persistent data source. See [Section 5.2.2, “Command Options”](#), and [Section 13.2.5, “LOAD DATA INFILE Syntax”](#).
- If you are using replication, the master server's `MEMORY` tables become empty when it is shut down

and restarted. However, a slave is not aware that these tables have become empty, so it returns out-of-date content if you select data from them. When a `MEMORY` table is used on the master for the first time since the master was started, a `DELETE` statement is written to the master's binary log automatically, thus synchronizing the slave to the master again. Note that even with this strategy, the slave still has outdated data in the table during the interval between the master's restart and its first use of the table. However, if you use the `--init-file` option to populate the `MEMORY` table on the master at startup, it ensures that this time interval is zero.

- The memory needed for one row in a `MEMORY` table is calculated using the following expression:

```
SUM_OVER_ALL_BTREE_KEYS(max_length_of_key + sizeof(char*) × 4)
+ SUM_OVER_ALL_HASH_KEYS(sizeof(char*) × 2)
+ ALIGN(length_of_row+1, sizeof(char*))
```

`ALIGN()` represents a round-up factor to cause the row length to be an exact multiple of the `char` pointer size. `sizeof(char*)` is 4 on 32-bit machines and 8 on 64-bit machines.

Additional resources

- A forum dedicated to the `MEMORY` storage engine is available at <http://forums.mysql.com/list.php?92>.

14.8. The `EXAMPLE` Storage Engine

The `EXAMPLE` storage engine is a stub engine that does nothing. Its purpose is to serve as an example in the MySQL source code that illustrates how to begin writing new storage engines. As such, it is primarily of interest to developers.

The `EXAMPLE` storage engine is included in MySQL-Max binary distributions. To enable this storage engine if you build MySQL from source, invoke `configure` with the `--with-example-storage-engine` option.

To examine the source for the `EXAMPLE` engine, look in the `storage/example` directory of a MySQL source distribution.

When you create an `EXAMPLE` table, the server creates a table format file in the database directory. The file begins with the table name and has an `.frm` extension. No other files are created. No data can be stored into the table. Retrievals return an empty result.

```
mysql> CREATE TABLE test (i INT) ENGINE = EXAMPLE;
Query OK, 0 rows affected (0.78 sec)

mysql> INSERT INTO test VALUES(1),(2),(3);
ERROR 1031 (HY000): Table storage engine for 'test' doesn't »
      have this option

mysql> SELECT * FROM test;
Empty set (0.31 sec)
```

The `EXAMPLE` storage engine does not support indexing.

14.9. The `FEDERATED` Storage Engine

The `FEDERATED` storage engine accesses data in tables of remote databases rather than in local tables.

The `FEDERATED` storage engine is included in MySQL-Max binary distributions. To enable this storage

engine if you build MySQL from source, invoke `configure` with the `-with-federated-storage-engine` option.

To examine the source for the `FEDERATED` engine, look in the `sql` directory of a MySQL source distribution.

Additional resources

- A forum dedicated to the `FEDERATED` storage engine is available at <http://forums.mysql.com/list.php?105>.

14.9.1. Description of the `FEDERATED` Storage Engine

When you create a `FEDERATED` table, the server creates a table format file in the database directory. The file begins with the table name and has an `.frm` extension. No other files are created, because the actual data is in a remote table. This differs from the way that storage engines for local tables work.

For local database tables, data files are local. For example, if you create a `MyISAM` table named `users`, the `MyISAM` handler creates a data file named `users.MYD`. A handler for local tables reads, inserts, deletes, and updates data in local data files, and rows are stored in a format particular to the handler. To read rows, the handler must parse data into columns. To write rows, column values must be converted to the row format used by the handler and written to the local data file.

With the MySQL `FEDERATED` storage engine, there are no local data files for a table (for example, there is no `.MYD` file). Instead, a remote database stores the data that normally would be in the table. The local server connects to a remote server, and uses the MySQL client API to read, delete, update, and insert data in the remote table. Data retrieval is initiated via a `SELECT * FROM tbl_name` SQL statement. To read the result, rows are fetched one at a time by using the `mysql_fetch_row()` C API function, and then converting the columns in the `SELECT` result set to the format that the `FEDERATED` handler expects.

The flow of information is as follows:

1. SQL calls issued locally
2. MySQL handler API (data in handler format)
3. MySQL client API (data converted to SQL calls)
4. Remote database -> MySQL client API
5. Convert result sets (if any) to handler format
6. Handler API -> Result rows or rows-affected count to local

14.9.2. How to use `FEDERATED` Tables

The procedure for using `FEDERATED` tables is very simple. Normally, you have two servers running, either both on the same host or on different hosts. (It is possible for a `FEDERATED` table to use another table that is managed by the same server, although there is little point in doing so.)

First, you must have a table on the remote server that you want to access by using a `FEDERATED` table. Suppose that the remote table is in the `federated` database and is defined like this:

```
CREATE TABLE test_table (  
  id      INT(20) NOT NULL AUTO_INCREMENT,
```

```

name VARCHAR(32) NOT NULL DEFAULT '',
other INT(20) NOT NULL DEFAULT '0',
PRIMARY KEY (id),
INDEX name (name),
INDEX other_key (other)
)
ENGINE=MyISAM
DEFAULT CHARSET=latin1;

```

The example uses a [MyISAM](#) table, but the table could use any storage engine.

Next, create a [FEDERATED](#) table on the local server for accessing the remote table:

```

CREATE TABLE federated_table (
  id INT(20) NOT NULL AUTO_INCREMENT,
  name VARCHAR(32) NOT NULL DEFAULT '',
  other INT(20) NOT NULL DEFAULT '0',
  PRIMARY KEY (id),
  INDEX name (name),
  INDEX other_key (other)
)
ENGINE=FEDERATED
DEFAULT CHARSET=latin1
CONNECTION='mysql://root@remote_host:9306/federated/test_table';

```

(**Note:** [CONNECTION](#) replaces the [COMMENT](#) used in some previous versions of MySQL.)

The structure of this table must be exactly the same as that of the remote table, except that the [ENGINE](#) table option should be [FEDERATED](#) and the [CONNECTION](#) table option is a connection string that indicates to the [FEDERATED](#) engine how to connect to the remote server.

The [FEDERATED](#) engine creates only the `test_table.frm` file in the `federated` database.

The remote host information indicates the remote server to which your local server connects, and the database and table information indicates which remote table to use as the data source. In this example, the remote server is indicated to be running as `remote_host` on port 9306, so there must be a MySQL server running on the remote host and listening to port 9306.

The general form of the connection string in the [CONNECTION](#) option is as follows:

```

scheme://user_name[:password]@host_name[:port_num]/db_name/tbl_name

```

Only `mysql` is supported as the `scheme` value at this point; the password and port number are optional.

Here are some example connection strings:

```

CONNECTION='mysql://username:password@hostname:port/database/tablename'
CONNECTION='mysql://username@hostname/database/tablename'
CONNECTION='mysql://username:password@hostname/database/tablename'

```

The use of [CONNECTION](#) for specifying the connection string is non-optimal and is likely to change in future. Keep this in mind for applications that use [FEDERATED](#) tables. Such applications are likely to need modification if the format for specifying connection information changes.

Because any password given in the connection string is stored as plain text, it can be seen by any user who can use [SHOW CREATE TABLE](#) or [SHOW TABLE STATUS](#) for the [FEDERATED](#) table, or query the [TABLES](#) table in the [INFORMATION_SCHEMA](#) database.

14.9.3. Limitations of the [FEDERATED](#) Storage Engine

The following items indicate features that the [FEDERATED](#) storage engine does and does not support:

- In the first version, the remote server must be a MySQL server. Support by `FEDERATED` for other database engines may be added in the future.
- The remote table that a `FEDERATED` table points to *must* exist before you try to access the table through the `FEDERATED` table.
- It is possible for one `FEDERATED` table to point to another, but you must be careful not to create a loop.
- There is no support for transactions.
- There is no way for the `FEDERATED` engine to know if the remote table has changed. The reason for this is that this table must work like a data file that would never be written to by anything other than the database. The integrity of the data in the local table could be breached if there was any change to the remote database.
- The `FEDERATED` storage engine supports `SELECT`, `INSERT`, `UPDATE`, `DELETE`, and indexes. It does not support `ALTER TABLE`, or any Data Definition Language statements other than `DROP TABLE`. The current implementation does not use Prepared statements.
- Any `DROP TABLE` statement issued against a `FEDERATED` table will only drop the local table, not the remote table.
- The implementation uses `SELECT`, `INSERT`, `UPDATE`, and `DELETE`, but not `HANDLER`.
- `FEDERATED` tables do not work with the query cache.

Some of these limitations may be lifted in future versions of the `FEDERATED` handler.

14.10. The `ARCHIVE` Storage Engine

The `ARCHIVE` storage engine is used for storing large amounts of data without indexes in a very small footprint.

The `ARCHIVE` storage engine is included in MySQL binary distributions. To enable this storage engine if you build MySQL from source, invoke `configure` with the `-with-archive-storage-engine` option.

To examine the source for the `ARCHIVE` engine, look in the `storage/archive` directory of a MySQL source distribution.

You can check whether the `ARCHIVE` storage engine is available with this statement:

```
mysql> SHOW VARIABLES LIKE 'have_archive';
```

When you create an `ARCHIVE` table, the server creates a table format file in the database directory. The file begins with the table name and has an `.frm` extension. The storage engine creates other files, all having names beginning with the table name. The data and metadata files have extensions of `.ARZ` and `.ARM`, respectively. An `.ARN` file may appear during optimization operations.

The `ARCHIVE` engine supports `INSERT` and `SELECT`, but not `DELETE`, `REPLACE`, or `UPDATE`. It does support `ORDER BY` operations, `BLOB` columns, and basically all but spatial data types (see [Section 17.4.1, “MySQL Spatial Data Types”](#)). The `ARCHIVE` engine uses row-level locking.

As of MySQL 5.1.6, the `ARCHIVE` engine supports the `AUTO_INCREMENT` column attribute. The `AUTO_INCREMENT` columns can have either a unique or non-unique index. Attempting to create an index on any other column results in an error. The `ARCHIVE` engine also supports the

`AUTO_INCREMENT` table option in `CREATE TABLE` and `ALTER TABLE` statements to specify the initial sequence value for a new table or reset the sequence value for an existing table, respectively.

As of MySQL 5.1.6, the `ARCHIVE` engine ignores `BLOB` columns if they are not requested and scans past them while reading. Formerly, the following two statements had the same cost, but as of 5.1.6, the second is much more efficient than the first:

```
SELECT a, b, blob_col FROM archive_table;  
SELECT a, b FROM archive_table;
```

Storage: Rows are compressed as they are inserted. The `ARCHIVE` engine uses `zlib` lossless data compression (see <http://www.zlib.net/>). You can use `OPTIMIZE TABLE` to analyze the table and pack it into a smaller format (for a reason to use `OPTIMIZE TABLE`, see later in this section). The engine also supports `CHECK TABLE`. There are several types of insertions that are used:

- An `INSERT` statement just pushes rows into a compression buffer, and that buffer flushes as necessary. The insertion into the buffer is protected by a lock. A `SELECT` forces a flush to occur, unless the only insertions that have come in were `INSERT DELAYED` (those flush as necessary). See [Section 13.2.4.2, “INSERT DELAYED Syntax”](#).
- A bulk insert is visible only after it completes, unless other inserts occur at the same time, in which case it can be seen partially. A `SELECT` never causes a flush of a bulk insert unless a normal insert occurs while it is loading.

Retrieval: On retrieval, rows are uncompressed on demand; there is no row cache. A `SELECT` operation performs a complete table scan: When a `SELECT` occurs, it finds out how many rows are currently available and reads that number of rows. `SELECT` is performed as a consistent read. Note that lots of `SELECT` statements during insertion can deteriorate the compression, unless only bulk or delayed inserts are used. To achieve better compression, you can use `OPTIMIZE TABLE` or `REPAIR TABLE`. The number of rows in `ARCHIVE` tables reported by `SHOW TABLE STATUS` is always accurate. See [Section 13.5.2.5, “OPTIMIZE TABLE Syntax”](#), [Section 13.5.2.6, “REPAIR TABLE Syntax”](#), and [Section 13.5.4.26, “SHOW TABLE STATUS Syntax”](#).

Additional resources

- A forum dedicated to the `ARCHIVE` storage engine is available at <http://forums.mysql.com/list.php?112>.

14.11. The `CSV` Storage Engine

The `CSV` storage engine stores data in text files using comma-separated values format.

To enable this storage engine, use the `--with-csv-storage-engine` option to `configure` when you build MySQL.

The `CSV` storage engine is included in MySQL-Max binary distributions. To enable this storage engine if you build MySQL from source, invoke `configure` with the `--with-csv-storage-engine` option.

To examine the source for the `CSV` engine, look in the `storage/csv` directory of a MySQL source distribution.

When you create a `CSV` table, the server creates a table format file in the database directory. The file begins with the table name and has an `.frm` extension. The storage engine also creates a data file. Its name begins with the table name and has a `.CSV` extension. The data file is a plain text file. When you

store data into the table, the storage engine saves it into the data file in comma-separated values format.

```
mysql> CREATE TABLE test(i INT, c CHAR(10)) ENGINE = CSV;
Query OK, 0 rows affected (0.12 sec)

mysql> INSERT INTO test VALUES(1,'record one'),(2,'record two');
Query OK, 2 rows affected (0.00 sec)
Records: 2 Duplicates: 0 Warnings: 0

mysql> SELECT * FROM test;
+-----+-----+
| i     | c           |
+-----+-----+
| 1     | record one  |
| 2     | record two  |
+-----+-----+
2 rows in set (0.00 sec)
```

Starting with MySQL 5.1.9, creating a CSV table also creates a corresponding Meta-file that stores the state of the table and the number of rows that exist in the table. The name of this file is the same as the name of the table with the extension `CSM`.

If you examine the `test.CSV` file in the database directory created by executing the preceding statements, its contents should look like this:

```
"1", "record one"
"2", "record two"
```

This format can be read, and even written, by spreadsheet applications such as Microsoft Excel or StarOffice Calc.

14.11.1. Repairing and Checking CSV Tables

Functionality introduced in version 5.1.9

The CSV storage engines supports the `CHECK` and `REPAIR` commands to verify and if possible repair a damaged CSV table.

When running the `CHECK` command, the CSV file will be checked for validity by looking for the correct field separators, escaped fields (matching quotes and/or missing quotes), the correct number of fields compared to the table definition and the existence of a corresponding CSV metafile. The first invalid row discovered will report an error. Checking a valid table produces output like that shown below:

```
mysql> check table csvtest;
+-----+-----+-----+-----+
| Table          | Op      | Msg_type | Msg_text |
+-----+-----+-----+-----+
| test.csvtest   | check   | status   | OK       |
+-----+-----+-----+-----+
1 row in set (0.00 sec)
```

A check on a corrupted table returns a fault:

```
mysql> check table csvtest;
+-----+-----+-----+-----+
| Table          | Op      | Msg_type | Msg_text |
+-----+-----+-----+-----+
| test.csvtest   | check   | error    | Corrupt  |
+-----+-----+-----+-----+
1 row in set (0.01 sec)
```

If the check fails, the table is marked as crashed (corrupt). Once a table has been marked as corrupt, it is automatically repaired when you next run `CHECK` or execute a `SELECT` statement. The corresponding corrupt status and new status will be displayed when running `CHECK`:

```
mysql> check table csvtest;
+-----+-----+-----+-----+
| Table      | Op      | Msg_type | Msg_text |
+-----+-----+-----+-----+
| test.csvtest | check   | warning  | Table is marked as crashed |
| test.csvtest | check   | status   | OK       |
+-----+-----+-----+-----+
2 rows in set (0.08 sec)
```

To repair a table you can use [REPAIR](#), this copies as many valid rows from the existing CSV data as possible, and then replaces the existing CSV file with the recovered rows. Any rows beyond the corrupted data are lost.

```
mysql> repair table csvtest;
+-----+-----+-----+-----+
| Table      | Op      | Msg_type | Msg_text |
+-----+-----+-----+-----+
| test.csvtest | repair  | status   | OK       |
+-----+-----+-----+-----+
1 row in set (0.02 sec)
```

Warning

Note that during repair, only the rows from the CSV file up to the first damaged row are copied to the new table. All other rows, even valid rows, up to the first damaged row are removed.

14.11.2. CSV Limitations

Important: The [CSV](#) storage engine does not support indexing.

Partitioning is not supported for tables using the [CSV](#) storage engine. Beginning with MySQL 5.1.12, it is no longer possible to create partitioned [CSV](#) tables. (See [Bug#19307](#) [<http://bugs.mysql.com/19307>])

14.12. The [BLACKHOLE](#) Storage Engine

The [BLACKHOLE](#) storage engine acts as a “black hole” that accepts data but throws it away and does not store it. Retrievals always return an empty result:

```
mysql> CREATE TABLE test(i INT, c CHAR(10)) ENGINE = BLACKHOLE;
Query OK, 0 rows affected (0.03 sec)

mysql> INSERT INTO test VALUES(1,'record one'),(2,'record two');
Query OK, 2 rows affected (0.00 sec)
Records: 2 Duplicates: 0 Warnings: 0

mysql> SELECT * FROM test;
Empty set (0.00 sec)
```

The [BLACKHOLE](#) storage engine is included in MySQL-Max binary distributions. To enable this storage engine if you build MySQL from source, invoke [configure](#) with the `--with-blackhole-storage-engine` option.

To examine the source for the [BLACKHOLE](#) engine, look in the `sql` directory of a MySQL source distribution.

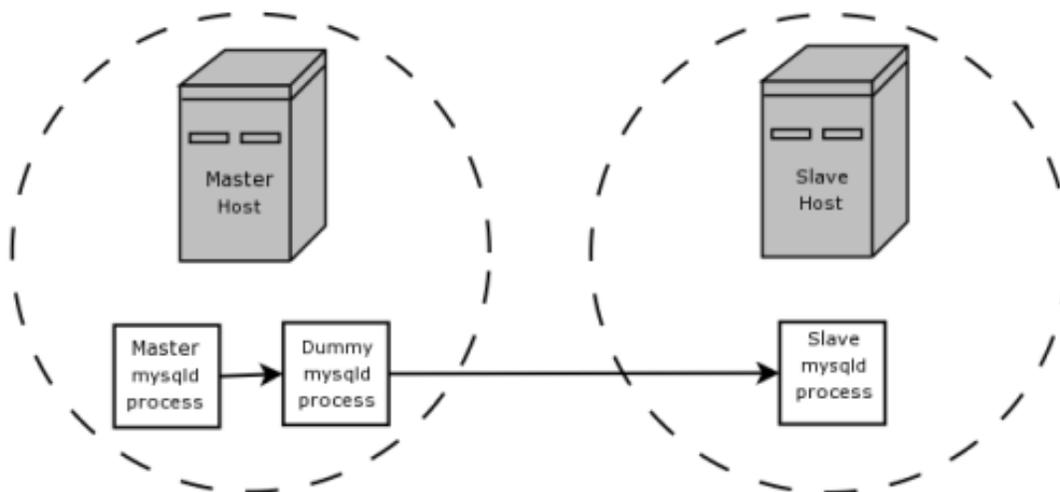

When you create a [BLACKHOLE](#) table, the server creates a table format file in the database directory. The file begins with the table name and has an `.frm` extension. There are no other files associated with the table.

The [BLACKHOLE](#) storage engine supports all kinds of indexes. That is, you can include index declarations in the table definition.

You can check whether the `BLACKHOLE` storage engine is available with this statement:

```
mysql> SHOW VARIABLES LIKE 'have_blackhole_engine';
```

Inserts into a `BLACKHOLE` table do not store any data, but if the binary log is enabled, the SQL statements are logged (and replicated to slave servers). This can be useful as a repeater or filter mechanism. For example, suppose that your application requires slave-side filtering rules, but transferring all binary log data to the slave first results in too much traffic. In such a case, it is possible to set up on the master host a “dummy” slave process whose default storage engine is `BLACKHOLE`, depicted as follows:

The master writes to its binary log. The “dummy” `mysqld` process acts as a slave, applying the desired combination of `replicate-do-*` and `replicate-ignore-*` rules, and writes a new, filtered binary log of its own. (See [Section 6.9, “Replication Startup Options”](#).) This filtered log is provided to the slave.

The dummy process does not actually store any data, so there is little processing overhead incurred by running the additional `mysqld` process on the replication master host. This type of setup can be repeated with additional replication slaves.

Other possible uses for the `BLACKHOLE` storage engine include:

- Verification of dump file syntax.
- Measurement of the overhead from binary logging, by comparing performance using `BLACKHOLE` with and without binary logging enabled.
- `BLACKHOLE` is essentially a “no-op” storage engine, so it could be used for finding performance bottlenecks not related to the storage engine itself.

As of MySQL 5.1.4, the `BLACKHOLE` engine is transaction-aware, in the sense that committed transactions are written to the binary log and rolled-back transactions are not.

Chapter 15. MySQL Cluster

MySQL Cluster is a high-availability, high-redundancy version of MySQL adapted for the distributed computing environment. It uses the [NDB Cluster](#) storage engine to enable running several MySQL servers in a cluster. This storage engine is available in MySQL 5.1 binary releases and in RPMs compatible with most modern Linux distributions.

MySQL Cluster is currently available and supported on the following platforms:

- **Linux:** x86, AMD64, EMT64, s/390, PPC, Alpha, SPARC, UltraSparc
- **Solaris:** SPARC, UltraSparc, x86, AMD64, EMT64
- **BSD** (FreeBSD, NetBSD, OpenBSD): x86, AMD64, EMT64, PPC
- **Mac OS X:** PPC
- **HP-UX:** PA-RISC
- **Tru64:** Alpha
- **OpenVMS:** Alpha
- **IRIX:** MIPS
- **Novell Netware:** x86
- **QNX Neutrino:** x86
- **SCO OpenServer, OpenUnix, UnixWare:** x86

For exact levels of support available for MySQL Cluster on specific combinations of operating system versions, operating system distributions, and hardware platforms, please refer to the [Cluster Supported Platforms list](http://www.mysql.com/support/clusterplatforms.html) [http://www.mysql.com/support/clusterplatforms.html] maintained by the MySQL Support Team on the MySQL AB website.

MySQL Cluster is *not* currently supported on Microsoft Windows. We are working to make Cluster available on all operating systems supported by MySQL, including Windows, and will update the information provided here as this work continues.

This chapter represents a work in progress, and its contents are subject to revision as MySQL Cluster continues to evolve. Additional information regarding MySQL Cluster can be found on the MySQL AB Web site at <http://www.mysql.com/products/cluster/>.

Additional resources

- Answers to some commonly asked questions about Cluster may be found in the [Section 15.15, “MySQL Cluster FAQ”](#).
- The MySQL Cluster mailing list: <http://lists.mysql.com/cluster>.
- The MySQL Cluster Forum: <http://forums.mysql.com/list.php?25>.
- Many MySQL Cluster users and some of the MySQL Cluster developers blog about their experiences with Cluster, and make feeds of these available through [PlanetMySQL](#)

[<http://www.planetmysql.org/>].

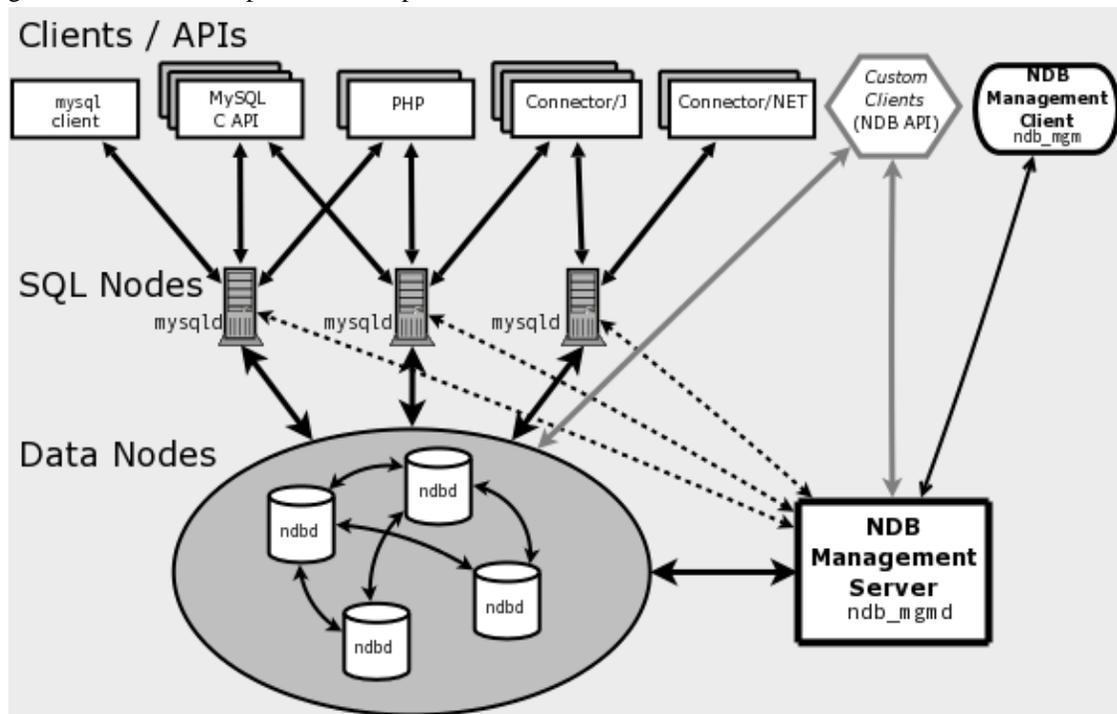

- If you are new to MySQL Cluster, you may find our Developer Zone article [How to set up a MySQL Cluster for two servers](http://dev.mysql.com/tech-resources/articles/mysql-cluster-for-two-servers.html) [<http://dev.mysql.com/tech-resources/articles/mysql-cluster-for-two-servers.html>] to be helpful.

15.1. MySQL Cluster Overview

MySQL Cluster is a technology that enables clustering of in-memory databases in a shared-nothing system. The shared-nothing architecture allows the system to work with very inexpensive hardware, and without any specific requirements on hardware or software. It also does not have any single point of failure because each component has its own memory and disk.

MySQL Cluster integrates the standard MySQL server with an in-memory clustered storage engine called **NDB**. In our documentation, the term **NDB** refers to the part of the setup that is specific to the storage engine, whereas “MySQL Cluster” refers to the combination of MySQL and the **NDB** storage engine.

A MySQL Cluster consists of a set of computers, each running a one or more processes which may include a MySQL server, a data node, a management server, and (possibly) a specialized data access programs. The relationship of these components in a cluster is shown here:

All these programs work together to form a MySQL Cluster. When data is stored in the **NDB Cluster** storage engine, the tables are stored in the data nodes. Such tables are directly accessible from all other MySQL servers in the cluster. Thus, in a payroll application storing data in a cluster, if one application updates the salary of an employee, all other MySQL servers that query this data can see this change immediately.

The data stored in the data nodes for MySQL Cluster can be mirrored; the cluster can handle failures of individual data nodes with no other impact than that a small number of transactions are aborted due to losing the transaction state. Because transactional applications are expected to handle transaction failure, this should not be a source of problems.

15.2. Basic MySQL Cluster Concepts

NDB is an in-memory storage engine offering high-availability and data-persistence features.

The *NDB* storage engine can be configured with a range of failover and load-balancing options, but it is easiest to start with the storage engine at the cluster level. MySQL Cluster's *NDB* storage engine contains a complete set of data, dependent only on other data within the cluster itself.

The cluster portion of MySQL Cluster is currently configured independently of the MySQL servers. In a MySQL Cluster, each part of the cluster is considered to be a *node*.

Note: In many contexts, the term “node” is used to indicate a computer, but when discussing MySQL Cluster it means a *process*. It is possible to run any number of nodes on a single computer, for which we use the term *cluster host*.

(However, it should be noted MySQL does not currently support the use of multiple data nodes on a single computer in a production setting. See [Issues exclusive to MySQL Cluster](#).)

There are three types of cluster nodes, and in a minimal MySQL Cluster configuration, there will be at least three nodes, one of each of these types:

- *Management node* (MGM node): The role of this type of node is to manage the other nodes within the MySQL Cluster, performing such functions as providing configuration data, starting and stopping nodes, running backup, and so forth. Because this node type manages the configuration of the other nodes, a node of this type should be started first, before any other node. An MGM node is started with the command `ndb_mgmd`.
- *Data node*: This type of node stores cluster data. There are as many data nodes as there are replicas, times the number of fragments. For example, with two replicas, each having two fragments, you will need four data nodes. It is not necessary to have more than one replica. A data node is started with the command `ndbd`.
- *SQL node*: This is a node that accesses the cluster data. In the case of MySQL Cluster, an SQL node is a traditional MySQL server that uses the *NDB Cluster* storage engine. An SQL node is typically started with the command `mysqld --ndbcluster` or by using `mysqld` with the `ndb-cluster` option added to `my.cnf`.

An SQL node is actually just a specialised type of *API node*, which designates any application which accesses Cluster data. One example of an API node is the `ndb_restore` utility that is used to restore a cluster backup. It is possible to write such applications using the *NDB API* [<http://dev.mysql.com/doc/en/ndbapi/>].

Important: It is not realistic to expect to employ a three-node setup in a production environment. Such a configuration provides no redundancy; in order to benefit from MySQL Cluster's high-availability features, you must use multiple data and SQL nodes. The use of multiple management nodes is also highly recommended.

For a brief introduction to the relationships between nodes, node groups, replicas, and partitions in MySQL Cluster, see [Section 15.2.1, “MySQL Cluster Nodes, Node Groups, Replicas, and Partitions”](#).

Configuration of a cluster involves configuring each individual node in the cluster and setting up individual communication links between nodes. MySQL Cluster is currently designed with the intention that data nodes are homogeneous in terms of processor power, memory space, and bandwidth. In addition, to provide a single point of configuration, all configuration data for the cluster as a whole is located in one configuration file.

The management server (MGM node) manages the cluster configuration file and the cluster log. Each

node in the cluster retrieves the configuration data from the management server, and so requires a way to determine where the management server resides. When interesting events occur in the data nodes, the nodes transfer information about these events to the management server, which then writes the information to the cluster log.

In addition, there can be any number of cluster client processes or applications. These are of two types:

- **Standard MySQL clients:** These are no different for MySQL Cluster than they are for standard (non-Cluster) MySQL. In other words, MySQL Cluster can be accessed from existing MySQL applications written in PHP, Perl, C, C++, Java, Python, Ruby, and so on.
- **Management clients:** These clients connect to the management server and provide commands for starting and stopping nodes gracefully, starting and stopping message tracing (debug versions only), showing node versions and status, starting and stopping backups, and so on.

15.2.1. MySQL Cluster Nodes, Node Groups, Replicas, and Partitions

This section discusses the manner in which MySQL Cluster divides and duplicates data for storage.

Central to an understanding of this topic are the following concepts, listed here with brief definitions:

- **(Data) Node:** An `ndbd` process, which stores a *replica*—that is, a copy of the *partition* (see below) assigned to the node group of which the node is a member.

Each data node should be located on a separate computer. While it is also possible to host multiple `ndbd` processes on a single computer, such a configuration is not supported.

It is common for the terms “node” and “data node” to be used interchangeably when referring to an `ndbd` process; where mentioned, management (MGM) nodes (`ndb_mgmd` processes) and SQL nodes (`mysqld` processes) are specified as such in this discussion.

- **Node Group:** A node group consists of one or more nodes, and stores partitions, or sets of *replicas* (see next item).

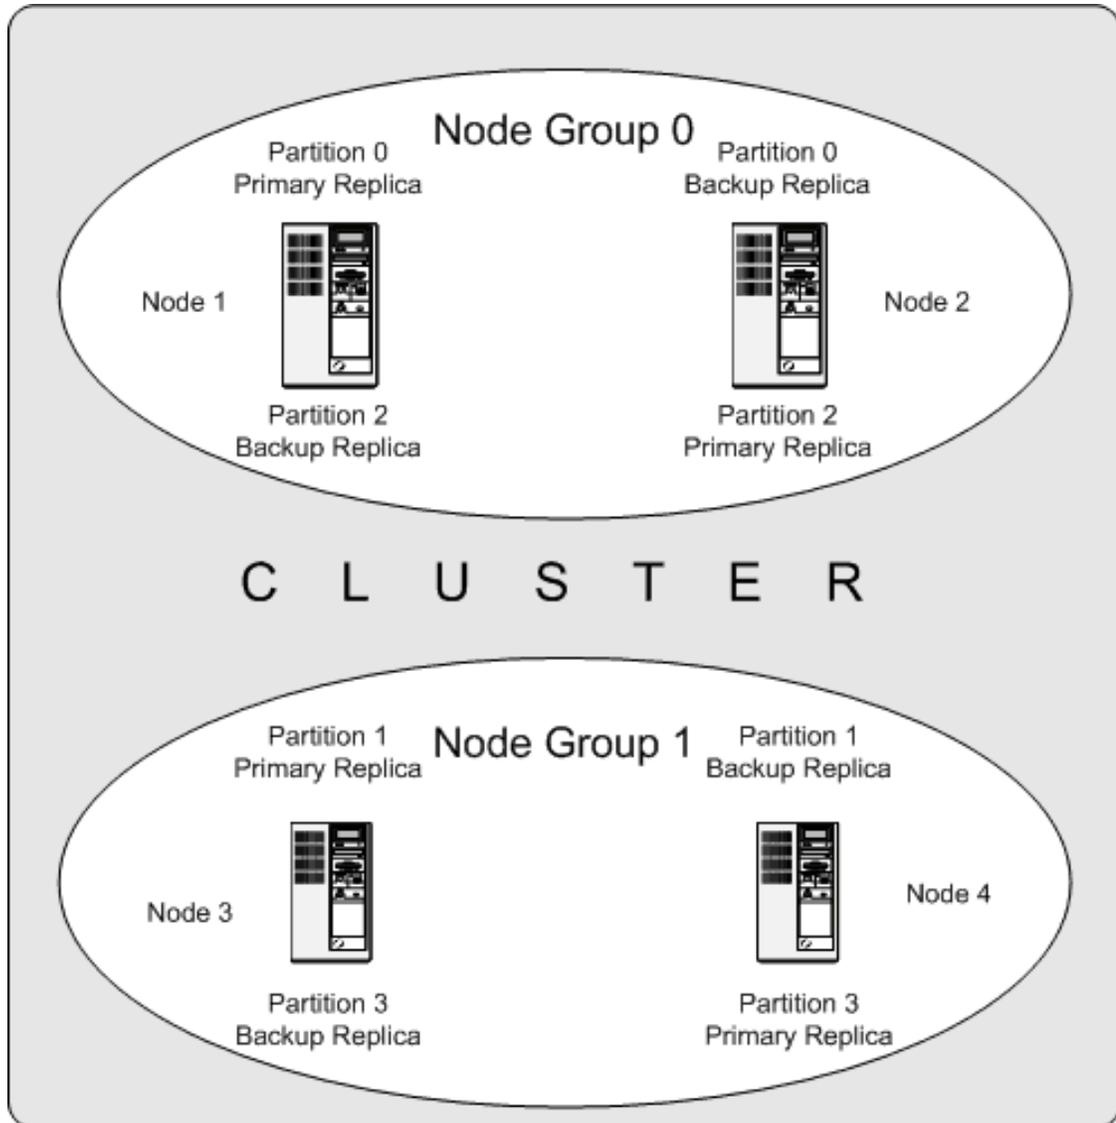

Note: Currently, all node groups in a cluster must have the same number of nodes.

- **Partition:** This is a portion of the data stored by the cluster. There are as many cluster partitions as nodes participating in the cluster. Each node is responsible for keeping at least one copy of any partitions assigned to it (that is, at least one replica) available to the cluster.

A replica belongs entirely to a single node; a node can (and usually does) store several replicas.

- **Replica:** This is a copy of a cluster partition. Each node in a node group stores a replica. Also sometimes known as a *partition replica*. The number of replicas is equal to the number of nodes per node group.

The following diagram illustrates a MySQL Cluster with four data nodes, arranged in two node groups of two nodes each; nodes 1 and 2 belong to node group 0, and nodes 3 and 4 belong to node group 1. Note that only data (`ndbd`) nodes are shown here; although a working cluster requires an `ndb_mgm` process for cluster management and at least one SQL node to access the data stored by the cluster, these have been omitted in the figure for clarity.

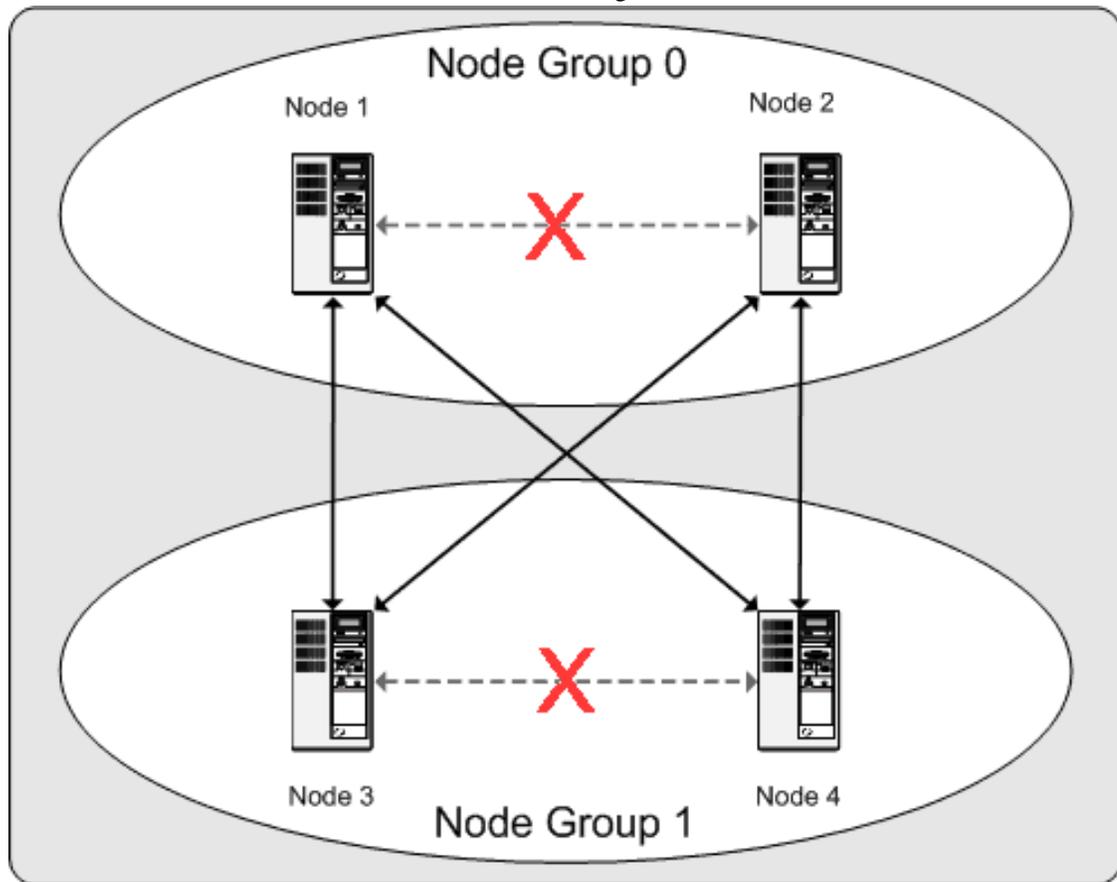

The data stored by the cluster is divided into four partitions, numbered 0, 1, 2, and 3. Each partition is stored — in multiple copies — on the same node group. Partitions are stored on alternate node groups:

- Partition 0 is stored on node group 0; a *primary replica* (primary copy) is stored on node 1, and a *backup replica* (backup copy of the partition) is stored on node 2.
- Partition 1 is stored on the other node group (node group 1); this partition's primary replica is on node 3, and its backup replica is on node 4.
- Partition 2 is stored on node group 0. However, the placing of its two replicas is reversed from that of Partition 0; for Partition 2, the primary replica is stored on node 2, and the backup on node 1.
- Partition 3 is stored on node group 1, and the placement of its two replicas are reversed from those of partition 1. That is, its primary replica is located on node 4, with the backup on node 3.

What this means regarding the continued operation of a MySQL Cluster is this: so long as each node group participating in the cluster has at least one node operating, the cluster has a complete copy of all

data and remains viable. This is illustrated in the next diagram.

In this example, where the cluster consists of two node groups of two nodes each, any combination of at least one node in node group 0 and at least one node in node group 1 is sufficient to keep the cluster “alive” (indicated by arrows in the diagram). However, if *both* nodes from *either* node group fail, the remaining two nodes are not sufficient (shown by the arrows marked out with an **X**); in either case, the cluster has lost an entire partition and so can no longer provide access to a complete set of all cluster data.

15.3. Simple Multi-Computer How-To

This section is a “How-To” that describes the basics for how to plan, install, configure, and run a MySQL Cluster. Whereas the examples in [Section 15.4, “MySQL Cluster Configuration”](#) provide more in-depth information on a variety of clustering options and configuration, the result of following the guidelines and procedures outlined here should be a usable MySQL Cluster which meets the *minimum* requirements for availability and safeguarding of data.

This section covers hardware and software requirements; networking issues; installation of MySQL Cluster; configuration issues; starting, stopping, and restarting the cluster; loading of a sample database; and performing queries.

Basic Assumptions

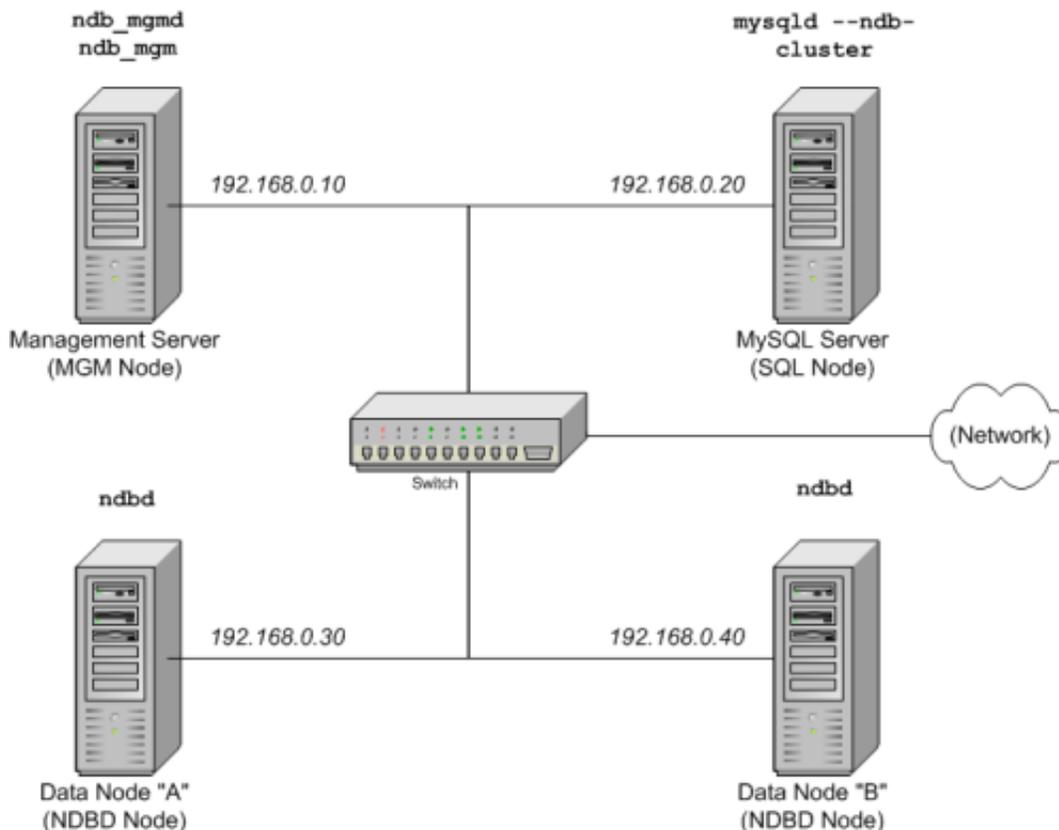

This How-To makes the following assumptions:

1. The cluster setup has four nodes, each on a separate host, and each with a fixed network address on

a typical Ethernet as shown here:

Node	IP Address
Management (MGM) node	192.168.0.10
MySQL server (SQL) node	192.168.0.20
Data (NDBD) node "A"	192.168.0.30
Data (NDBD) node "B"	192.168.0.40

This may be made clearer in the following diagram:

Note: In the interest of simplicity (and reliability), this How-To uses only numeric IP addresses. However, if DNS resolution is available on your network, it is possible to use hostnames in lieu of IP addresses in configuring Cluster. Alternatively, you can use the `/etc/hosts` file or your operating system's equivalent for providing a means to do host lookup if such is available.

- Each host in our scenario is an Intel-based desktop PC running a common, generic Linux distribution installed to disk in a standard configuration, and running no unnecessary services. The core OS with standard TCP/IP networking capabilities should be sufficient. Also for the sake of simplicity, we also assume that the filesystems on all hosts are set up identically. In the event that they are not, you will need to adapt these instructions accordingly.
- Standard 100 Mbps or 1 gigabit Ethernet cards are installed on each machine, along with the proper drivers for the cards, and that all four hosts are connected via a standard-issue Ethernet networking appliance such as a switch. (All machines should use network cards with the same throughput. That is, all four machines in the cluster should have 100 Mbps cards *or* all four machines should have 1 Gbps cards.) MySQL Cluster will work in a 100 Mbps network; however, gigabit Ethernet will

provide better performance.

Note that MySQL Cluster is *not* intended for use in a network for which throughput is less than 100 Mbps. For this reason (among others), attempting to run a MySQL Cluster over a public network such as the Internet is not likely to be successful, and is not recommended.

4. For our sample data, we will use the `world` database which is available for download from the MySQL AB Web site. As this database takes up a relatively small amount of space, we assume that each machine has 256MB RAM, which should be sufficient for running the operating system, host NDB process, and (for the data nodes) for storing the database.

Although we refer to a Linux operating system in this How-To, the instructions and procedures that we provide here should be easily adaptable to other supported operating systems. We also assume that you already know how to perform a minimal installation and configuration of the operating system with networking capability, or that you are able to obtain assistance in this elsewhere if needed.

We discuss MySQL Cluster hardware, software, and networking requirements in somewhat greater detail in the next section. (See [Section 15.3.1, “Hardware, Software, and Networking”](#).)

15.3.1. Hardware, Software, and Networking

One of the strengths of MySQL Cluster is that it can be run on commodity hardware and has no unusual requirements in this regard, other than for large amounts of RAM, due to the fact that all live data storage is done in memory. (Note that this is subject to change, and that we intend to implement disk-based storage in a future MySQL Cluster release.) Naturally, multiple and faster CPUs will enhance performance. Memory requirements for Cluster processes are relatively small.

The software requirements for Cluster are also modest. Host operating systems do not require any unusual modules, services, applications, or configuration to support MySQL Cluster. For supported operating systems, a standard installation should be sufficient. The MySQL software requirements are simple: all that is needed is a production release of MySQL 5.1 to have Cluster support. It is not necessary to compile MySQL yourself merely to be able to use Cluster. In this How-To, we assume that you are using the server binary appropriate to your operating system, available via the MySQL software downloads page at <http://dev.mysql.com/downloads/>.

For inter-node communication, Cluster supports TCP/IP networking in any standard topology, and the minimum expected for each host is a standard 100 Mbps Ethernet card, plus a switch, hub, or router to provide network connectivity for the cluster as a whole. We strongly recommend that a MySQL Cluster be run on its own subnet which is not shared with non-Cluster machines for the following reasons:

- **Security:** Communications between Cluster nodes are not encrypted or shielded in any way. The only means of protecting transmissions within a MySQL Cluster is to run your Cluster on a protected network. If you intend to use MySQL Cluster for Web applications, the cluster should definitely reside behind your firewall and not in your network's De-Militarized Zone ([DMZ](#) [http://compnetworking.about.com/cs/networksecurity/g/bldef_dmz.htm]) or elsewhere.
- **Efficiency:** Setting up a MySQL Cluster on a private or protected network allows the cluster to make exclusive use of bandwidth between cluster hosts. Using a separate switch for your MySQL Cluster not only helps protect against unauthorized access to Cluster data, it also ensures that Cluster nodes are shielded from interference caused by transmissions between other computers on the network. For enhanced reliability, you can use dual switches and dual cards to remove the network as a single point of failure; many device drivers support failover for such communication links.

It is also possible to use the high-speed Scalable Coherent Interface (SCI) with MySQL Cluster, but this is not a requirement. See [Section 15.12, “Using High-Speed Interconnects with MySQL Cluster”](#), for

more about this protocol and its use with MySQL Cluster.

15.3.2. Multi-Computer Installation

Each MySQL Cluster host computer running data or SQL nodes must have installed on it a MySQL server binary. For management nodes, it is not necessary to install the MySQL server binary, but you do have to install the MGM server daemon and client binaries (`ndb_mgmd` and `ndb_mgm`, respectively). This section covers the steps necessary to install the correct binaries for each type of Cluster node.

MySQL AB provides precompiled binaries that support Cluster, and there is generally no need to compile these yourself. Therefore, the first step in the installation process for each cluster host is to download the file `mysql-5.1.12-beta-pc-linux-gnu-i686.tar.gz` from the [MySQL downloads area](http://dev.mysql.com/downloads/) [http://dev.mysql.com/downloads/]. We assume that you have placed it in each machine's `/var/tmp` directory. (If you do require a custom binary, see [Section 2.9.3, “Installing from the Development Source Tree”](#).)

RPMs are also available for both 32-bit and 64-bit Linux platforms. (See [Section 2.4, “Installing MySQL on Linux”](#), for more information about installing MySQL using the RPMs.) After installing from RPM, you will still need to configure the cluster as discussed in [Section 15.3.3, “Multi-Computer Configuration”](#).

Note: After completing the installation, do not yet start any of the binaries. We will show you how to do so following the configuration of all nodes.

Storage and SQL Node Installation

On each of the three machines designated to host storage or SQL nodes, perform the following steps as the system `root` user:

1. Check your `/etc/passwd` and `/etc/group` files (or use whatever tools are provided by your operating system for managing users and groups) to see whether there is already a `mysql` group and `mysql` user on the system. Some OS distributions create these as part of the operating system installation process. If they are not already present, create a new `mysql` user group, and then add a `mysql` user to this group:

```
shell> groupadd mysql
shell> useradd -g mysql mysql
```

The syntax for `useradd` and `groupadd` may differ slightly on different versions of Unix, or they may have different names such as `adduser` and `addgroup`.

2. Change location to the directory containing the downloaded file, unpack the archive, and create a symlink to the `mysql` directory. Note that the actual file and directory names will vary according to the MySQL version number.

```
shell> cd /var/tmp
shell> tar -xvzf -C /usr/local mysql-5.1.12-beta-pc-linux-gnu-i686.tar.gz
shell> ln -s /usr/local/mysql-5.1.12-beta-pc-linux-gnu-i686 /usr/local/mysql
```

3. Change location to the `mysql` directory and run the supplied script for creating the system databases:

```
shell> cd mysql
shell> scripts/mysql_install_db --user=mysql
```

4. Set the necessary permissions for the MySQL server and data directories:

```
shell> chown -R root .
shell> chown -R mysql data
```

```
shell> chgrp -R mysql .
```

Note that the data directory on each machine hosting a data node is `/usr/local/mysql/data`. We will use this piece of information when we configure the management node. (See [Section 15.3.3, “Multi-Computer Configuration”](#).)

5. Copy the MySQL startup script to the appropriate directory, make it executable, and set it to start when the operating system is booted up:

```
shell> cp support-files/mysql.server /etc/rc.d/init.d/
shell> chmod +x /etc/rc.d/init.d/mysql.server
shell> chkconfig --add mysql.server
```

(The startup scripts directory may vary depending on your operating system and version — for example, in some Linux distributions, it is `/etc/init.d`.)

Here we use Red Hat's `chkconfig` for creating links to the startup scripts; use whatever means is appropriate for this purpose on your operating system and distribution, such as `update-rc.d` on Debian.

Remember that the preceding steps must be performed separately for each machine on which a storage or SQL node is to reside.

Management Node Installation

Installation for the management (MGM) node does not require installation of the `mysqld` binary. Only the binaries for the MGM server and client are required, which can be found in the downloaded archive. Again, we assume that you have placed this file in `/var/tmp`.

As system `root` (that is, after using `sudo`, `su root`, or your system's equivalent for temporarily assuming the system administrator account's privileges), perform the following steps to install `ndb_mgmd` and `ndb_mgm` on the Cluster management node host:

1. Change location to the `/var/tmp` directory, and extract the `ndb_mgm` and `ndb_mgmd` from the archive into a suitable directory such as `/usr/local/bin`:

```
shell> cd /var/tmp
shell> tar -zxvf mysql-5.1.12-beta-pc-linux-gnu-i686.tar.gz
shell> cd mysql-5.1.12-beta-pc-linux-gnu-i686
shell> cp /bin/ndb_mgm* /usr/local/bin
```

(You can safely delete the directory created by unpacking the downloaded archive, and the files it contains, from `/var/tmp` once `ndb_mgm` and `ndb_mgmd` have been copied to the executables directory.)

2. Change location to the directory into which you copied the files, and then make both of them executable:

```
shell> cd /usr/local/bin
shell> chmod +x ndb_mgm*
```

In [Section 15.3.3, “Multi-Computer Configuration”](#), we will create and write configuration files for all of the nodes in our example Cluster.

15.3.3. Multi-Computer Configuration

For our four-node, four-host MySQL Cluster, we will need to write four configuration files, one per node/host.

- Each data node or SQL node requires a `my.cnf` file that provides two pieces of information: a **connectstring** telling the node where to find the MGM node, and a line telling the MySQL server on this host (the machine hosting the data node) to run in NDB mode.

For more information on connectstrings, see [Section 15.4.4.2, “The Cluster connectstring”](#).

- The management node needs a `config.ini` file telling it how many replicas to maintain, how much memory to allocate for data and indexes on each data node, where to find the data nodes, where to save data to disk on each data node, and where to find any SQL nodes.

Configuring the Storage and SQL Nodes

The `my.cnf` file needed for the data nodes is fairly simple. The configuration file should be located in the `/etc` directory and can be edited using any text editor. (Create the file if it does not exist.) For example:

```
shell> vi /etc/my.cnf
```

We show `vi` being used here to create the file, but any text editor should work just as well.

For each data node and SQL node in our example setup, `my.cnf` should look like this:

```
# Options for mysqld process:
[MYSQLD]
ndbcluster                # run NDB engine
ndb-connectstring=192.168.0.10 # location of MGM node

# Options for ndbd process:
[MYSQL_CLUSTER]
ndb-connectstring=192.168.0.10 # location of MGM node
```

After entering the preceding information, save this file and exit the text editor. Do this for the machines hosting data node “A”, data node “B”, and the SQL node.

Important: Once you have started a `mysqld` process with the `ndbcluster` and `ndb-connectstring` parameters in the `[MYSQLD]` in the `my.cnf` file as shown previously, you cannot execute any `CREATE TABLE` or `ALTER TABLE` statements without having actually started the cluster. Otherwise, these statements will fail with an error. *This is by design.*

Configuring the Management Node

The first step in configuring the MGM node is to create the directory in which the configuration file can be found and then to create the file itself. For example (running as `root`):

```
shell> mkdir /var/lib/mysql-cluster
shell> cd /var/lib/mysql-cluster
shell> vi config.ini
```

For our representative setup, the `config.ini` file should read as follows:

```
# Options affecting ndbd processes on all data nodes:
[NDBD DEFAULT]
NoOfReplicas=2      # Number of replicas
DataMemory=80M     # How much memory to allocate for data storage
IndexMemory=18M    # How much memory to allocate for index storage
                   # For DataMemory and IndexMemory, we have used the
                   # default values. Since the "world" database takes up
                   # only about 500KB, this should be more than enough for
```

```

# this example Cluster setup.

# TCP/IP options:
[TCP DEFAULT]
portnumber=2202 # This the default; however, you can use any
                # port that is free for all the hosts in cluster
                # Note: It is recommended beginning with MySQL 5.0 that
                # you do not specify the portnumber at all and simply allow
                # the default value to be used instead

# Management process options:
[NDB_MGMD]
hostname=192.168.0.10 # Hostname or IP address of MGM node
datadir=/var/lib/mysql-cluster # Directory for MGM node logfiles

# Options for data node "A":
[NDBD]
# (one [NDBD] section per data node)
hostname=192.168.0.30 # Hostname or IP address
datadir=/usr/local/mysql/data # Directory for this data node's datafiles

# Options for data node "B":
[NDBD]
hostname=192.168.0.40 # Hostname or IP address
datadir=/usr/local/mysql/data # Directory for this data node's datafiles

# SQL node options:
[MYSQLD]
hostname=192.168.0.20 # Hostname or IP address
# (additional mysqld connections can be
# specified for this node for various
# purposes such as running ndb_restore)

```

(**Note:** The `world` database can be downloaded from <http://dev.mysql.com/doc/>, where it can be found listed under “Examples.”)

After all the configuration files have been created and these minimal options have been specified, you are ready to proceed with starting the cluster and verifying that all processes are running. We discuss how this is done in [Section 15.3.4, “Initial Startup”](#).

For more detailed information about the available MySQL Cluster configuration parameters and their uses, see [Section 15.4.4, “Configuration File”](#), and [Section 15.4, “MySQL Cluster Configuration”](#). For configuration of MySQL Cluster as relates to making backups, see [Section 15.8.4, “Configuration for Cluster Backup”](#).

Note: The default port for Cluster management nodes is 1186; the default port for data nodes is 2202. Beginning with MySQL 5.0.3, this restriction is lifted, and the cluster automatically allocates ports for data nodes from those that are already free.

15.3.4. Initial Startup

Starting the cluster is not very difficult after it has been configured. Each cluster node process must be started separately, and on the host where it resides. Although it is possible to start the nodes in any order, it is recommended that the management node be started first, followed by the storage nodes, and then finally by any SQL nodes:

1. On the management host, issue the following command from the system shell to start the MGM node process:

```
shell> ndb_mgmd -f /var/lib/mysql-cluster/config.ini
```

Note that `ndb_mgmd` must be told where to find its configuration file, using the `-f` or `-config-file` option. (See [Section 15.6.3, “ndb_mgmd, the Management Server Process”](#), for details.)

2. On each of the data node hosts, run this command to start the `ndbd` process for the first time:

```
shell> ndbd --initial
```

Note that it is very important to use the `--initial` parameter *only* when starting `ndbd` for the first time, or when restarting after a backup/restore operation or a configuration change. This is because the `--initial` option causes the node to delete any files created by earlier `ndbd` instances that are needed for recovery, including the recovery log files.

An exception to this is that `--initial` does not delete Disk Data files. If you do need to perform an initial restart of the cluster, you must delete any existing Disk Data logfiles and datafiles manually.

3. If you used RPM files to install MySQL on the cluster host where the SQL node is to reside, you can (and should) use the startup script installed in `/etc/init.d` to start the MySQL server process on the SQL node.

If all has gone well, and the cluster has been set up correctly, the cluster should now be operational. You can test this by invoking the `ndb_mgm` management node client. The output should look like that shown here, although you might see some slight differences in the output depending upon the exact version of MySQL that you are using:

```
shell> ndb_mgm
-- NDB Cluster -- Management Client --
ndb_mgm> SHOW
Connected to Management Server at: localhost:1186
Cluster Configuration
-----
[ndbd(NDB)]      2 node(s)
id=2      @192.168.0.30 (Version: 5.1.12-beta, Nodegroup: 0, Master)
id=3      @192.168.0.40 (Version: 5.1.12-beta, Nodegroup: 0)

[ndb_mgmd(MGM)] 1 node(s)
id=1      @192.168.0.10 (Version: 5.1.12-beta)

[mysqld(SQL)]   1 node(s)
id=4      (Version: 5.1.12-beta)
```

Note: The SQL node is referenced here as `[mysqld(API)]`. This is perfectly normal, and reflects the fact that the `mysqld` process is acting as a cluster API node.

You should now be ready to work with databases, tables, and data in MySQL Cluster. See [Section 15.3.5, “Loading Sample Data and Performing Queries”](#), for a brief discussion.

15.3.5. Loading Sample Data and Performing Queries

Working with data in MySQL Cluster is not much different from doing so in MySQL without Cluster. There are two points to keep in mind:

- For a table to be replicated in the cluster, it must use the `NDB Cluster` storage engine. To specify this, use the `ENGINE=NDB` or `ENGINE=NDBCLUSTER` table option. You can add this option when creating the table:

```
CREATE TABLE tbl_name ( ... ) ENGINE=NDBCLUSTER;
```

Alternatively, for an existing table that uses a different storage engine, use `ALTER TABLE` to change the table to use `NDB Cluster`:

```
ALTER TABLE tbl_name ENGINE=NDBCLUSTER;
```

- Each NDB table *must* have a primary key. If no primary key is defined by the user when a table is created, the NDB Cluster storage engine automatically generates a hidden one. (Note: This hidden key takes up space just as does any other table index. It is not uncommon to encounter problems due to insufficient memory for accommodating these automatically created indexes.)

If you are importing tables from an existing database using the output of `mysqldump`, you can open the SQL script in a text editor and add the `ENGINE` option to any table creation statements, or replace any existing `ENGINE` (or `TYPE`) options. Suppose that you have the `world` sample database on another MySQL server that does not support MySQL Cluster, and you want to export the `City` table:

```
shell> mysqldump --add-drop-table world City > city_table.sql
```

The resulting `city_table.sql` file will contain this table creation statement (and the `INSERT` statements necessary to import the table data):

```
DROP TABLE IF EXISTS `City`;
CREATE TABLE `City` (
  `ID` int(11) NOT NULL auto_increment,
  `Name` char(35) NOT NULL default '',
  `CountryCode` char(3) NOT NULL default '',
  `District` char(20) NOT NULL default '',
  `Population` int(11) NOT NULL default '0',
  PRIMARY KEY (`ID`)
) ENGINE=MyISAM DEFAULT CHARSET=latin1;

INSERT INTO `City` VALUES (1,'Kabul','AFG','Kabol',1780000);
INSERT INTO `City` VALUES (2,'Qandahar','AFG','Qandahar',237500);
INSERT INTO `City` VALUES (3,'Herat','AFG','Herat',186800);
(remaining INSERT statements omitted)
```

You will need to make sure that MySQL uses the NDB storage engine for this table. There are two ways that this can be accomplished. One of these is to modify the table definition *before* importing it into the Cluster database. Using the `City` table as an example, modify the `ENGINE` option of the definition as follows:

```
DROP TABLE IF EXISTS `City`;
CREATE TABLE `City` (
  `ID` int(11) NOT NULL auto_increment,
  `Name` char(35) NOT NULL default '',
  `CountryCode` char(3) NOT NULL default '',
  `District` char(20) NOT NULL default '',
  `Population` int(11) NOT NULL default '0',
  PRIMARY KEY (`ID`)
) ENGINE=NDBCLUSTER DEFAULT CHARSET=latin1;

INSERT INTO `City` VALUES (1,'Kabul','AFG','Kabol',1780000);
INSERT INTO `City` VALUES (2,'Qandahar','AFG','Qandahar',237500);
INSERT INTO `City` VALUES (3,'Herat','AFG','Herat',186800);
(remaining INSERT statements omitted)
```

This must be done for the definition of each table that is to be part of the clustered database. The easiest way to accomplish this is to do a search-and-replace on the file that contains the definitions and replace all instances of `TYPE=engine_name` or `ENGINE=engine_name` with `ENGINE=NDBCLUSTER`. If you do not want to modify the file, you can use the unmodified file to create the tables, and then use `ALTER TABLE` to change their storage engine. The particulars are given later in this section.

Assuming that you have already created a database named `world` on the SQL node of the cluster, you can then use the `mysql` command-line client to read `city_table.sql`, and create and populate the corresponding table in the usual manner:

```
shell> mysql world < city_table.sql
```

It is very important to keep in mind that the preceding command must be executed on the host where the

SQL node is running (in this case, on the machine with the IP address 192.168.0.20).

To create a copy of the entire `world` database on the SQL node, use `mysqldump` on the non-cluster server to export the database to a file named `world.sql`; for example, in the `/tmp` directory. Then modify the table definitions as just described and import the file into the SQL node of the cluster like this:

```
shell> mysql world < /tmp/world.sql
```

If you save the file to a different location, adjust the preceding instructions accordingly.

It is important to note that `NDB Cluster` in MySQL 5.1 does not support autodiscovery of databases. (See [Section 15.13, “Known Limitations of MySQL Cluster”](#).) This means that, once the `world` database and its tables have been created on one data node, you need to issue the `CREATE SCHEMA world` statement.

Running `SELECT` queries on the SQL node is no different from running them on any other instance of a MySQL server. To run queries from the command line, you first need to log in to the MySQL Monitor in the usual way (specify the `root` password at the `Enter password:` prompt):

```
shell> mysql -u root -p
Enter password:
Welcome to the MySQL monitor.  Commands end with ; or \g.
Your MySQL connection id is 1 to server version: 5.1.12-beta

Type 'help;' or '\h' for help. Type '\c' to clear the buffer.

mysql>
```

We simply use the MySQL server's `root` account and assume that you have followed the standard security precautions for installing a MySQL server, including setting a strong `root` password. For more information, see [Section 2.10.3, “Securing the Initial MySQL Accounts”](#).

It is worth taking into account that Cluster nodes do not make use of the MySQL privilege system when accessing one another. Setting or changing MySQL user accounts (including the `root` account) effects only applications that access the SQL node, not interaction between nodes.

If you did not modify the `ENGINE` clauses in the table definitions prior to importing the SQL script, you should run the following statements at this point:

```
mysql> USE world;
mysql> ALTER TABLE City ENGINE=NDBCLUSTER;
mysql> ALTER TABLE Country ENGINE=NDBCLUSTER;
mysql> ALTER TABLE CountryLanguage ENGINE=NDBCLUSTER;
```

Selecting a database and running a `SELECT` query against a table in that database is also accomplished in the usual manner, as is exiting the MySQL Monitor:

```
mysql> USE world;
mysql> SELECT Name, Population FROM City ORDER BY Population DESC LIMIT 5;
+-----+-----+
| Name      | Population |
+-----+-----+
| Bombay    | 10500000  |
| Seoul     | 9981619   |
| São Paulo | 9968485   |
| Shanghai  | 9696300   |
| Jakarta   | 9604900   |
+-----+-----+
5 rows in set (0.34 sec)

mysql> \q
Bye
shell>
```

Applications that use MySQL can employ standard APIs to access NDB tables. It is important to remember that your application must access the SQL node, and not the MGM or data nodes. This brief example shows how we might execute the `SELECT` statement just shown by using PHP 5's `mysqli` extension running on a Web server elsewhere on the network:

```
<!DOCTYPE HTML PUBLIC "-//W3C//DTD HTML 4.01 Transitional//EN"
"http://www.w3.org/TR/html4/loose.dtd">
<html>
<head>
  <meta http-equiv="Content-Type"
        content="text/html; charset=iso-8859-1">
  <title>SIMPLE mysqli SELECT</title>
</head>
<body>
<?php
  # connect to SQL node:
  $link = new mysqli('192.168.0.20', 'root', 'root_password', 'world');
  # parameters for mysqli constructor are:
  #   host, user, password, database

  if( mysqli_connect_errno() )
    die("Connect failed: " . mysqli_connect_error());

  $query = "SELECT Name, Population
           FROM City
           ORDER BY Population DESC
           LIMIT 5";

  # if no errors...
  if( $result = $link->query($query) )
  {
?>
<table border="1" width="40%" cellpadding="4" cellspacing="1">
  <tbody>
    <tr>
      <th width="10%">City</th>
      <th>Population</th>
    </tr>
  <?
    # then display the results...
    while($row = $result->fetch_object())
      printf("<tr>\n  <td align=\"center\">%s</td><td>%d</td>\n</tr>\n",
            $row->Name, $row->Population);
  ?>
  </tbody>
</table>
<?
  # ...and verify the number of rows that were retrieved
  printf("<p>Affected rows: %d</p>\n", $link->affected_rows);
  }
  else
    # otherwise, tell us what went wrong
    echo mysqli_error();

  # free the result set and the mysqli connection object
  $result->close();
  $link->close();
?>
</body>
</html>
```

We assume that the process running on the Web server can reach the IP address of the SQL node.

In a similar fashion, you can use the MySQL C API, Perl-DBI, Python-mysql, or MySQL AB's own Connectors to perform the tasks of data definition and manipulation just as you would normally with MySQL.

15.3.6. Safe Shutdown and Restart

To shut down the cluster, enter the following command in a shell on the machine hosting the MGM node:

```
shell> ndb_mgm -e shutdown
```

The `-e` option here is used to pass a command to the `ndb_mgm` client from the shell. See [Section 4.3.1, “Using Options on the Command Line”](#). The command causes the `ndb_mgm`, `ndb_mgmd`, and any `ndbd` processes to terminate gracefully. Any SQL nodes can be terminated using `mysqladmin shutdown` and other means.

To restart the cluster, run these commands:

- On the management host (192.168.0.10 in our example setup):

```
shell> ndb_mgmd -f /var/lib/mysql-cluster/config.ini
```

- On each of the data node hosts (192.168.0.30 and 192.168.0.40):

```
shell> ndbd
```

Remember *not* to invoke this command with the `--initial` option when restarting an NDBD node normally.

- On the SQL host (192.168.0.20):

```
shell> mysqld &
```

For information on making Cluster backups, see [Section 15.8.2, “Using The Management Client to Create a Backup”](#).

To restore the cluster from backup requires the use of the `ndb_restore` command. This is covered in [Section 15.8.3, “How to Restore a Cluster Backup”](#).

More information on configuring MySQL Cluster can be found in [Section 15.4, “MySQL Cluster Configuration”](#).

15.4. MySQL Cluster Configuration

A MySQL server that is part of a MySQL Cluster differs in only one respect from a normal (non-clustered) MySQL server, in that it employs the **NDB Cluster** storage engine. This engine is also referred to simply as **NDB**, and the two forms of the name are synonymous.

To avoid unnecessary allocation of resources, the server is configured by default with the **NDB** storage engine disabled. To enable **NDB**, you must modify the server's `my.cnf` configuration file, or start the server with the `--ndbcluster` option.

The MySQL server is a part of the cluster, so it also must know how to access an MGM node to obtain the cluster configuration data. The default behavior is to look for the MGM node on `localhost`. However, should you need to specify that its location is elsewhere, this can be done in `my.cnf` or on the MySQL server command line. Before the **NDB** storage engine can be used, at least one MGM node must be operational, as well as any desired data nodes.

15.4.1. Building MySQL Cluster from Source Code

NDB, the Cluster storage engine, is available in binary distributions for Linux, Mac OS X, and Solaris. We are working to make Cluster run on all operating systems supported by MySQL, including Windows.

If you choose to build from a source tarball or the MySQL 5.1 BitKeeper tree, be sure to use the `--with-ndbcluster` option when running `configure`. You can also use the `BUILD/compile-pentium-max` build script. Note that this script includes OpenSSL, so you must either have or obtain OpenSSL to build successfully, or else modify `compile-pentium-max` to exclude this requirement. Of course, you can also just follow the standard instructions for compiling your own binaries, and then perform the usual tests and installation procedure. See [Section 2.9.3, “Installing from the Development Source Tree”](#).

15.4.2. Installing the Software

In the next few sections, we assume that you are already familiar with installing MySQL, and here we cover only the differences between configuring MySQL Cluster and configuring MySQL without clustering. (See [Chapter 2, *Installing and Upgrading MySQL*](#), if you require more information about the latter.)

You will find Cluster configuration easiest if you have already have all management and data nodes running first; this is likely to be the most time-consuming part of the configuration. Editing the `my.cnf` file is fairly straightforward, and this section will cover only any differences from configuring MySQL without clustering.

15.4.3. Quick Test Setup of MySQL Cluster

To familiarize you with the basics, we will describe the simplest possible configuration for a functional MySQL Cluster. After this, you should be able to design your desired setup from the information provided in the other relevant sections of this chapter.

First, you need to create a configuration directory such as `/var/lib/mysql-cluster`, by executing the following command as the system `root` user:

```
shell> mkdir /var/lib/mysql-cluster
```

In this directory, create a file named `config.ini` that contains the following information. Substitute appropriate values for `HostName` and `DataDir` as necessary for your system.

```
# file "config.ini" - showing minimal setup consisting of 1 data node,
# 1 management server, and 3 MySQL servers.
# The empty default sections are not required, and are shown only for
# the sake of completeness.
# Data nodes must provide a hostname but MySQL Servers are not required
# to do so.
# If you don't know the hostname for your machine, use localhost.
# The DataDir parameter also has a default value, but it is recommended to
# set it explicitly.
# Note: DB, API, and MGM are aliases for NDBD, MYSQLD, and NDB_MGMD
# respectively. DB and API are deprecated and should not be used in new
# installations.
[NDBD DEFAULT]
NoOfReplicas= 1

[MYSQLD DEFAULT]
[NDB_MGMD DEFAULT]
[TCP DEFAULT]

[NDB_MGMD]
HostName= myhost.example.com

[NDBD]
HostName= myhost.example.com
DataDir= /var/lib/mysql-cluster

[MYSQLD]
[MYSQLD]
[MYSQLD]
```

You can now start the `ndb_mgmd` management server. By default, it attempts to read the `config.ini` file in its current working directory, so change location into the directory where the file is located and then invoke `ndb_mgmd`:

```
shell> cd /var/lib/mysql-cluster
shell> ndb_mgmd
```

Then start a single data node by running `ndbd`. When starting `ndbd` for a given data node for the very first time, you should use the `--initial` option as shown here:

```
shell> ndbd --initial
```

For subsequent `ndbd` starts, you will generally want to *omit* the `--initial` option:

```
shell> ndbd
```

The reason for omitting `--initial` on subsequent restarts is that this option causes `ndbd` to delete and re-create all existing data and log files (as well as all table metadata) for this data node. One exception to this rule about not using `--initial` except for the first `ndbd` invocation is that you use it when restarting the cluster and restoring from backup after adding new data nodes.

By default, `ndbd` looks for the management server at `localhost` on port 1186.

Note: If you have installed MySQL from a binary tarball, you will need to specify the path of the `ndb_mgmd` and `ndbd` servers explicitly. (Normally, these will be found in `/usr/local/mysql/bin`.)

Finally, change location to the MySQL data directory (usually `/var/lib/mysql` or `/usr/local/mysql/data`), and make sure that the `my.cnf` file contains the option necessary to enable the NDB storage engine:

```
[mysqld]
ndbcluster
```

You can now start the MySQL server as usual:

```
shell> mysqld_safe --user=mysql &
```

Wait a moment to make sure the MySQL server is running properly. If you see the notice `mysql ended`, check the server's `.err` file to find out what went wrong.

If all has gone well so far, you now can start using the cluster. Connect to the server and verify that the `NDBCLUSTER` storage engine is enabled:

```
shell> mysql
Welcome to the MySQL monitor.  Commands end with ; or \g.
Your MySQL connection id is 1 to server version: 5.1.12-beta-Max

Type 'help;' or '\h' for help. Type '\c' to clear the buffer.

mysql> SHOW ENGINES\G
...
***** 12. row *****
Engine: NDBCLUSTER
Support: YES
Comment: Clustered, fault-tolerant, memory-based tables
***** 13. row *****
Engine: NDB
Support: YES
Comment: Alias for NDBCLUSTER
...

```

The row numbers shown in the preceding example output may be different from those shown on your system, depending upon how your server is configured.

Try to create an `NDBCLUSTER` table:

```
shell> mysql
mysql> USE test;
Database changed

mysql> CREATE TABLE ctest (i INT) ENGINE=NDBCLUSTER;
Query OK, 0 rows affected (0.09 sec)

mysql> SHOW CREATE TABLE ctest \G
***** 1. row *****
      Table: ctest
Create Table: CREATE TABLE `ctest` (
  `i` int(11) default NULL
) ENGINE=ndbcluster DEFAULT CHARSET=latin1
1 row in set (0.00 sec)
```

To check that your nodes were set up properly, start the management client:

```
shell> ndb_mgm
```

Use the `SHOW` command from within the management client to obtain a report on the cluster's status:

```
NDB> SHOW
Cluster Configuration
-----
[ndbd(NDB)]      1 node(s)
id=2      @127.0.0.1 (Version: 3.5.3, Nodegroup: 0, Master)

[ndb_mgmd(MGM)] 1 node(s)
id=1      @127.0.0.1 (Version: 3.5.3)

[mysqld(API)]   3 node(s)
id=3      @127.0.0.1 (Version: 3.5.3)
id=4 (not connected, accepting connect from any host)
id=5 (not connected, accepting connect from any host)
```

At this point, you have successfully set up a working MySQL Cluster. You can now store data in the cluster by using any table created with `ENGINE=NDBCLUSTER` or its alias `ENGINE=NDB`.

15.4.4. Configuration File

Configuring MySQL Cluster requires working with two files:

- `my.cnf`: Specifies options for all MySQL Cluster executables. This file, with which you should be familiar with from previous work with MySQL, must be accessible by each executable running in the cluster.
- `config.ini`: This file is read only by the MySQL Cluster management server, which then distributes the information contained therein to all processes participating in the cluster. `config.ini` contains a description of each node involved in the cluster. This includes configuration parameters for data nodes and configuration parameters for connections between all nodes in the cluster. For a quick reference to the sections that can appear in this file, and what sorts of configuration parameters may be placed in each section, see [Sections of the config.ini File](#).

We are continuously making improvements in Cluster configuration and attempting to simplify this process. Although we strive to maintain backward compatibility, there may be times when introduce an incompatible change. In such cases we will try to let Cluster users know in advance if a change is not backward compatible. If you find such a change and we have not documented it, please report it in the

MySQL bugs database using the instructions given in [Section 1.8, “How to Report Bugs or Problems”](#).

15.4.4.1. Basic Example Configuration

To support MySQL Cluster, you will need to update `my.cnf` as shown in the following example. Note that the options shown here should not be confused with those that are used in `config.ini` files. You may also specify these parameters on the command line when invoking the executables.

```
# my.cnf
# example additions to my.cnf for MySQL Cluster
# (valid in MySQL 5.1)

# enable ndbcluster storage engine, and provide connectstring for
# management server host (default port is 1186)
[mysqld]
ndbcluster
ndb-connectstring=ndb_mgmd.mysql.com

# provide connectstring for management server host (default port: 1186)
[ndbd]
connect-string=ndb_mgmd.mysql.com

# provide connectstring for management server host (default port: 1186)
[ndb_mgm]
connect-string=ndb_mgmd.mysql.com

# provide location of cluster configuration file
[ndb_mgmd]
config-file=/etc/config.ini
```

(For more information on connectstrings, see [Section 15.4.4.2, “The Cluster connectstring”](#).)

```
# my.cnf
# example additions to my.cnf for MySQL Cluster
# (will work on all versions)

# enable ndbcluster storage engine, and provide connectstring for management
# server host to the default port 1186
[mysqld]
ndbcluster
ndb-connectstring=ndb_mgmd.mysql.com:1186
```

Important: Once you have started a `mysqld` process with the `ndbcluster` and `ndb-connectstring` parameters in the `[MYSQLD]` in the `my.cnf` file as shown previously, you cannot execute any `CREATE TABLE` or `ALTER TABLE` statements without having actually started the cluster. Otherwise, these statements will fail with an error. *This is by design.*

You may also use a separate `[mysql_cluster]` section in the cluster `my.cnf` file for settings to be read and used by all executables:

```
# cluster-specific settings
[mysql_cluster]
ndb-connectstring=ndb_mgmd.mysql.com:1186
```

For additional `NDB` variables that can be set in the `my.cnf` file, see [Section 5.2.3, “System Variables”](#).

The configuration file is named `config.ini` by default. It is read by `ndb_mgmd` at startup and can be placed anywhere. Its location and name are specified by using `--config-file=path_name` on the `ndb_mgmd` command line. If the configuration file is not specified, `ndb_mgmd` by default tries to read a file named `config.ini` located in the current working directory.

Currently, the configuration file is in INI format, which consists of sections preceded by section headings (surrounded by square brackets), followed by the appropriate parameter names and values. One deviation from the standard INI format is that the parameter name and value can be separated by a colon

:') as well as the equals sign ('='). Another deviation is that sections are not uniquely identified by section name. Instead, unique sections (such as two different nodes of the same type) are identified by a unique ID specified as a parameter within the section.

Default values are defined for most parameters, and can also be specified in `config.ini`. To create a default value section, simply add the word `DEFAULT` to the section name. For example, an `[NDBD]` section contains parameters that apply to a particular data node, whereas an `[NDBD DEFAULT]` section contains parameters that apply to all data nodes. Suppose that all data nodes should use the same data memory size. To configure them all, create an `[NDBD DEFAULT]` section that contains a `DataMemory` line to specify the data memory size.

At a minimum, the configuration file must define the computers and nodes involved in the cluster and on which computers these nodes are located. An example of a simple configuration file for a cluster consisting of one management server, two data nodes and two MySQL servers is shown here:

```
# file "config.ini" - 2 data nodes and 2 SQL nodes
# This file is placed in the startup directory of ndb_mgmd (the
# management server)
# The first MySQL Server can be started from any host. The second
# can be started only on the host mysqld_5.mysql.com

[NDBD DEFAULT]
NoOfReplicas= 2
DataDir= /var/lib/mysql-cluster

[NDB_MGMD]
Hostname= ndb_mgmd.mysql.com
DataDir= /var/lib/mysql-cluster

[NDBD]
HostName= ndbd_2.mysql.com

[NDBD]
HostName= ndbd_3.mysql.com

[MYSQLD]
[MYSQLD]
HostName= mysqld_5.mysql.com
```

Note that each node has its own section in the `config.ini`. For instance, this cluster has two data nodes, so the preceding configuration file contains two `[NDBD]` sections defining these nodes.

Sections of the `config.ini` File

There are six different sections that you can use in the `config.ini` configuration file, as described in the following list:

- `[COMPUTER]`: Defines cluster hosts. This is not required to configure a viable MySQL Cluster, but be may used as a convenience when setting up a large cluster. See [Section 15.4.4.3, “Defining Cluster Computers”](#), for more information.
- `[NDBD]`: Defines a cluster data node (`ndbd` process). See [Section 15.4.4.5, “Defining Data Nodes”](#), for details.
- `[MYSQLD]`: Defines the cluster's MySQL server nodes (also called SQL or API nodes). For a discussion of SQL node configuration, see [Section 15.4.4.6, “Defining SQL and Other API Nodes”](#).
- `[MGM]` or `[NDB_MGMD]`: Defines a cluster management server (MGM) node. For information concerning the configuration of MGM nodes, see [Section 15.4.4.4, “Defining the Management Server”](#).
- `[TCP]`: Defines a TCP/IP connection between cluster nodes, with TCP/IP being the default connection protocol. Normally, `[TCP]` or `[TCP DEFAULT]` sections are not required to set up a MySQL Cluster, as the cluster handles this automatically; however, it may be necessary in some situations to override the defaults provided by the cluster. See [Section 15.4.4.7, “Cluster TCP/IP Connections”](#),

for information about available TCP/IP configuration parameters and how to use them. (You may also find [Section 15.4.4.8, “TCP/IP Connections Using Direct Connections”](#) to be of interest in some cases.)

- [\[SHM \]](#): Defines shared-memory connections between nodes. In MySQL 5.1-max, it is enabled by default, but should still be considered experimental. For a discussion of SHM interconnects, see [Section 15.4.4.9, “Shared-Memory Connections”](#).
- [\[SCI \]](#): Defines *Scalable Coherent Interface* connections between cluster data nodes. Such connections require software which, while freely available, is not part of the MySQL Cluster distribution, as well as specialised hardware. See [Section 15.4.4.10, “SCI Transport Connections”](#) for detailed information about SCI interconnects.

You can define [DEFAULT](#) values for each section. All Cluster parameter names are case-insensitive, which differs from parameters specified in `my.cnf` or `my.ini` files.

15.4.4.2. The Cluster `connectstring`

With the exception of the MySQL Cluster management server (`ndb_mgmd`), each node that is part of a MySQL Cluster requires a *connectstring* that points to the management server's location. This connectstring is used in establishing a connection to the management server as well as in performing other tasks depending on the node's role in the cluster. The syntax for a connectstring is as follows:

```
<connectstring> :=
  [<nodeid-specification> , ]<host-specification> [ , <host-specification> ]
<nodeid-specification> := node_id
<host-specification> := host_name [:port_num]
```

`node_id` is an integer larger than 1 which identifies a node in `config.ini`. `host_name` is a string representing a valid Internet host name or IP address. `port_num` is an integer referring to a TCP/IP port number.

```
example 1 (long):    "nodeid=2,myhost1:1100,myhost2:1100,192.168.0.3:1200"
example 2 (short):  "myhost1"
```

All nodes will use `localhost:1186` as the default connectstring value if none is provided. If `port_num` is omitted from the connectstring, the default port is 1186. This port should always be available on the network because it has been assigned by IANA for this purpose (see <http://www.iana.org/assignments/port-numbers> for details).

By listing multiple `<host-specification>` values, it is possible to designate several redundant management servers. A cluster node will attempt to contact successive management servers on each host in the order specified, until a successful connection has been established.

There are a number of different ways to specify the connectstring:

- Each executable has its own command-line option which enables specifying the management server at startup. (See the documentation for the respective executable.)
- It is also possible to set the connectstring for all nodes in the cluster at once by placing it in a `[mysql_cluster]` section in the management server's `my.cnf` file.
- For backward compatibility, two other options are available, using the same syntax:
 1. Set the `NDB_CONNECTSTRING` environment variable to contain the connectstring.

2. Write the connectstring for each executable into a text file named `Ndb.cfg` and place this file in the executable's startup directory.

However, these are now deprecated and should not be used for new installations.

The recommended method for specifying the connectstring is to set it on the command line or in the `my.cnf` file for each executable.

15.4.4.3. Defining Cluster Computers

The `[COMPUTER]` section has no real significance other than serving as a way to avoid the need of defining host names for each node in the system. All parameters mentioned here are required.

- `Id`

This is an integer value, used to refer to the host computer elsewhere in the configuration file. This is not the same as the node ID.

- `HostName`

This is the computer's hostname or IP address.

15.4.4.4. Defining the Management Server

The `[NDB_MGMD]` section is used to configure the behavior of the management server. `[MGM]` can be used as an alias; the two section names are equivalent. All parameters in the following list are optional and assume their default values if omitted. **Note:** If neither the `ExecuteOnComputer` nor the `HostName` parameter is present, the default value `localhost` will be assumed for both.

- `Id`

Each node in the cluster has a unique identity, which is represented by an integer value in the range 1 to 63 inclusive. This ID is used by all internal cluster messages for addressing the node.

- `ExecuteOnComputer`

This refers to the `Id` set for one of the computers defined in a `[COMPUTER]` section of the `config.ini` file.

- `PortNumber`

This is the port number on which the management server listens for configuration requests and management commands.

- `HostName`

Specifying this parameter defines the hostname of the computer on which the management node is to reside. To specify a hostname other than `localhost`, either this parameter or `ExecuteOnComputer` is required.

- `LogDestination`

This parameter specifies where to send cluster logging information. There are three options in this regard: `CONSOLE`, `SYSLOG`, and `FILE`:

- `CONSOLE` outputs the log to `stdout`:

```
CONSOLE
```

- `SYSLOG` sends the log to a `syslog` facility, possible values being one of `auth`, `authpriv`, `cron`, `daemon`, `ftp`, `kern`, `lpr`, `mail`, `news`, `syslog`, `user`, `uucp`, `local0`, `local1`, `local2`, `local3`, `local4`, `local5`, `local6`, or `local7`.

Note: Not every facility is necessarily supported by every operating system.

```
SYSLOG:facility=syslog
```

- `FILE` pipes the cluster log output to a regular file on the same machine. The following values can be specified:

- `filename`: The name of the logfile.
- `maxsize`: The maximum size (in bytes) to which the file can grow before logging rolls over to a new file. When this occurs, the old logfile is renamed by appending `.N` to the filename, where `N` is the next number not yet used with this name.
- `maxfiles`: The maximum number of logfiles.

```
FILE:filename=cluster.log,maxsize=1000000,maxfiles=6
```

It is possible to specify multiple log destinations separated by semicolons as shown here:

```
CONSOLE;SYSLOG:facility=local0;FILE:filename=/var/log/mgmd
```

The default value for the `FILE` parameter is

```
FILE:filename=ndb_node_id_cluster.log,maxsize=1000000,maxfiles=6,
```

where `node_id` is the ID of the node.

- `ArbitrationRank`

This parameter is used to define which nodes can act as arbitrators. Only MGM nodes and SQL nodes can be arbitrators. `ArbitrationRank` can take one of the following values:

- `0`: The node will never be used as an arbitrator.
- `1`: The node has high priority; that is, it will be preferred as an arbitrator over low-priority nodes.
- `2`: Indicates a low-priority node which be used as an arbitrator only if a node with a higher priority is not available for that purpose.

Normally, the management server should be configured as an arbitrator by setting its `ArbitrationRank` to 1 (the default value) and that of all SQL nodes to 0.

- `ArbitrationDelay`

An integer value which causes the management server's responses to arbitration requests to be delayed by that number of milliseconds. By default, this value is 0; it is normally not necessary to change it.

-

`DataDir`

This specifies the directory where output files from the management server will be placed. These files include cluster log files, process output files, and the daemon's process ID (PID) file. (For log files, this location can be overridden by setting the `FILE` parameter for `LogDestination` as discussed previously in this section.)

15.4.4.5. Defining Data Nodes

The `[NDBD]` and `[NDBD DEFAULT]` sections are used to configure the behavior of the cluster's data nodes. There are many parameters which control buffer sizes, pool sizes, timeouts, and so forth. The only mandatory parameters are:

- Either `ExecuteOnComputer` or `HostName`, which must be defined in the local `[NDBD]` section.
- The parameter `NoOfReplicas`, which must be defined in the `[NDBD DEFAULT]` section, as it is common to all Cluster data nodes.

Most data node parameters are set in the `[NDBD DEFAULT]` section. Only those parameters explicitly stated as being able to set local values are allowed to be changed in the `[NDBD]` section. Where present, `HostName`, `Id` and `ExecuteOnComputer` *must* be defined in the local `[NDBD]` section, and not in any other section of `config.ini`. In other words, settings for these parameters are specific to one data node.

For those parameters affecting memory usage or buffer sizes, it is possible to use `K`, `M`, or `G` as a suffix to indicate units of 1024, 1024×1024, or 1024×1024×1024. (For example, `100K` means $100 \times 1024 = 102400$.) Parameter names and values are currently case-sensitive.

Identifying Data Nodes

The `Id` value (that is, the data node identifier) can be allocated on the command line when the node is started or in the configuration file.

-

`Id`

This is the node ID used as the address of the node for all cluster internal messages. This is an integer in the range 1 to 63 inclusive. Each node in the cluster must have a unique identity.

-

`ExecuteOnComputer`

This refers to the `Id` set for one of the computers defined in a `[COMPUTER]` section.

-

`HostName`

Specifying this parameter defines the hostname of the computer on which the data node is to reside. To specify a hostname other than `localhost`, either this parameter or `ExecuteOnComputer` is

required.

- `ServerPort` (*OBSOLETE*)

Each node in the cluster uses a port to connect to other nodes. This port is used also for non-TCP transporters in the connection setup phase. The default port is allocated dynamically in such a way as to ensure that no two nodes on the same computer receive the same port number, so it should not normally be necessary to specify a value for this parameter.

- `NoOfReplicas`

This global parameter can be set only in the `[NDBD DEFAULT]` section, and defines the number of replicas for each table stored in the cluster. This parameter also specifies the size of node groups. A node group is a set of nodes all storing the same information.

Node groups are formed implicitly. The first node group is formed by the set of data nodes with the lowest node IDs, the next node group by the set of the next lowest node identities, and so on. By way of example, assume that we have 4 data nodes and that `NoOfReplicas` is set to 2. The four data nodes have node IDs 2, 3, 4 and 5. Then the first node group is formed from nodes 2 and 3, and the second node group by nodes 4 and 5. It is important to configure the cluster in such a manner that nodes in the same node groups are not placed on the same computer because a single hardware failure would cause the entire cluster to crash.

If no node IDs are provided, the order of the data nodes will be the determining factor for the node group. Whether or not explicit assignments are made, they can be viewed in the output of the management client's `SHOW` statement.

There is no default value for `NoOfReplicas`; the maximum possible value is 4.

- `DataDir`

This parameter specifies the directory where trace files, log files, pid files and error logs are placed.

- `FileSystemPath`

This parameter specifies the directory where all files created for metadata, REDO logs, UNDO logs and data files are placed. The default is the directory specified by `DataDir`. **Note:** This directory must exist before the `ndbd` process is initiated.

The recommended directory hierarchy for MySQL Cluster includes `/var/lib/mysql-cluster`, under which a directory for the node's filesystem is created. The name of this subdirectory contains the node ID. For example, if the node ID is 2, this subdirectory is named `ndb_2_fs`.

- `BackupDataDir`

This parameter specifies the directory in which backups are placed. If omitted, the default backup location is the directory named `BACKUP` under the location specified by the `FileSystemPath` parameter. (See above.)

Data Memory, Index Memory, and String Memory

`DataMemory` and `IndexMemory` are `[NDBD]` parameters specifying the size of memory segments

used to store the actual records and their indexes. In setting values for these, it is important to understand how `DataMemory` and `IndexMemory` are used, as they usually need to be updated to reflect actual usage by the cluster:

- `DataMemory`

This parameter defines the amount of space (in bytes) available for storing database records. The entire amount specified by this value is allocated in memory, so it is extremely important that the machine has sufficient physical memory to accommodate it.

The memory allocated by `DataMemory` is used to store both the actual records and indexes. There is a 16-byte overhead on each record; an additional amount for each record is incurred because it is stored in a 32KB page with 128 byte page overhead (see below). There is also a small amount wasted per page due to the fact that each record is stored in only one page.

For variable-size table attributes in MySQL 5.1, the data is stored on separate datapages, allocated from `DataMemory`. Variable-length records use a fixed-size part with an extra overhead of 4 bytes to reference the variable-size part. The variable-size part has 2 bytes overhead plus 2 bytes per attribute.

The maximum record size is currently 8052 bytes.

The memory space defined by `DataMemory` is also used to store ordered indexes, which use about 10 bytes per record. Each table row is represented in the ordered index. A common error among users is to assume that all indexes are stored in the memory allocated by `IndexMemory`, but this is not the case: Only primary key and unique hash indexes use this memory; ordered indexes use the memory allocated by `DataMemory`. However, creating a primary key or unique hash index also creates an ordered index on the same keys, unless you specify `USING HASH` in the index creation statement. This can be verified by running `ndb_desc -d db_name table_name` in the management client.

The memory space allocated by `DataMemory` consists of 32KB pages, which are allocated to table fragments. Each table is normally partitioned into the same number of fragments as there are data nodes in the cluster. Thus, for each node, there are the same number of fragments as are set in `NoOfReplicas`.

Once a page has been allocated, it is currently not possible to return it to the pool of free pages, except by deleting the table. (This also means that `DataMemory` pages, once allocated to a given table, cannot be used by other tables.) Performing a node recovery also compresses the partition because all records are inserted into empty partitions from other live nodes.

The `DataMemory` memory space also contains UNDO information: For each update, a copy of the unaltered record is allocated in the `DataMemory`. There is also a reference to each copy in the ordered table indexes. Unique hash indexes are updated only when the unique index columns are updated, in which case a new entry in the index table is inserted and the old entry is deleted upon commit. For this reason, it is also necessary to allocate enough memory to handle the largest transactions performed by applications using the cluster. In any case, performing a few large transactions holds no advantage over using many smaller ones, for the following reasons:

- Large transactions are not any faster than smaller ones
- Large transactions increase the number of operations that are lost and must be repeated in event of transaction failure
- Large transactions use more memory

The default value for `DataMemory` is 80MB; the minimum is 1MB. There is no maximum size, but in reality the maximum size has to be adapted so that the process does not start swapping when the

limit is reached. This limit is determined by the amount of physical RAM available on the machine and by the amount of memory that the operating system may commit to any one process. 32-bit operating systems are generally limited to 2–4GB per process; 64-bit operating systems can use more. For large databases, it may be preferable to use a 64-bit operating system for this reason.

- [IndexMemory](#)

This parameter controls the amount of storage used for hash indexes in MySQL Cluster. Hash indexes are always used for primary key indexes, unique indexes, and unique constraints. Note that when defining a primary key and a unique index, two indexes will be created, one of which is a hash index used for all tuple accesses as well as lock handling. It is also used to enforce unique constraints.

The size of the hash index is 25 bytes per record, plus the size of the primary key. For primary keys larger than 32 bytes another 8 bytes is added.

The default value for [IndexMemory](#) is 18MB. The minimum is 1MB.

- [StringMemory](#)

This parameter determines how much memory is allocated for strings such as table names, and is specified in an [\[NDBD\]](#) or [\[NDBD DEFAULT\]](#) section of the `config.ini` file. A value between 0 and 100 inclusive is interpreted as a percent of the maximum default value, which is calculated based on a number of factors including the number of tables, maximum table name size, maximum size of `.FRM` files, [MaxNoOfTriggers](#), maximum column name size, and maximum default column value. In general it is safe to assume that the maximum default value is approximately 5 MB for a MySQL Cluster having 1000 tables.

A value greater than 100 is interpreted as a number of bytes.

The default value is 5 — that is, 5 percent of the default maximum, or roughly 5 KB. (Note that this is a change from previous versions of MySQL Cluster.)

Under most circumstances, the default value should be sufficient, but when you have a great many Cluster tables (1000 or more), it is possible to get Error 773 Out of string memory, please modify `StringMemory` config parameter: Permanent error: Schema error, in which case you should increase this value. 25 (25 percent) is not excessive, and should prevent this error from recurring in all but the most extreme conditions.

The following example illustrates how memory is used for a table. Consider this table definition:

```
CREATE TABLE example (
  a INT NOT NULL,
  b INT NOT NULL,
  c INT NOT NULL,
  PRIMARY KEY(a),
  UNIQUE(b)
) ENGINE=NDBCLUSTER;
```

For each record, there are 12 bytes of data plus 12 bytes overhead. Having no nullable columns saves 4 bytes of overhead. In addition, we have two ordered indexes on columns `a` and `b` consuming roughly 10 bytes each per record. There is a primary key hash index on the base table using roughly 29 bytes per record. The unique constraint is implemented by a separate table with `b` as primary key and `a` as a column. This other table consumes an additional 29 bytes of index memory per record in the `example` table as well 8 bytes of record data plus 12 bytes of overhead.

Thus, for one million records, we need 58MB for index memory to handle the hash indexes for the

primary key and the unique constraint. We also need 64MB for the records of the base table and the unique index table, plus the two ordered index tables.

You can see that hash indexes takes up a fair amount of memory space; however, they provide very fast access to the data in return. They are also used in MySQL Cluster to handle uniqueness constraints.

Currently, the only partitioning algorithm is hashing and ordered indexes are local to each node. Thus, ordered indexes cannot be used to handle uniqueness constraints in the general case.

An important point for both `IndexMemory` and `DataMemory` is that the total database size is the sum of all data memory and all index memory for each node group. Each node group is used to store replicated information, so if there are four nodes with two replicas, there will be two node groups. Thus, the total data memory available is $2 \times \text{DataMemory}$ for each data node.

It is highly recommended that `DataMemory` and `IndexMemory` be set to the same values for all nodes. Data distribution is even over all nodes in the cluster, so the maximum amount of space available for any node can be no greater than that of the smallest node in the cluster.

`DataMemory` and `IndexMemory` can be changed, but decreasing either of these can be risky; doing so can easily lead to a node or even an entire MySQL Cluster that is unable to restart due to there being insufficient memory space. Increasing these values should be acceptable, but it is recommended that such upgrades are performed in the same manner as a software upgrade, beginning with an update of the configuration file, and then restarting the management server followed by restarting each data node in turn.

Updates do not increase the amount of index memory used. Inserts take effect immediately; however, rows are not actually deleted until the transaction is committed.

Transaction Parameters

The next three `[NDBD]` parameters that we discuss are important because they affect the number of parallel transactions and the sizes of transactions that can be handled by the system. `MaxNoOfConcurrentTransactions` sets the number of parallel transactions possible in a node. `MaxNoOfConcurrentOperations` sets the number of records that can be in update phase or locked simultaneously.

Both of these parameters (especially `MaxNoOfConcurrentOperations`) are likely targets for users setting specific values and not using the default value. The default value is set for systems using small transactions, to ensure that these do not use excessive memory.

- `MaxNoOfConcurrentTransactions`

For each active transaction in the cluster there must be a record in one of the cluster nodes. The task of coordinating transactions is spread among the nodes. The total number of transaction records in the cluster is the number of transactions in any given node times the number of nodes in the cluster.

Transaction records are allocated to individual MySQL servers. Normally, there is at least one transaction record allocated per connection that using any table in the cluster. For this reason, one should ensure that there are more transaction records in the cluster than there are concurrent connections to all MySQL servers in the cluster.

This parameter must be set to the same value for all cluster nodes.

Changing this parameter is never safe and doing so can cause a cluster to crash. When a node crashes, one of the nodes (actually the oldest surviving node) will build up the transaction state of all transactions ongoing in the crashed node at the time of the crash. It is thus important that this node has as many transaction records as the failed node.

The default value is 4096.

- [MaxNoOfConcurrentOperations](#)

It is a good idea to adjust the value of this parameter according to the size and number of transactions. When performing transactions of only a few operations each and not involving a great many records, there is no need to set this parameter very high. When performing large transactions involving many records need to set this parameter higher.

Records are kept for each transaction updating cluster data, both in the transaction coordinator and in the nodes where the actual updates are performed. These records contain state information needed to find UNDO records for rollback, lock queues, and other purposes.

This parameter should be set to the number of records to be updated simultaneously in transactions, divided by the number of cluster data nodes. For example, in a cluster which has four data nodes and which is expected to handle 1,000,000 concurrent updates using transactions, you should set this value to $1000000 / 4 = 250000$.

Read queries which set locks also cause operation records to be created. Some extra space is allocated within individual nodes to accommodate cases where the distribution is not perfect over the nodes.

When queries make use of the unique hash index, there are actually two operation records used per record in the transaction. The first record represents the read in the index table and the second handles the operation on the base table.

The default value is 32768.

This parameter actually handles two values that can be configured separately. The first of these specifies how many operation records are to be placed with the transaction coordinator. The second part specifies how many operation records are to be local to the database.

A very large transaction performed on an eight-node cluster requires as many operation records in the transaction coordinator as there are reads, updates, and deletes involved in the transaction. However, the operation records of the are spread over all eight nodes. Thus, if it is necessary to configure the system for one very large transaction, it is a good idea to configure the two parts separately. [MaxNoOfConcurrentOperations](#) will always be used to calculate the number of operation records in the transaction coordinator portion of the node.

It is also important to have an idea of the memory requirements for operation records. These consume about 1KB per record.

- [MaxNoOfLocalOperations](#)

By default, this parameter is calculated as $1.1 \times \text{MaxNoOfConcurrentOperations}$. This fits systems with many simultaneous transactions, none of them being very large. If there is a need to handle one very large transaction at a time and there are many nodes, it is a good idea to override the default value by explicitly specifying this parameter.

Transaction Temporary Storage

The next set of [\[NDBD\]](#) parameters is used to determine temporary storage when executing a statement that is part of a Cluster transaction. All records are released when the statement is completed and the cluster is waiting for the commit or rollback.

The default values for these parameters are adequate for most situations. However, users with a need to support transactions involving large numbers of rows or operations may need to increase these values to enable better parallelism in the system, whereas users whose applications require relatively small transactions can decrease the values to save memory.

-

`MaxNoOfConcurrentIndexOperations`

For queries using a unique hash index, another temporary set of operation records is used during a query's execution phase. This parameter sets the size of that pool of records. Thus, this record is allocated only while executing a part of a query. As soon as this part has been executed, the record is released. The state needed to handle aborts and commits is handled by the normal operation records, where the pool size is set by the parameter `MaxNoOfConcurrentOperations`.

The default value of this parameter is 8192. Only in rare cases of extremely high parallelism using unique hash indexes should it be necessary to increase this value. Using a smaller value is possible and can save memory if the DBA is certain that a high degree of parallelism is not required for the cluster.

-

`MaxNoOfFiredTriggers`

The default value of `MaxNoOfFiredTriggers` is 4000, which is sufficient for most situations. In some cases it can even be decreased if the DBA feels certain the need for parallelism in the cluster is not high.

A record is created when an operation is performed that affects a unique hash index. Inserting or deleting a record in a table with unique hash indexes or updating a column that is part of a unique hash index fires an insert or a delete in the index table. The resulting record is used to represent this index table operation while waiting for the original operation that fired it to complete. This operation is short-lived but can still require a large number of records in its pool for situations with many parallel write operations on a base table containing a set of unique hash indexes.

-

`TransactionBufferMemory`

The memory affected by this parameter is used for tracking operations fired when updating index tables and reading unique indexes. This memory is used to store the key and column information for these operations. It is only very rarely that the value for this parameter needs to be altered from the default.

The default value for `TransactionBufferMemory` is 1MB.

Normal read and write operations use a similar buffer, whose usage is even more short-lived. The compile-time parameter `ZATTRBUF_FILESIZE` (found in `ndb/src/kernel/blocks/Dbtc/Dbtc.hpp`) set to 4000×128 bytes (500KB). A similar buffer for key information, `ZDATABUF_FILESIZE` (also in `Dbtc.hpp`) contains $4000 \times 16 = 62.5$ KB of buffer space. `Dbtc` is the module that handles transaction coordination.

Scans and Buffering

There are additional [NDBD] parameters in the `Dbtqh` module (in `ndb/src/kernel/blocks/Dbtqh/Dbtqh.hpp`) that affect reads and updates. These include `ZATTRINBUF_FILESIZE`, set by default to 10000×128 bytes (1250KB) and `ZDATABUF_FILE_SIZE`, set by default to 10000×16 bytes (roughly 156KB) of buffer space. To date, there have been neither any reports from users nor any results from our own extensive tests suggesting that either of these compile-time limits should be increased.

- [MaxNoOfConcurrentScans](#)

This parameter is used to control the number of parallel scans that can be performed in the cluster. Each transaction coordinator can handle the number of parallel scans defined for this parameter. Each scan query is performed by scanning all partitions in parallel. Each partition scan uses a scan record in the node where the partition is located, the number of records being the value of this parameter times the number of nodes. The cluster should be able to sustain [MaxNoOfConcurrentScans](#) scans concurrently from all nodes in the cluster.

Scans are actually performed in two cases. The first of these cases occurs when no hash or ordered indexes exists to handle the query, in which case the query is executed by performing a full table scan. The second case is encountered when there is no hash index to support the query but there is an ordered index. Using the ordered index means executing a parallel range scan. The order is kept on the local partitions only, so it is necessary to perform the index scan on all partitions.

The default value of [MaxNoOfConcurrentScans](#) is 256. The maximum value is 500.

This parameter specifies the number of scans possible in the transaction coordinator. If the number of local scan records is not provided, it is calculated as the product of [MaxNoOfConcurrentScans](#) and the number of data nodes in the system.

- [MaxNoOfLocalScans](#)

Specifies the number of local scan records if many scans are not fully parallelized.

- [BatchSizePerLocalScan](#)

This parameter is used to calculate the number of lock records which must be there to handle many concurrent scan operations.

The default value is 64; this value has a strong connection to the [ScanBatchSize](#) defined in the SQL nodes.

- [LongMessageBuffer](#)

This is an internal buffer used for passing messages within individual nodes and between nodes. Although it is highly unlikely that this would need to be changed, it is configurable. By default, it is set to 1MB.

Logging and Checkpointing

These [\[NDBD\]](#) parameters control log and checkpoint behavior.

- [NoOfFragmentLogFiles](#)

This parameter sets the number of REDO log files for the node, and thus the amount of space allocated to REDO logging. Because the REDO log files are organized in a ring, it is extremely important that the first and last log files in the set (sometimes referred to as the “head” and “tail” log files, respectively) do not meet. When these approach one another too closely, the node begins aborting all transactions encompassing updates due to a lack of room for new log records.

A REDO log record is not removed until three local checkpoints have been completed since that log record was inserted. Checkpointing frequency is determined by its own set of configuration paramet-

ers discussed elsewhere in this chapter.

How these parameters interact and proposals for how to configure them are discussed in [Section 15.4.6, “Configuring Parameters for Local Checkpoints”](#).

The default parameter value is 8, which means 8 sets of 4 16MB files for a total of 512MB. In other words, REDO log space must be allocated in blocks of 64MB. In scenarios requiring a great many updates, the value for `NoOfFragmentLogFiles` may need to be set as high as 300 or even higher to provide sufficient space for REDO logs.

If the checkpointing is slow and there are so many writes to the database that the log files are full and the log tail cannot be cut without jeopardizing recovery, all updating transactions are aborted with internal error code 410 (`Out of log file space temporarily`). This condition prevails until a checkpoint has completed and the log tail can be moved forward.

Important: This parameter cannot be changed “on the fly”; you must restart the node using `-initial`. If you wish to change this value for a running cluster, you can do so via a rolling node restart.

- `MaxNoOfOpenFiles`

This parameter sets a ceiling on how many internal threads to allocate for open files. *Any situation requiring a change in this parameter should be reported as a bug.*

The default value is 40.

- `MaxNoOfSavedMessages`

This parameter sets the maximum number of trace files that are kept before overwriting old ones. Trace files are generated when, for whatever reason, the node crashes.

The default is 25 trace files.

Metadata Objects

The next set of `[NDBD]` parameters defines pool sizes for metadata objects, used to define the maximum number of attributes, tables, indexes, and trigger objects used by indexes, events, and replication between clusters. Note that these act merely as “suggestions” to the cluster, and any that are not specified revert to the default values shown.

- `MaxNoOfAttributes`

Defines the number of attributes that can be defined in the cluster.

The default value is 1000, with the minimum possible value being 32. The maximum is 4294967039. Each attribute consumes around 200 bytes of storage per node due to the fact that all metadata is fully replicated on the servers.

When setting `MaxNoOfAttributes`, it is important to prepare in advance for any `ALTER TABLE` statements that you might want to perform in the future. This is due to the fact, during the execution of `ALTER TABLE` on a Cluster table, 3 times the number of attributes as in the original table are used. For example, if a table requires 100 attributes, and you want to be able to alter it later, you need to set the value of `MaxNoOfAttributes` to 300. Assuming that you can create all desired tables without any problems, a good rule of thumb is to add two times the number of attributes in the

largest table to `MaxNoOfAttributes` to be sure. You should also verify that this number is sufficient by trying an actual `ALTER TABLE` after configuring the parameter. If this is not successful, increase `MaxNoOfAttributes` by another multiple of the original value and test it again.

- `MaxNoOfTables`

A table object is allocated for each table, unique hash index, and ordered index. This parameter sets the maximum number of table objects for the cluster as a whole.

For each attribute that has a `BLOB` data type an extra table is used to store most of the `BLOB` data. These tables also must be taken into account when defining the total number of tables.

The default value of this parameter is 128. The minimum is 8 and the maximum is 1600. Each table object consumes approximately 20KB per node.

- `MaxNoOfOrderedIndexes`

For each ordered index in the cluster, an object is allocated describing what is being indexed and its storage segments. By default, each index so defined also defines an ordered index. Each unique index and primary key has both an ordered index and a hash index.

The default value of this parameter is 128. Each object consumes approximately 10KB of data per node.

- `MaxNoOfUniqueHashIndexes`

For each unique index that is not a primary key, a special table is allocated that maps the unique key to the primary key of the indexed table. By default, an ordered index is also defined for each unique index. To prevent this, you must specify the `USING HASH` option when defining the unique index.

The default value is 64. Each index consumes approximately 15KB per node.

- `MaxNoOfTriggers`

Internal update, insert, and delete triggers are allocated for each unique hash index. (This means that three triggers are created for each unique hash index.) However, an *ordered* index requires only a single trigger object. Backups also use three trigger objects for each normal table in the cluster.

Replication between clusters also makes use of internal triggers.

This parameter sets the maximum number of trigger objects in the cluster.

The default value is 768.

- `MaxNoOfIndexes`

This parameter is deprecated in MySQL 5.1; you should use `MaxNoOfOrderedIndexes` and `MaxNoOfUniqueHashIndexes` instead.

This parameter is used only by unique hash indexes. There needs to be one record in this pool for each unique hash index defined in the cluster.

The default value of this parameter is 128.

Boolean Parameters

The behavior of data nodes is also affected by a set of [NDBD] parameters taking on boolean values. These parameters can each be specified as `TRUE` by setting them equal to `1` or `Y`, and as `FALSE` by setting them equal to `0` or `N`.

- `LockPagesInMainMemory`

For a number of operating systems, including Solaris and Linux, it is possible to lock a process into memory and so avoid any swapping to disk. This can be used to help guarantee the cluster's real-time characteristics.

This feature is disabled by default.

- `StopOnError`

This parameter specifies whether an `ndbd` process should exit or perform an automatic restart when an error condition is encountered.

This feature is enabled by default.

- `Diskless`

It is possible to specify MySQL Cluster tables as *diskless*, meaning that tables are not checkpointed to disk and that no logging occurs. Such tables exist only in main memory. A consequence of using diskless tables is that neither the tables nor the records in those tables survive a crash. However, when operating in diskless mode, it is possible to run `ndbd` on a diskless computer.

Important: This feature causes the *entire* cluster to operate in diskless mode.

When this feature is enabled, Cluster online backup is disabled. In addition, a partial start of the cluster is not possible.

`Diskless` is disabled by default.

- `RestartOnErrorInsert`

This feature is accessible only when building the debug version where it is possible to insert errors in the execution of individual blocks of code as part of testing.

This feature is disabled by default.

Controlling Timeouts, Intervals, and Disk Paging

There are a number of [NDBD] parameters specifying timeouts and intervals between various actions in Cluster data nodes. Most of the timeout values are specified in milliseconds. Any exceptions to this are mentioned where applicable.

- `TimeBetweenWatchDogCheck`

To prevent the main thread from getting stuck in an endless loop at some point, a “watchdog” thread checks the main thread. This parameter specifies the number of milliseconds between checks. If the

process remains in the same state after three checks, the watchdog thread terminates it.

This parameter can easily be changed for purposes of experimentation or to adapt to local conditions. It can be specified on a per-node basis although there seems to be little reason for doing so.

The default timeout is 4000 milliseconds (4 seconds).

- `StartPartialTimeout`

This parameter specifies how long the Cluster waits for all data nodes to come up before the cluster initialization routine is invoked. This timeout is used to avoid a partial Cluster startup whenever possible.

The default value is 30000 milliseconds (30 seconds). 0 disables the timeout. In other words, the cluster may start only if all nodes are available.

- `StartPartitionedTimeout`

If the cluster is ready to start after waiting for `StartPartialTimeout` milliseconds but is still possibly in a partitioned state, the cluster waits until this timeout has also passed.

The default timeout is 60000 milliseconds (60 seconds).

- `StartFailureTimeout`

If a data node has not completed its startup sequence within the time specified by this parameter, the node startup fails. Setting this parameter to 0 (the default value) means that no data node timeout is applied.

For nonzero values, this parameter is measured in milliseconds. For data nodes containing extremely large amounts of data, this parameter should be increased. For example, in the case of a data node containing several gigabytes of data, a period as long as 10–15 minutes (that is, 600000 to 1000000 milliseconds) might be required to perform a node restart.

- `HeartbeatIntervalDbDb`

One of the primary methods of discovering failed nodes is by the use of heartbeats. This parameter states how often heartbeat signals are sent and how often to expect to receive them. After missing three heartbeat intervals in a row, the node is declared dead. Thus, the maximum time for discovering a failure through the heartbeat mechanism is four times the heartbeat interval.

The default heartbeat interval is 1500 milliseconds (1.5 seconds). This parameter must not be changed drastically and should not vary widely between nodes. If one node uses 5000 milliseconds and the node watching it uses 1000 milliseconds, obviously the node will be declared dead very quickly. This parameter can be changed during an online software upgrade, but only in small increments.

- `HeartbeatIntervalDbApi`

Each data node sends heartbeat signals to each MySQL server (SQL node) to ensure that it remains in contact. If a MySQL server fails to send a heartbeat in time it is declared “dead,” in which case all ongoing transactions are completed and all resources released. The SQL node cannot reconnect until all activities initiated by the previous MySQL instance have been completed. The three-heartbeat cri-

teria for this determination are the same as described for [HeartbeatIntervalDbDb](#).

The default interval is 1500 milliseconds (1.5 seconds). This interval can vary between individual data nodes because each data node watches the MySQL servers connected to it, independently of all other data nodes.

- [TimeBetweenLocalCheckpoints](#)

This parameter is an exception in that it does not specify a time to wait before starting a new local checkpoint; rather, it is used to ensure that local checkpoints are not performed in a cluster where relatively few updates are taking place. In most clusters with high update rates, it is likely that a new local checkpoint is started immediately after the previous one has been completed.

The size of all write operations executed since the start of the previous local checkpoints is added. This parameter is also exceptional in that it is specified as the base-2 logarithm of the number of 4-byte words, so that the default value 20 means 4MB (4×2^{20}) of write operations, 21 would mean 8MB, and so on up to a maximum value of 31, which equates to 8GB of write operations.

All the write operations in the cluster are added together. Setting [TimeBetweenLocalCheckpoints](#) to 6 or less means that local checkpoints will be executed continuously without pause, independent of the cluster's workload.

- [TimeBetweenGlobalCheckpoints](#)

When a transaction is committed, it is committed in main memory in all nodes on which the data is mirrored. However, transaction log records are not flushed to disk as part of the commit. The reasoning behind this behavior is that having the transaction safely committed on at least two autonomous host machines should meet reasonable standards for durability.

It is also important to ensure that even the worst of cases — a complete crash of the cluster — is handled properly. To guarantee that this happens, all transactions taking place within a given interval are put into a global checkpoint, which can be thought of as a set of committed transactions that has been flushed to disk. In other words, as part of the commit process, a transaction is placed in a global checkpoint group. Later, this group's log records are flushed to disk, and then the entire group of transactions is safely committed to disk on all computers in the cluster.

This parameter defines the interval between global checkpoints. The default is 2000 milliseconds.

- [TimeBetweenInactiveTransactionAbortCheck](#)

Timeout handling is performed by checking a timer on each transaction once for every interval specified by this parameter. Thus, if this parameter is set to 1000 milliseconds, every transaction will be checked for timing out once per second.

The default value is 1000 milliseconds (1 second).

- [TransactionInactiveTimeout](#)

This parameter states the maximum time that is permitted to lapse between operations in the same transaction before the transaction is aborted.

The default for this parameter is zero (no timeout). For a real-time database that needs to ensure that no transaction keeps locks for too long, this parameter should be set to a much smaller value. The unit is milliseconds.

- [TransactionDeadlockDetectionTimeout](#)

When a node executes a query involving a transaction, the node waits for the other nodes in the cluster to respond before continuing. A failure to respond can occur for any of the following reasons:

- The node is “dead”
- The operation has entered a lock queue
- The node requested to perform the action could be heavily overloaded.

This timeout parameter states how long the transaction coordinator waits for query execution by another node before aborting the transaction, and is important for both node failure handling and deadlock detection. Setting it too high can cause a undesirable behavior in situations involving deadlocks and node failure.

The default timeout value is 1200 milliseconds (1.2 seconds).

- [NoOfDiskPagesToDiskAfterRestartTUP](#)

When executing a local checkpoint, the algorithm flushes all data pages to disk. Merely doing so as quickly as possible without any moderation is likely to impose excessive loads on processors, networks, and disks. To control the write speed, this parameter specifies how many pages per 100 milliseconds are to be written. In this context, a “page” is defined as 8KB. This parameter is specified in units of 80KB per second, so , setting [NoOfDiskPagesToDiskAfterRestartTUP](#) to a value of 20 entails writing 1.6MB in data pages to disk each second during a local checkpoint. This value includes the writing of UNDO log records for data pages. That is, this parameter handles the limitation of writes from data memory. UNDO log records for index pages are handled by the parameter [NoOfDiskPagesToDiskAfterRestartACC](#). (See the entry for [IndexMemory](#) for information about index pages.)

In short, this parameter specifies how quickly to execute local checkpoints. It operates in conjunction with [NoOfFragmentLogFiles](#), [DataMemory](#), and [IndexMemory](#).

For more information about the interaction between these parameters and possible strategies for choosing appropriate values for them, see [Section 15.4.6, “Configuring Parameters for Local Checkpoints”](#).

The default value is 40 (3.2MB of data pages per second).

- [NoOfDiskPagesToDiskAfterRestartACC](#)

This parameter uses the same units as [NoOfDiskPagesToDiskAfterRestartTUP](#) and acts in a similar fashion, but limits the speed of writing index pages from index memory.

The default value of this parameter is 20 (1.6MB of index memory pages per second).

- [NoOfDiskPagesToDiskDuringRestartTUP](#)

This parameter is used in a fashion similar to [NoOfDiskPagesToDiskAfterRestartTUP](#) and [NoOfDiskPagesToDiskAfterRestartACC](#), only it does so with regard to local checkpoints executed in the node when a node is restarting. A local checkpoint is always performed as part of all node restarts. During a node restart it is possible to write to disk at a higher speed than at other times, because fewer activities are being performed in the node.

This parameter covers pages written from data memory.

The default value is 40 (3.2MB per second).

- [NoOfDiskPagesToDiskDuringRestartACC](#)

Controls the number of index memory pages that can be written to disk during the local checkpoint phase of a node restart.

As with [NoOfDiskPagesToDiskAfterRestartTUP](#) and [NoOfDiskPagesToDiskAfterRestartACC](#), values for this parameter are expressed in terms of 8KB pages written per 100 milliseconds (80KB/second).

The default value is 20 (1.6MB per second).

- [ArbitrationTimeout](#)

This parameter specifies how long data nodes wait for a response from the arbitrator to an arbitration message. If this is exceeded, the network is assumed to have split.

The default value is 1000 milliseconds (1 second).

Buffering and Logging

[RedoBuffer](#)

All update activities need to be logged. The REDO log makes it possible to replay these updates whenever the system is restarted. The NDB recovery algorithm uses a “fuzzy” checkpoint of the data together with the UNDO log, and then applies the REDO log to play back all changes up to the restoration point.

[RedoBuffer](#) sets the size of the buffer in which the REDO log is written, and is 8MB by default. This buffer is used as a front end to the file system when writing REDO log records to disk. If this buffer is too small, the NDB storage engine issues error code 1221 ([REDO log buffers overloaded](#)).

The minimum value is 1MB. If the node is running in diskless mode, these parameters can be set to their minimum values without penalty due to the fact that disk writes are “faked” by the NDB storage engine's filesystem abstraction layer.

Important: It is not safe to decrease the value of this parameter during a rolling restart.

Note: The [UndoIndexBuffer](#) and [UndoDataBuffer](#) parameters which appeared in earlier versions of MySQL Cluster are no longer necessary (or even present) in MySQL 5.1.

Controlling Log Messages

In managing the cluster, it is very important to be able to control the number of log messages sent for various event types to [stdout](#). For each event category, there are 16 possible event levels (numbered 0 through 15). Setting event reporting for a given event category to level 15 means all event reports in that category are sent to [stdout](#); setting it to 0 means that there will be no event reports made in that category.

By default, only the startup message is sent to [stdout](#), with the remaining event reporting level defaults being set to 0. The reason for this is that these messages are also sent to the management server's cluster log.

An analogous set of levels can be set for the management client to determine which event levels to record in the cluster log.

- `LogLevelStartup`
The reporting level for events generated during startup of the process.
The default level is 1.
- `LogLevelShutdown`
The reporting level for events generated as part of graceful shutdown of a node.
The default level is 0.
- `LogLevelStatistic`
The reporting level for statistical events such as number of primary key reads, number of updates, number of inserts, information relating to buffer usage, and so on.
The default level is 0.
- `LogLevelCheckpoint`
The reporting level for events generated by local and global checkpoints.
The default level is 0.
- `LogLevelNodeRestart`
The reporting level for events generated during node restart.
The default level is 0.
- `LogLevelConnection`
The reporting level for events generated by connections between cluster nodes.
The default level is 0.
- `LogLevelError`
The reporting level for events generated by errors and warnings by the cluster as a whole. These errors do not cause any node failure but are still considered worth reporting.
The default level is 0.
- `LogLevelInfo`
The reporting level for events generated for information about the general state of the cluster.

The default level is 0.

Backup Parameters

The [NDBD] parameters discussed in this section define memory buffers set aside for execution of on-line backups.

- [BackupDataBufferSize](#)

In creating a backup, there are two buffers used for sending data to the disk. The backup data buffer is used to fill in data recorded by scanning a node's tables. Once this buffer has been filled to the level specified as [BackupWriteSize](#) (see below), the pages are sent to disk. While flushing data to disk, the backup process can continue filling this buffer until it runs out of space. When this happens, the backup process pauses the scan and waits until some disk writes have completed freed up memory so that scanning may continue.

The default value is 2MB.

- [BackupLogBufferSize](#)

The backup log buffer fulfills a role similar to that played by the backup data buffer, except that it is used for generating a log of all table writes made during execution of the backup. The same principles apply for writing these pages as with the backup data buffer, except that when there is no more space in the backup log buffer, the backup fails. For that reason, the size of the backup log buffer must be large enough to handle the load caused by write activities while the backup is being made. See [Section 15.8.4, “Configuration for Cluster Backup”](#).

The default value for this parameter should be sufficient for most applications. In fact, it is more likely for a backup failure to be caused by insufficient disk write speed than it is for the backup log buffer to become full. If the disk subsystem is not configured for the write load caused by applications, the cluster is unlikely to be able to perform the desired operations.

It is preferable to configure cluster nodes in such a manner that the processor becomes the bottleneck rather than the disks or the network connections.

The default value is 2MB.

- [BackupMemory](#)

This parameter is simply the sum of [BackupDataBufferSize](#) and [BackupLogBufferSize](#).

The default value is $2\text{MB} + 2\text{MB} = 4\text{MB}$.

Important: If [BackupDataBufferSize](#) and [BackupLogBufferSize](#) taken together exceed 4MB, then this parameter must be set explicitly in the `config.ini` file to their sum.

- [BackupWriteSize](#)

This parameter specifies the default size of messages written to disk by the backup log and backup data buffers.

The default value is 32KB.

- `BackupMaxWriteSize`

This parameter specifies the maximum size of messages written to disk by the backup log and backup data buffers.

The default value is 256KB.

Important: When specifying these parameters, the following relationships must hold true. Otherwise, the data node will be unable to start.

- `BackupDataBufferSize >= BackupWriteSize + 188KB`
- `BackupLogBufferSize >= BackupWriteSize + 16KB`
- `BackupMaxWriteSize >= BackupWriteSize`

15.4.4.6. Defining SQL and Other API Nodes

The `[MYSQLD]` and `[API]` sections in the `config.ini` file define the behavior of the MySQL servers (SQL nodes) and other applications (API nodes) used to access cluster data. None of the parameters shown is required. If no computer or host name is provided, any host can use this SQL or API node.

Generally speaking, a `[MYSQLD]` section is used to indicate a MySQL server providing an SQL interface to the cluster, and an `[API]` section is used for applications other than `mysqld` processes accessing cluster data, but the two designations are actually synonymous; you can, for instance, list parameters for a MySQL server acting as an SQL node in an `[API]` section.

- `Id`

The `Id` value is used to identify the node in all cluster internal messages. It must be an integer in the range 1 to 63 inclusive, and must be unique among all node IDs within the cluster.
- `ExecuteOnComputer`

This refers to the `Id` set for one of the computers (hosts) defined in a `[COMPUTER]` section of the configuration file.
- `HostName`

Specifying this parameter defines the hostname of the computer on which the SQL node (API node) is to reside. To specify a hostname other than `localhost`, either this parameter or `ExecuteOnComputer` is required.
- `ArbitrationRank`

This parameter defines which nodes can act as arbitrators. Both MGM nodes and SQL nodes can be arbitrators. A value of 0 means that the given node is never used as an arbitrator, a value of 1 gives the node high priority as an arbitrator, and a value of 2 gives it low priority. A normal configuration uses the management server as arbitrator, setting its `ArbitrationRank` to 1 (the default) and those for all SQL nodes to 0.

- [ArbitrationDelay](#)
Setting this parameter to any other value than 0 (the default) means that responses by the arbitrator to arbitration requests will be delayed by the stated number of milliseconds. It is usually not necessary to change this value.
- [BatchByteSize](#)
For queries that are translated into full table scans or range scans on indexes, it is important for best performance to fetch records in properly sized batches. It is possible to set the proper size both in terms of number of records ([BatchSize](#)) and in terms of bytes ([BatchByteSize](#)). The actual batch size is limited by both parameters.

The speed at which queries are performed can vary by more than 40% depending upon how this parameter is set. In future releases, MySQL Server will make educated guesses on how to set parameters relating to batch size, based on the query type.

This parameter is measured in bytes and by default is equal to 32KB.
- [BatchSize](#)
This parameter is measured in number of records and is by default set to 64. The maximum size is 992.
- [MaxScanBatchSize](#)
The batch size is the size of each batch sent from each data node. Most scans are performed in parallel to protect the MySQL Server from receiving too much data from many nodes in parallel; this parameter sets a limit to the total batch size over all nodes.

The default value of this parameter is set to 256KB. Its maximum size is 16MB.

You can obtain some information from a MySQL server running as a Cluster SQL node using [SHOW STATUS](#) in the `mysql` client, as shown here:

```
mysql> SHOW STATUS LIKE 'ndb%';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| Ndb_cluster_node_id | 5 |
| Ndb_config_from_host | 192.168.0.112 |
| Ndb_config_from_port | 1186 |
| Ndb_number_of_storage_nodes | 4 |
+-----+-----+
4 rows in set (0.02 sec)
```

For information about these Cluster system status variables, see [Section 5.2.5, “Status Variables”](#).

15.4.4.7. Cluster TCP/IP Connections

TCP/IP is the default transport mechanism for establishing connections in MySQL Cluster. It is normally not necessary to define connections because Cluster automatically set ups a connection between each of the data nodes, between each data node and all MySQL server nodes, and between each data node and the management server. (For one exception to this rule, see [Section 15.4.4.8, “TCP/IP Connections Using Direct Connections”](#).) [TCP] sections in the `config.ini` file explicitly define TCP/IP connections between nodes in the cluster.

It is only necessary to define a connection to override the default connection parameters. In that case, it is necessary to define at least `NodeId1`, `NodeId2`, and the parameters to change.

It is also possible to change the default values for these parameters by setting them in the `[TCP DEFAULT]` section.

- `NodeId1`, `NodeId2`

To identify a connection between two nodes it is necessary to provide their node IDs in the `[TCP]` section of the configuration file. These are the same unique `Id` values for each of these nodes as described in [Section 15.4.4.6, “Defining SQL and Other API Nodes”](#).

- `SendBufferMemory`

TCP transporters use a buffer to store all messages before performing the send call to the operating system. When this buffer reaches 64KB its contents are sent; these are also sent when a round of messages have been executed. To handle temporary overload situations it is also possible to define a bigger send buffer. The default size of the send buffer is 256KB.

- `SendSignalId`

To be able to retrace a distributed message datagram, it is necessary to identify each message. When this parameter is set to `Y`, message IDs are transported over the network. This feature is disabled by default in production builds, and enabled in `-debug` builds.

- `Checksum`

This parameter is a boolean parameter (enabled by setting it to `Y` or `1`, disabled by setting it to `N` or `0`). It is disabled by default. When it is enabled, checksums for all messages are calculated before they placed in the send buffer. This feature ensures that messages are not corrupted while waiting in the send buffer, or by the transport mechanism.

- `PortNumber` (*OBSOLETE*)

This formerly specified the port number to be used for listening for connections from other nodes. This parameter should no longer be used.

- `ReceiveBufferMemory`

Specifies the size of the buffer used when receiving data from the TCP/IP socket. There is seldom any need to change this parameter from its default value of 64KB, except possibly to save memory.

15.4.4.8. TCP/IP Connections Using Direct Connections

Setting up a cluster using direct connections between data nodes requires specifying explicitly the crossover IP addresses of the data nodes so connected in the `[TCP]` section of the cluster `config.ini` file.

In the following example, we envision a cluster with at least four hosts, one each for a management server, an SQL node, and two data nodes. The cluster as a whole resides on the `172.23.72.*` subnet of a LAN. In addition to the usual network connections, the two data nodes are connected directly using a standard crossover cable, and communicate with one another directly using IP addresses in the

1.1.0.* address range as shown:

```
# Management Server
[NDB_MGMD]
Id=1
HostName=172.23.72.20

# SQL Node
[MYSQLD]
Id=2
HostName=172.23.72.21

# Data Nodes
[NDBD]
Id=3
HostName=172.23.72.22

[NDBD]
Id=4
HostName=172.23.72.23

# TCP/IP Connections
[TCP]
NodeId1=3
NodeId2=4
HostName1=1.1.0.1
HostName2=1.1.0.2
```

The `HostName N` parameter, where N is an integer, is used only when specifying direct TCP/IP connections.

The use of direct connections between data nodes can improve the cluster's overall efficiency by allowing the data nodes to bypass an Ethernet device such as a switch, hub, or router, thus cutting down on the cluster's latency. It is important to note that to take the best advantage of direct connections in this fashion with more than two data nodes, you must have a direct connection between each data node and every other data node in the same node group.

15.4.4.9. Shared-Memory Connections

MySQL Cluster attempts to use the shared memory transporter and configure it automatically where possible. [SHM] sections in the `config.ini` file explicitly define shared-memory connections between nodes in the cluster. When explicitly defining shared memory as the connection method, it is necessary to define at least `NodeId1`, `NodeId2` and `ShmKey`. All other parameters have default values that should work well in most cases.

Important: *SHM functionality is considered experimental only.* It is not officially supported in any MySQL release series up to and including 5.1. This means that you must determine for yourself or by using our free resources (forums, mailing lists) whether it can be made to work correctly in your specific case.

- `NodeId1`, `NodeId2`

To identify a connection between two nodes it is necessary to provide node identifiers for each of them, as `NodeId1` and `NodeId2`.
- `ShmKey`

When setting up shared memory segments, a node ID, expressed as an integer, is used to identify uniquely the shared memory segment to use for the communication. There is no default value.
- `ShmSize`

Each SHM connection has a shared memory segment where messages between nodes are placed by the sender and read by the reader. The size of this segment is defined by `ShmSize`. The default value is 1MB.

- `SendSignalId`

To retrace the path of a distributed message, it is necessary to provide each message with a unique identifier. Setting this parameter to `Y` causes these message IDs to be transported over the network as well. This feature is disabled by default in production builds, and enabled in `-debug` builds.

- `Checksum`

This parameter is a boolean (`Y/N`) parameter which is disabled by default. When it is enabled, checksums for all messages are calculated before being placed in the send buffer.

This feature prevents messages from being corrupted while waiting in the send buffer. It also serves as a check against data being corrupted during transport.

15.4.4.10. SCI Transport Connections

[`SCI`] sections in the `config.ini` file explicitly define SCI (Scalable Coherent Interface) connections between cluster nodes. Using SCI transporters in MySQL Cluster is supported only when the MySQL-Max binaries are built using `--with-ndb-sci=/your/path/to/SCI`. The `path` should point to a directory that contains at a minimum `lib` and `include` directories containing SISI libraries and header files. (See [Section 15.12, “Using High-Speed Interconnects with MySQL Cluster”](#) for more information about SCI.)

In addition, SCI requires specialized hardware.

It is strongly recommended to use SCI Transporters only for communication between `ndbd` processes. Note also that using SCI Transporters means that the `ndbd` processes never sleep. For this reason, SCI Transporters should be used only on machines having at least two CPUs dedicated for use by `ndbd` processes. There should be at least one CPU per `ndbd` process, with at least one CPU left in reserve to handle operating system activities.

- `NodeId1, NodeId2`

To identify a connection between two nodes it is necessary to provide node identifiers for each of them, as `NodeId1` and `NodeId2`.

- `Host1SciId0`

This identifies the SCI node ID on the first Cluster node (identified by `NodeId1`).

- `Host1SciId1`

It is possible to set up SCI Transporters for failover between two SCI cards which then should use separate networks between the nodes. This identifies the node ID and the second SCI card to be used on the first node.

- `Host2SciId0`

This identifies the SCI node ID on the second Cluster node (identified by `NodeId2`).

- `Host2SciId1`

When using two SCI cards to provide failover, this parameter identifies the second SCI card to be used on the second node.

- `SharedBufferSize`

Each SCI transporter has a shared memory segment used for communication between the two nodes. Setting the size of this segment to the default value of 1MB should be sufficient for most applications. Using a smaller value can lead to problems when performing many parallel inserts; if the shared buffer is too small, this can also result in a crash of the `ndbd` process.

- `SendLimit`

A small buffer in front of the SCI media stores messages before transmitting them over the SCI network. By default, this is set to 8KB. Our benchmarks show that performance is best at 64KB but 16KB reaches within a few percent of this, and there was little if any advantage to increasing it beyond 8KB.

- `SendSignalId`

To trace a distributed message it is necessary to identify each message uniquely. When this parameter is set to `Y`, message IDs are transported over the network. This feature is disabled by default in production builds, and enabled in `-debug` builds.

- `Checksum`

This parameter is a boolean value, and is disabled by default. When `Checksum` is enabled, checksums are calculated for all messages before they are placed in the send buffer. This feature prevents messages from being corrupted while waiting in the send buffer. It also serves as a check against data being corrupted during transport.

15.4.5. Overview of Cluster Configuration Parameters

The next three sections provide summary tables of MySQL Cluster configuration parameters used in the `config.ini` file to govern the cluster's functioning. Each table lists the parameters for one of the Cluster node process types (`ndbd`, `ndb_mgmd`, and `mysqld`), and includes the parameter's type as well as its default, minimum, and maximum values as applicable.

It is also stated what type of restart is required (node restart or system restart) — and whether the restart must be done with `--initial` — to change the value of a given configuration parameter. This information is provided in each table's **Restart Type** column, which contains one of the values shown in this list:

- `N`: Node Restart
- `IN`: Initial Node Restart
- `S`: System Restart

- **IS**: Initial System Restart

When performing a node restart or an initial node restart, all of the cluster's data nodes must be restarted in turn (also referred to as a *rolling restart*). It is possible to update cluster configuration parameters marked **N** or **IN** online — that is, without shutting down the cluster — in this fashion. An initial node restart requires restarting each `ndbd` process with the `--initial` option.

A system restart requires a complete shutdown and restart of the entire cluster. An initial system restart requires taking a backup of the cluster, wiping the cluster filesystem after shutdown, and then restoring from the backup following the restart.

In any cluster restart, all of the cluster's management servers must be restarted in order for them to read the updated configuration parameter values.

Important: Values for numeric cluster parameters can generally be increased without any problems, although it is advisable to do so progressively, making such adjustments in relatively small increments. However, decreasing the values of such parameters — particularly those relating to memory usage and disk space — is not to be undertaken lightly, and it is recommended that you do so only following careful planning and testing. In addition, it is generally the case that parameters relating to memory and disk usage which can be raised using a simple node restart require an initial node restart to be lowered.

Because some of these parameters can be used for configuring more than one type of cluster node, they may appear in more than one of the tables.

(Note that `4294967039` — which often appears as a maximum value in these tables — is equal to $2^{32} - 2^8 - 1$.)

15.4.5.1. Data Node Configuration Parameters

The following table provides information about parameters used in the `[NDBD]` or `[NDB_DEFAULT]` sections of a `config.ini` file for configuring MySQL Cluster data nodes. For detailed descriptions and other additional information about each of these parameters, see [Section 15.4.4.5, “Defining Data Nodes”](#).

Restart Type Column Values

- **N**: Node Restart
- **IN**: Initial Node Restart
- **S**: System Restart
- **IS**: Initial System Restart

See [Section 15.4.5, “Overview of Cluster Configuration Parameters”](#), for additional explanations of these abbreviations.

Parameter Name	Type/ Units	Default Value	Minimum Value	Maximum Value	Restart Type

15.4.5.2. Management Node Configuration Parameters

The following table provides information about parameters used in the [\[NDB_MGMD\]](#) or [\[MGM\]](#) sections of a `config.ini` file for configuring MySQL Cluster management nodes. For detailed descriptions and other additional information about each of these parameters, see [Section 15.4.4.4, “Defining the Management Server”](#).

Restart Type Column Values

- **N**: Node Restart
- **IN**: Initial Node Restart
- **S**: System Restart
- **IS**: Initial System Restart

See [Section 15.4.5, “Overview of Cluster Configuration Parameters”](#), for additional explanations of these abbreviations.

Parameter Name	Type/ Units	Default Value	Minimum Value	Maximum Value	Restart Type
ArbitrationDelay	milli-seconds	0	0	4294967039	N
ArbitrationRank	integer	1	0	2	N
DataDir	string	N/A	N/A	N/A	IN
ExecuteOnComputer	integer				
HostName	string	<code>localhost</code>	N/A	N/A	IN
Id	integer	<i>None</i>	1	63	IN
LogDestination	CONSOLE, SYSLLOG, or FILE	CONSOLE	N/A	N/A	N

15.4.5.3. SQL Node and API Node Configuration Parameters

The following table provides information about parameters used in the [\[SQL\]](#) and [\[API\]](#) sections of a `config.ini` file for configuring MySQL Cluster SQL nodes and API nodes. For detailed descriptions and other additional information about each of these parameters, see [Section 15.4.4.6, “Defining SQL](#)

and Other API Nodes”.

Restart Type Column Values

- **N**: Node Restart
- **IN**: Initial Node Restart
- **S**: System Restart
- **IS**: Initial System Restart

See [Section 15.4.5, “Overview of Cluster Configuration Parameters”](#), for additional explanations of these abbreviations.

Parameter Name	Type/Units	Default Value	Minimum Value	Maximum Value	Restart Type
ArbitrationDelay	mil- li- sec onds	0	0	4294967039	N
ArbitrationRank	in- tege r	1	0	2	N
BatchByteSize	byt es	32K	1K	1M	N

HostName	stri ng	<code>localhost</code>	N/A	N/A	IN
Id	in- tege r	<i>None</i>	1	63	IN
MaxScanBatchSize	byt es	256K	32K	16M	N

15.4.6. Configuring Parameters for Local Checkpoints

The parameters discussed in [Logging and Checkpointing](#) and in [Data Memory, Index Memory, and String Memory](#) that are used to configure local checkpoints for a MySQL Cluster do not exist in isolation, but rather are very much interdependent on each other. In this section, we illustrate how these parameters — including [DataMemory](#), [IndexMemory](#), [NoOfDiskPagesToDiskAfterRestartTUP](#), [NoOfDiskPagesToDiskAfterRestartACC](#), and [NoOfFragmentLogFiles](#) — relate to one another in a working Cluster.

In this example, we assume that our application performs the following numbers of types of operations per hour:

- 50000 selects
- 15000 inserts
- 15000 updates
- 15000 deletes

We also make the following assumptions about the data used in the application:

- We are working with a single table having 40 columns.
- Each column can hold up to 32 bytes of data.
- A typical `UPDATE` run by the application affects the values of 5 columns.
- No `NULL` values are inserted by the application.

A good starting point is to determine the amount of time that should elapse between local checkpoints (LCPs). It worth noting that, in the event of a system restart, it takes 40-60 percent of this interval to execute the REDO log — for example, if the time between LCPs is 5 minutes (300 seconds), then it should take 2 to 3 minutes (120 to 180 seconds) for the REDO log to be read.

The maximum amount of data per node can be assumed to be the size of the `DataMemory` parameter. In this example, we assume that this is 2 GB. The `NoOfDiskPagesToDiskAfterRestartTUP` parameter represents the amount of data to be checkpointed per unit time — however, this parameter is actually expressed as the number of 8K memory pages to be checkpointed per 100 milliseconds. 2 GB per 300 seconds is approximately 6.8 MB per second, or 700 KB per 100 milliseconds, which works out to roughly 85 pages per 100 milliseconds.

Similarly, we can calculate `NoOfDiskPagesToDiskAfterRestartACC` in terms of the time for local checkpoints and the amount of memory required for indexes — that is, the `IndexMemory`. Assuming that we allow 512 MB for indexes, this works out to approximately 20 8-KB pages per 100 milliseconds for this parameter.

Next, we need to determine the number of REDO logfiles required — that is, fragment log files — the corresponding parameter being `NoOfFragmentLogFiles`. We need to make sure that there are sufficient REDO logfiles for keeping records for at least 3 local checkpoints. In a production setting, there are always uncertainties — for instance, we cannot be sure that disks always operate at top speed or with maximum throughput. For this reason, it is best to err on the side of caution, so we double our requirement and calculate a number of fragment logfiles which should be enough to keep records covering 6 local checkpoints.

It is also important to remember that the disk also handles writes to the REDO log and UNDO log, so if you find that the amount of data being written to disk as determined by the values of `NoOfDiskPagesToDiskAfterRestartACC` and `NoOfDiskPagesToDiskAfterRestartTUP` is approaching the amount of disk bandwidth available, you may wish to increase the time between local checkpoints.

Given 5 minutes (300 seconds) per local checkpoint, this means that we need to support writing log records at maximum speed for $6 * 300 = 1800$ seconds. The size of a REDO log record is 72 bytes plus 4 bytes per updated column value plus the maximum size of the updated column, and there is one REDO

log record for each table record updated in a transaction, on each node where the data reside. Using the numbers of operations set out previously in this section, we derive the following:

- 50000 select operations per hour yields 0 log records (and thus 0 bytes), since `SELECT` statements are not recorded in the REDO log.
- 15000 `DELETE` statements per hour is approximately 5 delete operations per second. (Since we wish to be conservative in our estimate, we round up here and in the following calculations.) No columns are updated by deletes, so these statements consume only 5 operations * 72 bytes per operation = 360 bytes per second.
- 15000 `UPDATE` statements per hour is roughly the same as 5 updates per second. Each update uses 72 bytes, plus 4 bytes per column * 5 columns updated, plus 32 bytes per column * 5 columns — this works out to $72 + 20 + 160 = 252$ bytes per operation, and multiplying this by 5 operation per second yields 1260 bytes per second.
- 15000 `INSERT` statements per hour is equivalent to 5 insert operations per second. Each insert requires REDO log space of 72 bytes, plus 4 bytes per record * 40 columns, plus 32 bytes per column * 40 columns, which is $72 + 160 + 1280 = 1512$ bytes per operation. This times 5 operations per second yields 7560 bytes per second.

So the total number of REDO log bytes being written per second is approximately $0 + 360 + 1260 + 7560 = 9180$ bytes. Multiplied by 1800 seconds, this yields 16524000 bytes required for REDO logging, or approximately 15.75 MB. The unit used for `NoOfFragmentLogFiles` represents a set of 4 16-MB logfiles — that is, 64 MB. Thus, the minimum value (3) for this parameter is sufficient for the scenario envisioned in this example, since 3 times 64 = 192 MB, or about 12 times what is required; the default value of 8 (or 512 MB) is more than ample in this case.

A copy of each altered table record is kept in the UNDO log. In the scenario discussed above, the UNDO log would not require any more space than what is provided by the default settings. However, given the size of disks, it is sensible to allocate at least 1 GB for it.

15.5. Upgrading and Downgrading MySQL Cluster

This portion of the MySQL Cluster chapter covers upgrading and downgrading a MySQL Cluster from one MySQL release to another. It discusses different types of Cluster upgrades and downgrades, and provides a Cluster upgrade/downgrade compatibility matrix (see [Section 15.5.2, “Cluster Upgrade and Downgrade Compatibility”](#)).

Important: You are expected already to be familiar with installing and configuring a MySQL Cluster prior to attempting an upgrade or downgrade. See [Section 15.4, “MySQL Cluster Configuration”](#).

This section remains in development, and continues to be updated and expanded.

15.5.1. Performing a Rolling Restart of the Cluster

This section discusses how to perform a *rolling restart* of a MySQL Cluster installation, so called because it involves stopping and starting (or restarting) each node in turn, so that the cluster itself remains operational. This is often done as part of a *rolling upgrade* or *rolling downgrade*, where high availability of the cluster is mandatory and no downtime of the cluster as a whole is permissible. Where we refer to upgrades, the information provided here also generally applies to downgrades as well.

There are a number of reasons why a rolling restart might be desirable:

- **Cluster Configuration Change:** To make a change in the cluster's configuration, such as adding an SQL node to the cluster, or setting a configuration parameter to a new value.
- **Cluster Software Upgrade/Downgrade:** To upgrade the cluster to a newer version of the MySQL Cluster software (or to downgrade it to an older version). This is usually referred to as a “rolling upgrade” (or “rolling downgrade”, when reverting to an older version of MySQL Cluster).
- **Change on Node Host:** To make changes in the hardware or operating system on which one or more cluster nodes are running
- **Cluster Reset:** To reset the cluster because it has reached an undesirable state
- **Freeing of Resources:** To allow memory allocated to a table by successive `INSERT` and `DELETE` operations to be freed for re-use by other Cluster tables

The process for performing a rolling restart may be generalised as follows:

1. Stop, reconfigure, then restart each cluster management node (`ndb_mgmd` process) in turn
2. Stop, reconfigure, then restart each cluster data node (`ndbd` process) in turn
3. Stop, reconfigure, then restart each cluster SQL node (`mysqld` process) in turn

The specifics for implementing a particular rolling upgrade depend upon the actual changes being made. A more detailed view of the process is presented in the table shown here:

In the previous table, **Stop** and **Start** steps indicate that the process must be stopped completely using a shell command (such as `kill` on most Unix systems) or the management client `STOP` command, then started again from a system shell by invoking the `ndbd` or `ndb_mgmd` executable as appropriate. **Restart** indicates the process may be restarted using the `ndb_mgm` management client `RESTART` command.

15.5.2. Cluster Upgrade and Downgrade Compatibility

This section provides information regarding Cluster software and table file compatibility between differing versions of the MySQL Server for purposes of performing upgrades and downgrades.

Important: Only compatibility between MySQL versions with regard to `NDB Cluster` is taken into account in this section, and there are likely other issues to be considered. *As with any other MySQL software upgrade or downgrade, you are strongly encouraged to review the relevant portions of the MySQL Manual for the MySQL versions from which and to which you intend to migrate, before attempting an upgrade or downgrade of the MySQL Cluster software.* See [Section 2.11, “Upgrading MySQL”](#).

The following table shows Cluster upgrade and downgrade compatibility between different versions of the MySQL Server.

Notes:

- **4.1 Series:**

You cannot upgrade directly from 4.1.8 to 4.1.10 (or newer); you must first upgrade from 4.1.8 to 4.1.9, then upgrade to 4.1.10. Similarly, you cannot downgrade directly from 4.1.10 (or newer) to 4.1.8; you must first downgrade from 4.1.10 to 4.1.9, then downgrade from 4.1.9 to 4.1.8.

If you wish to upgrade a MySQL Cluster to 4.1.15, you must upgrade to 4.1.14 first, and you must upgrade to 4.1.15 before upgrading to 4.1.16 or newer.

Cluster downgrades from 4.1.15 to 4.1.14 (or earlier versions) are not supported.

Cluster upgrades from MySQL Server versions previous to 4.1.8 are not supported; when upgrading from these, you must dump all **NDB** tables, install the new version of the software, and then reload the tables from the dump.

- **5.0 Series:**

MySQL 5.0.2 was the first public release in this series.

Cluster downgrades from MySQL 5.0 to MySQL 4.1 are not supported.

Cluster downgrades from 5.0.12 to 5.0.11 (or earlier) are not supported.

You cannot restore with `ndb_restore` to a MySQL 5.0 Cluster using a backup made from a Cluster running MySQL 5.1. You must use `mysqldump` in such cases.

There was no public release for MySQL 5.0.23.

- **5.1 Series:**

MySQL 5.1.3 was the first public release in this series.

You cannot downgrade a MySQL 5.1.6 or later Cluster using Disk Data tables to MySQL 5.1.5 or earlier unless you convert all such tables to in-memory Cluster tables first.

MySQL 5.1.8 and MySQL 5.1.10 were not released.

Online cluster upgrades and downgrades between MySQL 5.1.11 (or an earlier version) and 5.1.12 (or a later version) are not possible due to major changes in the cluster filesystem. In such cases, you must perform a backup or dump, upgrade (or downgrade) the software, start each data node with `-initial`, and then restore from the backup or dump. You can use **NDB** backup/restore or `mysqldump` for this purpose.

15.6. Process Management in MySQL Cluster

Understanding how to manage MySQL Cluster requires a knowledge of four essential processes. In the next few sections of this chapter, we cover the roles played by these processes in a cluster, how to use them, and what startup options are available for each of them:

- [Section 15.6.1, “MySQL Server Process Usage for MySQL Cluster”](#)
- [Section 15.6.2, “ndbd, the Storage Engine Node Process”](#)
- [Section 15.6.3, “ndb_mgmd, the Management Server Process”](#)

- [Section 15.6.4, “ndb_mgm, the Management Client Process”](#)

15.6.1. MySQL Server Process Usage for MySQL Cluster

`mysqld` is the traditional MySQL server process. To be used with MySQL Cluster, `mysqld` needs to be built with support for the `NDB Cluster` storage engine, as it is in the precompiled binaries available from <http://dev.mysql.com/downloads/>. If you build MySQL from source, you must invoke `configure` with the `--with-ndbcluster` option to enable `NDB Cluster` storage engine support.

If the `mysqld` binary has been built with Cluster support, the `NDB Cluster` storage engine is still disabled by default. You can use either of two possible options to enable this engine:

- Use `--ndbcluster` as a startup option on the command line when starting `mysqld`.
- Insert a line containing `ndbcluster` in the `[mysqld]` section of your `my.cnf` file.

An easy way to verify that your server is running with the `NDB Cluster` storage engine enabled is to issue the `SHOW ENGINES` statement in the MySQL Monitor (`mysql`). You should see the value `YES` as the `Support` value in the row for `NDBCLUSTER`. If you see `NO` in this row or if there is no such row displayed in the output, you are not running an `NDB-enabled` version of MySQL. If you see `DISABLED` in this row, you need to enable it in either one of the two ways just described.

To read cluster configuration data, the MySQL server requires at a minimum three pieces of information:

- The MySQL server's own cluster node ID
- The hostname or IP address for the management server (MGM node)
- The number of the TCP/IP port on which it can connect to the management server

Node IDs can be allocated dynamically, so it is not strictly necessary to specify them explicitly.

The `mysqld` parameter `ndb-connectstring` is used to specify the connectstring either on the command line when starting `mysqld` or in `my.cnf`. The connectstring contains the hostname or IP address where the management server can be found, as well as the TCP/IP port it uses.

In the following example, `ndb_mgmd.mysql.com` is the host where the management server resides, and the management server listens for cluster messages on port 1186:

```
shell> mysqld --ndb-connectstring=ndb_mgmd.mysql.com:1186
```

See [Section 15.4.4.2, “The Cluster connectstring”](#), for more information on connectstrings.

Given this information, the MySQL server will be a full participant in the cluster. (We sometimes refer to a `mysqld` process running in this manner as an SQL node.) It will be fully aware of all cluster data nodes as well as their status, and will establish connections to all data nodes. In this case, it is able to use any data node as a transaction coordinator and to read and update node data.

You can see in the `mysql` client whether a MySQL server is connected to the cluster using `SHOW PROCESSLIST`. If the MySQL server is connected to the cluster, and you have the `PROCESS` privilege, then the first row of the output is as shown here:

```
mysql> SHOW PROCESSLIST \G
```

```

***** 1. row *****
  Id: 1
  User: system user
  Host:
  db:
Command: Daemon
  Time: 1
  State: Waiting for event from ndbcluster
  Info: NULL

```

15.6.2. `ndbd`, the Storage Engine Node Process

`ndbd` is the process that is used to handle all the data in tables using the NDB Cluster storage engine. This is the process that empowers a data node to accomplish distributed transaction handling, node recovery, checkpointing to disk, online backup, and related tasks.

In a MySQL Cluster, a set of `ndbd` processes cooperate in handling data. These processes can execute on the same computer (host) or on different computers. The correspondences between data nodes and Cluster hosts is completely configurable.

`ndbd` generates a set of log files which are placed in the directory specified by `DataDir` in the `config.ini` configuration file. These log files are listed below. Note that `node_id` represents the node's unique identifier. For example, `ndb_2_error.log` is the error log generated by the data node whose node ID is 2.

- `ndb_node_id_error.log` is a file containing records of all crashes which the referenced `ndbd` process has encountered. Each record in this file contains a brief error string and a reference to a trace file for this crash. A typical entry in this file might appear as shown here:

```

Date/Time: Saturday 30 July 2004 - 00:20:01
Type of error: error
Message: Internal program error (failed ndbrequire)
Fault ID: 2341
Problem data: DbtupFixAlloc.cpp
Object of reference: DBTUP (Line: 173)
ProgramName: NDB Kernel
ProcessID: 14909
TraceFile: ndb_2_trace.log.2
***EOM***

```

Note: *It is very important to be aware that the last entry in the error log file is not necessarily the newest one* (nor is it likely to be). Entries in the error log are *not* listed in chronological order; rather, they correspond to the order of the trace files as determined in the `ndb_node_id_trace.log.next` file (see below). Error log entries are thus overwritten in a cyclical and not sequential fashion.

- `ndb_node_id_trace.log.trace_id` is a trace file describing exactly what happened just before the error occurred. This information is useful for analysis by the MySQL Cluster development team.

It is possible to configure the number of these trace files that will be created before old files are overwritten. `trace_id` is a number which is incremented for each successive trace file.

- `ndb_node_id_trace.log.next` is the file that keeps track of the next trace file number to be assigned.
- `ndb_node_id_out.log` is a file containing any data output by the `ndbd` process. This file is created only if `ndbd` is started as a daemon, which is the default behavior.

- `ndb_node_id.pid` is a file containing the process ID of the `ndbd` process when started as a daemon. It also functions as a lock file to avoid the starting of nodes with the same identifier.
- `ndb_node_id_signal.log` is a file used only in debug versions of `ndbd`, where it is possible to trace all incoming, outgoing, and internal messages with their data in the `ndbd` process.

It is recommended not to use a directory mounted through NFS because in some environments this can cause problems whereby the lock on the `.pid` file remains in effect even after the process has terminated.

To start `ndbd`, it may also be necessary to specify the hostname of the management server and the port on which it is listening. Optionally, one may also specify the node ID that the process is to use.

```
shell> ndbd --connect-string="nodeid=2;host=ndb_mgmd.mysql.com:1186"
```

See [Section 15.4.4.2, “The Cluster connectstring”](#), for additional information about this issue. [Section 15.6.5, “Command Options for MySQL Cluster Processes”](#), describes other options for `ndbd`.

When `ndbd` starts, it actually initiates two processes. The first of these is called the “angel process”; its only job is to discover when the execution process has been completed, and then to restart the `ndbd` process if it is configured to do so. Thus, if you attempt to kill `ndbd` via the Unix `kill` command, it is necessary to kill both processes, beginning with the angel process. The preferred method of terminating an `ndbd` process is to use the management client and stop the process from there.

The execution process uses one thread for reading, writing, and scanning data, as well as all other activities. This thread is implemented asynchronously so that it can easily handle thousands of concurrent activities. In addition, a watch-dog thread supervises the execution thread to make sure that it does not hang in an endless loop. A pool of threads handles file I/O, with each thread able to handle one open file. Threads can also be used for transporter connections by the transporters in the `ndbd` process. In a multi-processor system performing a large number of operations (including updates), the `ndbd` process can consume up to 2 CPUs if permitted to do so.

For a machine with many CPUs it is possible to use several `ndbd` processes which belong to different node groups; however, such a configuration is still considered experimental and is not supported for MySQL 5.1 in a production setting. See [Section 15.13, “Known Limitations of MySQL Cluster”](#).

15.6.3. `ndb_mgmd`, the Management Server Process

The management server is the process that reads the cluster configuration file and distributes this information to all nodes in the cluster that request it. It also maintains a log of cluster activities. Management clients can connect to the management server and check the cluster's status.

It is not strictly necessary to specify a connectstring when starting the management server. However, if you are using more than one management server, a connectstring should be provided and each node in the cluster should specify its node ID explicitly.

See [Section 15.4.4.2, “The Cluster connectstring”](#), for information about using connectstrings. [Section 15.6.5, “Command Options for MySQL Cluster Processes”](#), describes other options for `ndb_mgmd`.

The following files are created or used by `ndb_mgmd` in its starting directory, and are placed in the `DataDir` as specified in the `config.ini` configuration file. In the list that follows, `node_id` is the unique node identifier.

- `config.ini` is the configuration file for the cluster as a whole. This file is created by the user and

read by the management server. [Section 15.4, “MySQL Cluster Configuration”](#), discusses how to set up this file.

- `ndb_node_id_cluster.log` is the cluster events log file. Examples of such events include checkpoint startup and completion, node startup events, node failures, and levels of memory usage. A complete listing of cluster events with descriptions may be found in [Section 15.7, “Management of MySQL Cluster”](#).

When the size of the cluster log reaches one million bytes, the file is renamed to `ndb_node_id_cluster.log.seq_id`, where `seq_id` is the sequence number of the cluster log file. (For example: If files with the sequence numbers 1, 2, and 3 already exist, the next log file is named using the number 4.)

- `ndb_node_id_out.log` is the file used for `stdout` and `stderr` when running the management server as a daemon.
- `ndb_node_id.pid` is the process ID file used when running the management server as a daemon.

15.6.4. `ndb_mgm`, the Management Client Process

The management client process is actually not needed to run the cluster. Its value lies in providing a set of commands for checking the cluster's status, starting backups, and performing other administrative functions. The management client accesses the management server using a C API. Advanced users can also employ this API for programming dedicated management processes to perform tasks similar to those performed by `ndb_mgm`.

To start the management client, it is necessary to supply the hostname and port number of the management server:

```
shell> ndb_mgm [host_name [port_num]]
```

For example:

```
shell> ndb_mgm ndb_mgmd.mysql.com 1186
```

The default hostname and port number are `localhost` and 1186, respectively.

Additional information about using `ndb_mgm` can be found in [Section 15.6.5.4, “Command Options for `ndb_mgm`”](#), and [Section 15.7.2, “Commands in the Management Client”](#).

15.6.5. Command Options for MySQL Cluster Processes

All MySQL Cluster executables (except for `mysqld`) take the options described in this section. Users of earlier MySQL Cluster versions should note that some of these options have been changed to make them consistent with one another as well as with `mysqld`. You can use the `--help` option with any MySQL Cluster executable to view a list of the options which it supports.

The following options are common to all MySQL Cluster executables:

- `--help --usage, -?`
Prints a short list with descriptions of the available command options.
- `--connect-string=connect_string, -c connect_string`

`connect_string` sets the connectstring to the management server as a command option.

```
shell> ndbd --connect-string="nodeid=2;host=ndb_mgmd.mysql.com:1186"
```

- `--debug[=options]`

This option can be used only for versions compiled with debugging enabled. It is used to enable output from debug calls in the same manner as for the `mysqld` process.

- `--execute=command, -e command`

Can be used to send a command to a Cluster executable from the system shell. For example, either of the following:

```
shell> ndb_mgm -e "SHOW"
```

or

```
shell> ndb_mgm --execute="SHOW"
```

is equivalent to

```
ndb_mgm> SHOW
```

This is analogous to how the `--execute` or `-e` option works with the `mysql` command-line client. See [Section 4.3.1, “Using Options on the Command Line”](#).

- `--version, -V`

Prints the MySQL Cluster version number of the executable. The version number is relevant because not all versions can be used together, and the MySQL Cluster startup process verifies that the versions of the binaries being used can co-exist in the same cluster. This is also important when performing an online (rolling) software upgrade or downgrade of MySQL Cluster. (See [Section 15.5.1, “Performing a Rolling Restart of the Cluster”](#)).

The next few sections describe options specific to individual NDB programs.

15.6.5.1. MySQL Cluster-Related Command Options for `mysqld`

- `--ndb-connectstring=connect_string`

When using the `NDB Cluster` storage engine, this option specifies the management server that distributes cluster configuration data.

- `--ndbcluster`

The `NDB Cluster` storage engine is necessary for using MySQL Cluster. If a `mysqld` binary includes support for the `NDB Cluster` storage engine, the engine is disabled by default. Use the `--ndbcluster` option to enable it. Use `--skip-ndbcluster` to explicitly disable the engine.

15.6.5.2. Command Options for `ndbd`

For options common to all NDB programs, see [Section 15.6.5, “Command Options for MySQL Cluster”](#)

Processes”.

- `--daemon, -d`

Instructs `ndbd` to execute as a daemon process. This is the default behavior. `--nodaemon` can be used to prevent the process from running as a daemon.

- `--initial`

Instructs `ndbd` to perform an initial start. An initial start erases any files created for recovery purposes by earlier instances of `ndbd`. It also re-creates recovery log files. Note that on some operating systems this process can take a substantial amount of time.

An `--initial` start is to be used only the very first time that the `ndbd` process is started because it removes all files from the Cluster filesystem and re-creates all REDO log files. The exceptions to this rule are:

- When performing a software upgrade which has changed the contents of any files.
- When restarting the node with a new version of `ndbd`.
- As a measure of last resort when for some reason the node restart or system restart repeatedly fails. In this case, be aware that this node can no longer be used to restore data due to the destruction of the datafiles.

This option does *not* affect either of the following:

- Backup files that have already been created by the affected node
- Cluster Disk Data files (see [Section 15.11, “MySQL Cluster Disk Data Storage”](#)).

It is possible to achieve the same effect by deleting by other means (such as using `rm -r -f`) all files and directories in the data node's `DataDir` — with the possible exception of the `BACKUP` directory in `DataDir`, should you wish to retain any backups that have been created on that data node — and then starting `ndbd` without having to use the `--initial` option. This may be useful when scripting Cluster administrative tasks.

- `--initial-start`

This option is used when performing a partial initial start of the cluster. Each node should be started with this option, as well as `--no-wait-nodes`.

For example, suppose you have a 4-node cluster whose data nodes have the IDs 2, 3, 4, and 5, and you wish to perform a partial initial start using only nodes 2, 4, and 5 — that is, omitting node 3:

```
ndbd --ndbd-nodeid=2 --no-wait-nodes=3 --initial-start
ndbd --ndbd-nodeid=4 --no-wait-nodes=3 --initial-start
ndbd --ndbd-nodeid=5 --no-wait-nodes=3 --initial-start
```

This option was added in MySQL 5.1.9.

- `--nowait-nodes=node_id_1[, node_id_2[, ...]]`

This option takes a list of data nodes which for which the cluster will not wait for before starting.

This can be used to start the cluster in a partitioned state. For example, to start the cluster with only half of the data nodes (nodes 2, 3, 4, and 5) running in a 4-node cluster, you can start each `ndbd` process with `--nowait-nodes=3,5`. In this case, the cluster starts as soon as nodes 2 and 4 connect, and does *not* wait `StartPartitionedTimeout` milliseconds for nodes 3 and 5 to connect

as it would otherwise.

If you wanted to start up the same cluster as in the previous example without one `ndbd` — say, for example, that the host machine for node 3 has suffered a hardware failure — then start nodes 2, 4, and 5 with `--no-wait-nodes=3`. Then the cluster will start as soon as nodes 2, 4, and 5 connect and will not wait for node 3 to start.

This option was added in MySQL 5.1.9.

- `--nodaemon`

Instructs `ndbd` not to start as a daemon process. This is useful when `ndbd` is being debugged and you want output to be redirected to the screen.

- `--nostart, -n`

Instructs `ndbd` not to start automatically. When this option is used, `ndbd` connects to the management server, obtains configuration data from it, and initializes communication objects. However, it does not actually start the execution engine until specifically requested to do so by the management server. This can be accomplished by issuing the proper `START` command in the management client (see [Section 15.7.2, “Commands in the Management Client”](#)).

15.6.5.3. Command Options for `ndb_mgmd`

For options common to NDB programs, see [Section 15.6.5, “Command Options for MySQL Cluster Processes”](#).

- `--config-file=filename, -f filename`

Instructs the management server as to which file it should use for its configuration file. This option must be specified. The filename defaults to `config.ini`.

Note: This option also can be given as `-c file_name`, but this shortcut is obsolete and should *not* be used in new installations.

- `--daemon, -d`

Instructs `ndb_mgmd` to start as a daemon process. This is the default behavior.

- `--nodaemon`

Instructs `ndb_mgmd` not to start as a daemon process.

15.6.5.4. Command Options for `ndb_mgm`

For options common to NDB programs, see [Section 15.6.5, “Command Options for MySQL Cluster Processes”](#).

- `--try-reconnect=number`

If the connection to the management server is broken, the node tries to reconnect to it every 5 seconds until it succeeds. By using this option, it is possible to limit the number of attempts to `number` before giving up and reporting an error instead.

15.7. Management of MySQL Cluster

Managing a MySQL Cluster involves a number of tasks, the first of which is to configure and start MySQL Cluster. This is covered in [Section 15.4, “MySQL Cluster Configuration”](#), and [Section 15.6, “Process Management in MySQL Cluster”](#).

The following sections cover the management of a running MySQL Cluster.

There are essentially two methods of actively managing a running MySQL Cluster. The first of these is through the use of commands entered into the management client whereby cluster status can be checked, log levels changed, backups started and stopped, and nodes stopped and started. The second method involves studying the contents of the cluster log `ndb_node_id_cluster.log`; this is usually found in the management server's `DataDir` directory, but this location can be overridden using the `LogDestination` option — see [Section 15.4.4.4, “Defining the Management Server”](#), for details. (Recall that `node_id` represents the unique identifier of the node whose activity is being logged.) The cluster log contains event reports generated by `ndbd`. It is also possible to send cluster log entries to a Unix system log.

15.7.1. MySQL Cluster Startup Phases

This section describes the steps involved when the cluster is started.

There are several different startup types and modes, as shown here:

- **Initial Start:** The cluster starts with a clean filesystem on all data nodes. This occurs either when the cluster started for the very first time, or when it is restarted using the `--initial` option.
Note: Disk Data files are not removed when restarting a node using `--initial`.
- **System Restart:** The cluster starts and reads data stored in the data nodes. This occurs when the cluster has been shut down after having been in use, when it is desired for the cluster to resume operations from the point where it left off.
- **Node Restart:** This is the online restart of a cluster node while the cluster itself is running.
- **Initial Node Restart:** This is the same as a node restart, except that the node is reinitialized and started with a clean filesystem.

Prior to startup, each data node (`ndbd` process) must be initialized. Initialization consists of the following steps:

1. Obtain a Node ID.
2. Fetch configuration data.
3. Allocate ports to be used for inter-node communications.
4. Allocate memory according to settings obtained from the configuration file.

When a data node or SQL node first connects to the management node, it reserves a cluster node ID. To make sure that no other node allocates the same node ID, this ID is retained until the node has managed to connect to the cluster and at least one `ndbd` reports that this node is connected. This retention of the node ID is guarded by the connection between the node in question and `ndb_mgmd`.

Normally, in the event of a problem with the node, the node disconnects from the management server,

the socket used for the connection is closed, and the reserved node ID is freed. However, if a node is disconnected abruptly — for example, due to a hardware failure in one of the cluster hosts, or because of network issues — the normal closing of the socket by the operating system may not take place. In this case, the node ID continues to be reserved and not released until a TCP timeout occurs 10 or so minutes later.

To take care of this problem, you can use `PURGE STALE SESSIONS`. Running this statement forces all reserved node IDs to be checked; any that are not being used by nodes actually connected to the cluster are then freed.

Beginning with MySQL 5.1.11, timeout handling of node ID assignments is implemented. This performs the ID usage checks automatically after approximately 20 seconds, so that `PURGE STALE SESSIONS` should no longer be necessary in a normal Cluster start.

After each data node has been initialized, the cluster startup process can proceed. The stages which the cluster goes through during this process are listed here:

- **Stage 0**

Clear the cluster filesystem. This stage occurs *only* if the cluster was started with the `--initial` option.

- **Stage 1**

This stage sets up Cluster connections, establishes inter-node communications, and starts Cluster heartbeats.

Note: When one or more nodes hang in Phase 1 while the remaining node or nodes hang in Phase 2, this often indicates network problems. One possible cause of such issues is one or more cluster hosts having multiple network interfaces. Another common source of problems causing this condition is the blocking of TCP/IP ports needed for communications between cluster nodes. In the latter case, this is often due to a misconfigured firewall.

- **Stage 2**

The arbitrator node is elected. If this is a system restart, the cluster determines the latest restorable global checkpoint.

- **Stage 3**

This stage initializes a number of internal cluster variables.

- **Stage 4**

For an initial start or initial node restart, the redo log files are created. The number of these files is equal to `NoOfFragmentLogFiles`.

For a system restart:

- Read schema or schemas.
- Read data from the local checkpoint and undo logs.
- Apply all redo information until the latest restorable global checkpoint has been reached.

For a node restart, find the tail of the redo log.

- **Stage 5**

If this is an initial start, create the `SYSTAB_0` and `NDB$EVENTS` internal system tables.

For a node restart or an initial node restart:

1. The node is included in transaction handling operations.
2. The node schema is compared with that of the master and synchronized with it.
3. Synchronize data received in the form of `INSERT` from the other data nodes in this node's node group.
4. In all cases, wait for complete local checkpoint as determined by the arbitrator.

- **Stage 6**

Update internal variables.

- **Stage 7**

Update internal variables.

- **Stage 8**

In a system restart, rebuild all indexes.

- **Stage 9**

Update internal variables.

- **Stage 10**

At this point in a node restart or initial node restart, APIs may connect to the node and begin to receive events.

- **Stage 11**

At this point in a node restart or initial node restart, event delivery is handed over to the node joining the cluster. The newly-joined node takes over responsibility for delivering its primary data to subscribers.

After this process is completed for an initial start or system restart, transaction handling is enabled. For a node restart or initial node restart, completion of the startup process means that the node may now act as a transaction coordinator.

15.7.2. Commands in the Management Client

In addition to the central configuration file, a cluster may also be controlled through a command-line interface available through the management client `ndb_mgm`. This is the primary administrative interface to a running cluster.

Commands for the event logs are given in [Section 15.7.3, “Event Reports Generated in MySQL Cluster”](#); commands for creating backups and restoring from backup are provided in [Section 15.8, “On-line Backup of MySQL Cluster”](#).

The management client has the following basic commands. In the listing that follows, `node_id` denotes either a database node ID or the keyword `ALL`, which indicates that the command should be applied to all of the cluster's data nodes.

- `HELP`
Displays information on all available commands.
- `SHOW`
Displays information on the cluster's status.
Note: In a cluster where multiple management nodes are in use, this command displays information only for data nodes that are actually connected to the current management server.
- `node_id START`
Brings online the data node identified by `node_id` (or all data nodes).
`ALL START` works on all data nodes only, and does not affect management nodes.
Important: To use this command to bring a data node online, the data node must have been started using `ndbd --nostart` or `ndbd -n`.
- `node_id STOP`
Starts the data or management node identified by `node_id`. Note that `ALL STOP` works to start all data nodes only, and does not affect management nodes.
A node affected by this command disconnects from the cluster, and its associated `ndbd` or `ndb_mgmd` process terminates.
- `node_id RESTART [-n] [-i]`
Restarts the data node identified by `node_id` (or all data nodes).
Using the `-i` option with `RESTART` causes the data node to perform an initial restart; that is, the node's filesystem is deleted and recreated. The effect is the same as that obtained from stopping the data node process and then starting it again using `ndbd --initial` from the system shell. Note that backup files and Disk Data files are not removed when this option is used.
Using the `-n` option causes the data node process to be restarted, but the data node is not actually brought online until the appropriate `START` command is issued. The effect of this option is the same as that obtained from stopping the data node and then starting it again using `ndbd --nostart` or `ndbd -n` from the system shell.
- `node_id STATUS`
Displays status information for the data node identified by `node_id` (or for all data nodes).
- `ENTER SINGLE USER MODE node_id`
Enters single user mode, whereby only the MySQL server identified by the node ID `node_id` is allowed to access the database.
- `EXIT SINGLE USER MODE`

Exits single user mode, allowing all SQL nodes (that is, all running `mysqld` processes) to access the database.

- `QUIT, EXIT`

Terminates the management client.

This command does not affect any nodes connected to the cluster.

- `SHUTDOWN`

Shuts down all cluster data nodes and management nodes. To exit the management client after this has been done, use `EXIT` or `QUIT`.

This command does *not* shut down any SQL nodes or API nodes that are connected to the cluster.

15.7.3. Event Reports Generated in MySQL Cluster

In this section, we discuss the types of event logs provided by MySQL Cluster, and the types of events that are logged.

MySQL Cluster provides two types of event log. These are the *cluster log*, which includes events generated by all cluster nodes, and the *node logs*, which are local to each data node.

Output generated by cluster event logging can have multiple destinations including a file, the management server console window, or `syslog`. Output generated by node event logging is written to the data node's console window.

Both types of event logs can be set to log different subsets of events.

Note: The cluster log is the log recommended for most uses because it provides logging information for an entire cluster in a single file. Node logs are intended to be used only during application development, or for debugging application code.

Each reportable event can be distinguished according to three different criteria:

- *Category:* This can be any one of the following values: `STARTUP`, `SHUTDOWN`, `STATISTICS`, `CHECKPOINT`, `NODERESTART`, `CONNECTION`, `ERROR`, or `INFO`.
- *Priority:* This is represented by one of the numbers from 1 to 15 inclusive, where 1 indicates “most important” and 15 “least important.”
- *Severity Level:* This can be any one of the following values: `ALERT`, `CRITICAL`, `ERROR`, `WARNING`, `INFO`, or `DEBUG`.

Both the cluster log and the node log can be filtered on these properties.

15.7.3.1. Logging Management Commands

The following management commands are related to the cluster log:

- `CLUSTERLOG ON`

Turns the cluster log on.

- `CLUSTERLOG OFF`

Turns the cluster log off.

- `CLUSTERLOG INFO`

Provides information about cluster log settings.

- `node_id CLUSTERLOG category=threshold`

Logs *category* events with priority less than or equal to *threshold* in the cluster log.

- `CLUSTERLOG FILTER severity_level`

Toggles cluster logging of events of the specified *severity_level*.

The following table describes the default setting (for all data nodes) of the cluster log category threshold. If an event has a priority with a value lower than or equal to the priority threshold, it is reported in the cluster log.

Note that events are reported per data node, and that the threshold can be set to different values on different nodes.

Category	Default threshold (All data nodes)
STARTUP	7
SHUTDOWN	7
STATISTICS	7
CHECKPOINT	7
NODERESTART	7
CONNECTION	7
ERROR	15
INFO	7

Thresholds are used to filter events within each category. For example, a `STARTUP` event with a priority of 3 is not logged unless the threshold for `STARTUP` is changed to 3 or lower. Only events with priority 3 or lower are sent if the threshold is 3.

The following table shows the event severity levels. (**Note:** These correspond to Unix `syslog` levels, except for `LOG_EMERG` and `LOG_NOTICE`, which are not used or mapped.)

1	ALERT	A condition that should be corrected immediately, such as a corrupted system database
2	CRITICAL	Critical conditions, such as device errors or insufficient resources
3	ERROR	Conditions that should be corrected, such as configuration errors
4	WARNING	Conditions that are not errors, but that might require special handling
5	INFO	Informational messages
6	DEBUG	Debugging messages used for NDB Cluster development

Event severity levels can be turned on or off (using `CLUSTERLOG FILTER` — see above). If a severity level is turned on, then all events with a priority less than or equal to the category thresholds are logged. If the severity level is turned off then no events belonging to that severity level are logged.

15.7.3.2. Log Events

An event report reported in the event logs has the following format:

```
datetime [string] severity -- message
```

For example:

```
09:19:30 2005-07-24 [NDB] INFO -- Node 4 Start phase 4 completed
```

This section discusses all reportable events, ordered by category and severity level within each category.

In the event descriptions, GCP and LCP mean “Global Checkpoint” and “Local Checkpoint,” respectively.

CONNECTION Events

These events are associated with connections between Cluster nodes.

Event	Priority	Severity Level	Description
data nodes connected	8	INFO	Data nodes connected
data nodes disconnected	8	INFO	Data nodes disconnected
Communication closed	8	INFO	SQL node or data node connection closed
Communication opened	8	INFO	SQL node or data node connection opened

CHECKPOINT Events

The logging messages shown here are associated with checkpoints.

Event	Priority	Severity Level	Description
LCP stopped in calc keep GCI	0	ALERT	LCP stopped
Local checkpoint fragment completed	11	INFO	LCP on a fragment has been completed
Global checkpoint completed	10	INFO	GCP finished
Global checkpoint started	9	INFO	Start of GCP: REDO log is written to disk
Local checkpoint completed	8	INFO	LCP completed normally
Local checkpoint started	7	INFO	Start of LCP: data written to disk
Report undo log blocked	7	INFO	UNDO logging blocked; buffer near overflow

STARTUP Events

The following events are generated in response to the startup of a node or of the cluster and of its success or failure. They also provide information relating to the progress of the startup process, including information concerning logging activities.

Event	Priority	Severity Level	Description
Internal start signal received ST-TORRY	15	INFO	Blocks received after completion of restart
Undo records executed	15	INFO	
New REDO log started	10	INFO	GCI keep <i>X</i> , newest restorable GCI <i>Y</i>
New log started	10	INFO	Log part <i>X</i> , start MB <i>Y</i> , stop MB <i>Z</i>
Node has been refused for inclusion in the cluster	8	INFO	Node cannot be included in cluster due to misconfiguration, inability to establish communication, or other problem
data node neighbors	8	INFO	Shows neighboring data nodes
data node start phase <i>X</i> completed	4	INFO	A data node start phase has been completed
Node has been successfully included into the cluster	3	INFO	Displays the node, managing node, and dynamic ID
data node start phases initiated	1	INFO	NDB Cluster nodes starting
data node all start phases completed	1	INFO	NDB Cluster nodes started
data node shutdown initiated	1	INFO	Shutdown of data node has commenced
data node shutdown aborted	1	INFO	Unable to shut down data node normally

NODERESTART Events

The following events are generated when restarting a node and relate to the success or failure of the node restart process.

Event	Priority	Severity Level	Description
Node failure phase completed	8	ALERT	Reports completion of node failure phases
Node has failed, node state was <i>X</i>	8	ALERT	Reports that a node has failed
Report arbitrator results	2	ALERT	<p>There are eight different possible results for arbitration attempts:</p> <ul style="list-style-type: none"> • Arbitration check failed — less than 1/2 nodes left • Arbitration check succeeded — node group majority • Arbitration check failed — missing node group • Network partitioning — arbitration required • Arbitration succeeded — affirmative response from node <i>X</i> • Arbitration failed - negative response from node <i>X</i>

			<ul style="list-style-type: none"> Network partitioning - no arbitrator available Network partitioning - no arbitrator configured
Completed copying a fragment	10	INFO	
Completed copying of dictionary information	8	INFO	
Completed copying distribution information	8	INFO	
Starting to copy fragments	8	INFO	
Completed copying all fragments	8	INFO	
GCP takeover started	7	INFO	
GCP takeover completed	7	INFO	
LCP takeover started	7	INFO	
LCP takeover completed (state = <i>X</i>)	7	INFO	
Report whether an arbitrator is found or not	6	INFO	<p>There are seven different possible outcomes when seeking an arbitrator:</p> <ul style="list-style-type: none"> Management server restarts arbitration thread [state=<i>X</i>] Prepare arbitrator node <i>X</i> [ticket=<i>Y</i>] Receive arbitrator node <i>X</i> [ticket=<i>Y</i>] Started arbitrator node <i>X</i> [ticket=<i>Y</i>] Lost arbitrator node <i>X</i> - process failure [state=<i>Y</i>] Lost arbitrator node <i>X</i> - process exit [state=<i>Y</i>] Lost arbitrator node <i>X</i> <error msg> [state=<i>Y</i>]

STATISTICS Events

The following events are of a statistical nature. They provide information such as numbers of transactions and other operations, amount of data sent or received by individual nodes, and memory usage.

Event	Priority	Severity Level	Description
Report job scheduling statistics	9	INFO	Mean internal job scheduling statistics
Sent number of bytes	9	INFO	Mean number of bytes sent to node <i>X</i>
Received # of bytes	9	INFO	Mean number of bytes received from node <i>X</i>

Report transaction statistics	8	INFO	Numbers of: transactions, commits, reads, simple reads, writes, concurrent operations, attribute information, and aborts
Report operations	8	INFO	Number of operations
Report table create	7	INFO	
Memory usage	5	INFO	Data and index memory usage (80%, 90%, and 100%)

ERROR Events

These events relate to Cluster errors and warnings. The presence of one or more of these generally indicates that a major malfunction or failure has occurred.

Event	Priority	Severity	Description
Dead due to missed heartbeat	8	ALERT	Node <i>X</i> declared “dead” due to missed heartbeat
Transporter errors	2	ERROR	
Transporter warnings	8	WARNING	
Missed heartbeats	8	WARNING	Node <i>X</i> missed heartbeat # <i>Y</i>
General warning events	2	WARNING	

INFO Events

These events provide general information about the state of the cluster and activities associated with Cluster maintenance, such as logging and heartbeat transmission.

Event	Priority	Severity	Description
Sent heartbeat	12	INFO	Heartbeat sent to node <i>X</i>
Create log bytes	11	INFO	Log part, log file, MB
General information events	2	INFO	

15.7.3.3. Using CLUSTERLOG STATISTICS

The NDB management client's `CLUSTERLOG STATISTICS` command can provide a number of useful statistics in its output. The following statistics are reported by the transaction coordinator:

Statistic	Description (Number of...)
<code>Trans. Count</code>	Transactions attempted with this node as coordinator
<code>Commit Count</code>	Transactions committed with this node as coordinator
<code>Read Count</code>	Primary key reads (all)
<code>Simple Read Count</code>	Primary key reads reading the latest committed value
<code>Write Count</code>	Primary key writes (includes all <code>INSERT</code> , <code>UPDATE</code> , and <code>DELETE</code> operations)
<code>AttrInfoCount</code>	Data words used to describe all reads and writes received

Concurrent Operations	All concurrent operations ongoing at the moment the report is taken
Abort Count	Transactions with this node as coordinator that were aborted
Scans	Scans (all)
Range Scans	Index scans

The `ndbd` process has a scheduler that runs in an infinite loop. During each loop scheduler performs the following tasks:

1. Read any incoming messages from sockets into a job buffer.
2. Check whether there are any timed messages to be executed; if so, put these into the job buffer as well.
3. Execute (in a loop) any messages in the job buffer.
4. Send any distributed messages that were generated by executing the messages in the job buffer.
5. Wait for any new incoming messages.

The number of loops executed in the third step is reported as the `Mean Loop Counter`. This statistic increases in size as the utilisation of the TCP/IP buffer improves. You can use this to monitor performance as you add new processes to the cluster.

The `Mean send size` and `Mean receive size` statistics allow you to gauge the efficiency of writes and reads (respectively) between nodes. These values are given in bytes. Higher values mean a lower cost per byte sent or received; the maximum is 64k.

To generate a report of all cluster log statistics, you can use the following command in the `NDB` management client:

```
ndb_mgm> ALL CLUSTERLOG STATISTICS=15
```

15.7.4. Single User Mode

Single user mode allows the database administrator to restrict access to the database system to a single MySQL server (SQL node). When entering single user mode, all connections to all other MySQL servers are closed gracefully and all running transactions are aborted. No new transactions are allowed to start.

Once the cluster has entered single user mode, only the designated SQL node is granted access to the database.

You can use the `ALL STATUS` command to see when the cluster has entered single user mode.

Example:

```
NDB> ENTER SINGLE USER MODE 5
```

After this command has executed and the cluster has entered single user mode, the SQL node whose node ID is `5` becomes the cluster's only permitted user.

The node specified in the preceding command must be a MySQL Server node; An attempt to specify

any other type of node will be rejected.

Note: When the preceding command is invoked, all transactions running on the designated node are aborted, the connection is closed, and the server must be restarted.

The command `EXIT SINGLE USER MODE` changes the state of the cluster's data nodes from single user mode to normal mode. MySQL Servers waiting for a connection (that is, for the cluster to become ready and available), are again permitted to connect. The MySQL Server denoted as the single-user SQL node continues to run (if still connected) during and after the state change.

Example:

```
NDB> EXIT SINGLE USER MODE
```

There are two recommended ways to handle a node failure when running in single user mode:

- Method 1:
 1. Finish all single user mode transactions
 2. Issue the `EXIT SINGLE USER MODE` command
 3. Restart the cluster's data nodes
- Method 2:

Restart database nodes prior to entering single user mode.

15.8. On-line Backup of MySQL Cluster

This section describes how to create a backup and how to restore the database from a backup at a later time.

15.8.1. Cluster Backup Concepts

A backup is a snapshot of the database at a given time. The backup consists of three main parts:

- **Metadata:** the names and definitions of all database tables
- **Table records:** the data actually stored in the database tables at the time that the backup was made
- **Transaction log:** a sequential record telling how and when data was stored in the database

Each of these parts is saved on all nodes participating in the backup. During backup, each node saves these three parts into three files on disk:

- `BACKUP-backup_id.node_idctl`

A control file containing control information and metadata. Each node saves the same table definitions (for all tables in the cluster) to its own version of this file.

- `BACKUP-backup_id-0.node_id.data`

A data file containing the table records, which are saved on a per-fragment basis. That is, different nodes save different fragments during the backup. The file saved by each node starts with a header that states the tables to which the records belong. Following the list of records there is a footer containing a checksum for all records.

- `BACKUP-backup_id.node_id.log`

A log file containing records of committed transactions. Only transactions on tables stored in the backup are stored in the log. Nodes involved in the backup save different records because different nodes host different database fragments.

In the listing above, `backup_id` stands for the backup identifier and `node_id` is the unique identifier for the node creating the file.

15.8.2. Using The Management Client to Create a Backup

Before starting a backup, make sure that the cluster is properly configured for performing one. (See [Section 15.8.4, “Configuration for Cluster Backup”](#).)

Creating a backup using the management client involves the following steps:

1. Start the management client (`ndb_mgm`).
2. Execute the command `START BACKUP`.
3. The management client will reply with the message `Start of backup ordered`. This means that the management client has submitted the request to the cluster, but has not yet received any response.
4. The management client will reply `Backup backup_id started`, where `backup_id` is the unique identifier for this particular backup. (This identifier will also be saved in the cluster log, if it has not been configured otherwise.) This means that the cluster has received and processed the backup request. It does *not* mean that the backup has finished.
5. The management client will signal that the backup is finished with the message `Backup backup_id completed`.

Cluster backups are created by default in the `BACKUP` subdirectory of the `DataDir` on each data node. This can be overridden for one or more data nodes individually, or for all cluster data nodes in the `config.ini` file using the `BackupDataDir` configuration parameter as discussed in [Identifying Data Nodes](#). The backup files created for a backup with a given `backup_id` are stored in a subdirectory named `BACKUP-backup_id` in the backup directory.

To abort a backup that is already in progress:

1. Start the management client.
2. Execute the command `ABORT BACKUP backup_id`. The number `backup_id` is the identifier of the backup that was included in the response of the management client when the backup was started (in the message `Backup backup_id started`).
3. The management client will acknowledge the abort request with `Abort of backup backup_id ordered`; note that it has received no actual response to this request yet.

- After the backup has been aborted, the management client will report `Backup backup_id has been aborted for reason XYZ`. This means that the cluster has terminated the backup and that all files related to this backup have been removed from the cluster filesystem.

It is also possible to abort a backup in progress from the system shell using this command:

```
shell> ndb_mgm -e "ABORT BACKUP backup_id"
```

Note: If there is no backup with ID `backup_id` running when it is aborted, the management client makes no explicit response. However, the fact that an invalid abort command was sent is indicated in the cluster log.

15.8.3. How to Restore a Cluster Backup

The cluster restoration program is implemented as a separate command-line utility `ndb_restore`, which can normally be found in the MySQL `bin` directory. This program reads the files created as a result of the backup and inserts the stored information into the database. `ndb_restore` must be executed once for each set of backup files — that is, once for each data node in the cluster at the time that the backup was created.

Important: In order to use `ndb_restore`, the cluster must be running in single user mode. See [Section 15.7.4, “Single User Mode”](#).

Typical options for this utility are shown here:

```
ndb_restore [-c connectstring] -n node_id [-m] -b backup_id -r /path/to/backup/files
```

The `-c` option is used to specify a connectstring which tells `ndb_restore` where to locate the cluster management server. (See [Section 15.4.4.2, “The Cluster connectstring”](#), for information on connectstrings.) If this option is not used, then `ndb_restore` attempts to connect to a management server on `localhost:1186`. This utility acts as a cluster API node, and so requires a free connection “slot” to connect to the cluster management server. This means that there must be at least one `[API]` section that can be used by it in the cluster `config.ini` file. It is a good idea to keep at least one empty `[API]` section in `config.ini` that is not being used for a MySQL server or for an application for this reason (see [Section 15.4.4.6, “Defining SQL and Other API Nodes”](#)). `ndb_restore` can also employ an unused `[MYSQLD]` section in the `config.ini` file for this purpose.

You can verify that `ndb_restore` is connected to the cluster by using the `SHOW` command in the `ndb_mgm` management client. You can also accomplish this from a system shell, as shown here:

```
shell> ndb_mgm -e "SHOW"
```

`-n` is used to specify the node ID of the data node on which the backups were taken.

The first time you run the `ndb_restore` restoration program, you also need to restore the metadata. In other words, you must re-create the database tables — this can be done by running it with the `-m` option. Note that the cluster should have an empty database when starting to restore a backup. (In other words, you should start `ndbd` with `--initial` prior to performing the restore. You should also remove manually any Disk Data files present in the data node's `DataDir`.)

The `-b` option is used to specify the ID or sequence number of the backup, and is the same number shown by the management client in the `Backup backup_id completed` message displayed upon completion of a backup. (See [Section 15.8.2, “Using The Management Client to Create a Backup”](#).)

The `-r` option is required, and is used to tell `ndb_restore` the directory where it can find the backup files. **Important:** When restoring cluster backups, you must be sure to restore all data nodes from

backups having the same backup ID.

It is possible to restore a backup to a database with a different configuration than it was created from. For example, suppose that a backup with backup ID 12, created in a cluster with two database nodes having the node IDs 2 and 3, is to be restored to a cluster with four nodes. Then `ndb_restore` must be run twice — once for each database node in the cluster where the backup was taken. However, `ndb_restore` cannot always restore backups made from a cluster running one version of MySQL to a cluster running a different MySQL version. See [Section 15.5.2, “Cluster Upgrade and Downgrade Compatibility”](#), for more information.

Note: For rapid restoration, the data may be restored in parallel, provided that there is a sufficient number of cluster connections available. However, the data files must always be applied before the logs.

A complete listing of options available for this program is shown in the following table:

Long Form	Short Form	Description	Default Value
<code>--backup-id</code>	<code>-b</code>	Backup sequence ID	0
<code>--backup_path</code>	<i>None</i>	Path to backup files	<code>./</code>
<code>- -char- acter-sets-dir</code>	<i>None</i>	Specify the directory where character set information can be found	<i>None</i>
<code>--connect, - -connectstring, or - - ndb- connectstring</code>	<code>-c</code> or <code>-C</code>	Set the connectstring in <i>hos</i>	<i>None</i>

		<code>port]</code> format	
<code>--core-file</code>	<i>None</i>	Write a core file in the event of an error	<code>TRUE</code>
<code>--debug</code>	<code>-#</code>	Output debug log	<code>d:t:0,/tmp/ndb_restore.trace</code>
<code>-dont_ignore_sys_tables_0</code>	<code>-f</code>	Do not ignore system table during restore — <i>EXPERIMENTAL; not for production use</i>	<code>FALSE</code>
<code>--help</code> or <code>--usage</code>	<code>-?</code>	Display help message with available options and current values, then exit	[N/A]
<code>--ndb-mgmd-host</code>	<i>None</i>	Set the host and port in <code>host[:port]</code> format for the management server to connect to; this is the same as <code>-connect</code> , <code>--connectstring</code> , or <code>--ndb-connectstring</code> , but without a way to specify the <code>nodeid</code>	<i>None</i>
<code>-ndb-nodegroup-map</code>	<code>-z</code>	Specifies a nodegroup map — <i>Syntax</i> : list of (<code>source_nodegroup</code> , <code>destination_nodegroup</code>)	<i>None</i>
<code>--ndb-nodeid</code>	<i>None</i>	Specify a node ID for the <code>ndb_restore</code> process	<code>0</code>
<code>-ndb-optimized-node-selection</code>	<i>None</i>	Optimize selection of nodes for transactions	<code>TRUE</code>
<code>--ndb-shm</code>	<i>None</i>	Use shared memory connections when available	<code>FALSE</code>
<code>-no-restore-disk-objects</code>	<code>-d</code>	Do not restore Disk Data objects such as tablespaces and logfile groups	<code>FALSE</code> (in other words, restore Disk Data objects unless this option is used)
<code>--nodeid</code>	<code>-n</code>	Use backup files from node with the specified ID	<code>0</code>
<code>--parallelism</code>	<code>-p</code>	Set from 1 to 1024 parallel transactions to be used during the restoration process	<code>128</code>
<code>--print</code>	<i>None</i>	Print data and log to <code>stdout</code>	<code>FALSE</code>
<code>--print_data</code>	<i>None</i>	Print data to <code>stdout</code>	<code>FALSE</code>
<code>--print_log</code>	<i>None</i>	Print log to <code>stdout</code>	<code>FALSE</code>
<code>--print_meta</code>	<i>None</i>	Print metadata to <code>stdout</code>	<code>FALSE</code>
<code>--restore_data</code>	<code>-r</code>	Restore data and logs	<code>FALSE</code>
<code>--restore_epoch</code>	<code>-e</code>	Restore epoch data into the status table; the row in the <code>cluster.apply_status</code> having the id <code>0</code> is inserted or updated as appropriate — this is convenient when start-	<code>FALSE</code>

		ing up replication on a MySQL Cluster replication slave	
<code>--restore_meta</code>	<code>-m</code>	Restore table metadata	<code>FALSE</code>
<code>--version</code>	<code>-V</code>	Output version information and exit	[N/A]

15.8.4. Configuration for Cluster Backup

Four configuration parameters are essential for backup:

- `BackupDataBufferSize`
The amount of memory used to buffer data before it is written to disk.
- `BackupLogBufferSize`
The amount of memory used to buffer log records before these are written to disk.
- `BackupMemory`
The total memory allocated in a database node for backups. This should be the sum of the memory allocated for the backup data buffer and the backup log buffer.
- `BackupWriteSize`
The default size of blocks written to disk. This applies for both the backup data buffer and the backup log buffer.
- `BackupMaxWriteSize`
The maximum size of blocks written to disk. This applies for both the backup data buffer and the backup log buffer.

More detailed information about these parameters can be found in [Backup Parameters](#).

15.8.5. Backup Troubleshooting

If an error code is returned when issuing a backup request, the most likely cause is insufficient memory or disk space. You should check that there is enough memory allocated for the backup. **Important:** If you have set `BackupDataBufferSize` and `BackupLogBufferSize` and their sum is greater than 4MB, then you must also set `BackupMemory` as well. See [BackupMemory](#).

You should also make sure that there is sufficient space on the hard drive partition of the backup target.

NDB does not support repeatable reads, which can cause problems with the restoration process. Although the backup process is “hot”, restoring a MySQL Cluster from backup is not a 100% “hot” process. This is due to the fact that, for the duration of the restore process, running transactions get non-repeatable reads from the restored data. This means that the state of the data is inconsistent while the restore is in progress.

15.9. Cluster Utility Programs

This section discusses the MySQL Cluster utility programs that can be found in the `mysql/bin` directory. Each of these — except for `ndb_size.pl` and `ndb_error_reporter` — is a standalone binary that can be used from a system shell, and that does not need to connect to a MySQL server (nor even requires that a MySQL server be connected to the cluster).

These utilities can also serve as examples for writing your own applications using the [NDB API](#). The source code for most of these programs may be found in the `storage/ndb/tools` directory of the MySQL 5.1 tree (see [Section 2.9, “MySQL Installation Using a Source Distribution”](#)). The [NDB API](#) is not covered in this manual; please refer to the [NDB API Guide](#) [<http://dev.mysql.com/doc/ndbapi/en/>] for information about this API.

All of the [NDB](#) utilities are listed here with brief descriptions:

- `ndb_config`: Retrieves Cluster configuration option values.
- `ndb_delete_all`: Deletes all rows from a given table.
- `ndb_desc`: Lists all properties of an [NDB](#) table.
- `ndb_drop_index`: Drops the specified index from an [NDB](#) table.
- `ndb_drop_table`: Drops an [NDB](#) table.
- `ndb_error_reporter`: Can be used to gather information useful for diagnosing problems with the cluster.
- `ndb_mgm`: This is the MySQL Cluster management client, which is discussed in [Section 15.7.2, “Commands in the Management Client”](#).
- `ndb_print_backup_file`: Prints diagnostic information obtained from cluster backup files.
- `ndb_print_schema_file`: Prints diagnostic information obtained from cluster schema files.
- `ndb_print_sys_file`: Prints diagnostic information obtained from cluster system files.
- `ndb_restore`: This utility is used to restore a cluster from backup. See [Section 15.8.3, “How to Restore a Cluster Backup”](#), for more information.
- `ndb_select_all`: Prints all rows from an [NDB](#) table.
- `ndb_select_count`: Gets the number of rows in one or more [NDB](#) tables.
- `ndb_show_tables`: Shows all [NDB](#) tables anywhere in the cluster.
- `ndb_size.pl`: Examines all the tables in a given non-Cluster database and calculates the amount of storage each would require if it were converted to use the [NDB](#) storage engine.
- `ndb_waiter`: Reports on the status of cluster data nodes in a manner similar to that of the management client command `ALL STATUS`.

Most of these utilities need to connect to a Cluster management server in order to function. The exceptions are `ndb_size.pl` (see below), and the following utilities which access a cluster data node filesystem and so need to be run on a data node host:

- `ndb_print_backup_file`

- `ndb_print_schema_file`
- `ndb_print_sys_file`

`ndb_size.pl` is a Perl script which is also intended to be used from the shell; however it is a MySQL application and must be able to connect to a MySQL server. See [Section 15.9.13, “ndb_size.pl”](#), for additional requirements for using this script.

`ndb_error_reporter` is also a Perl script. It is used to gather cluster data node and management node logs together into a tarball to submit along with a bug report. It can use `ssh` or `scp` to access the node filesystems remotely.

Additional information about each of these utilities (except for `ndb_mgm` and `ndb_restore`) can be found in the sections that follow.

Note: All of these utilities (except for `ndb_size.pl` and `ndb_config`) can use the options discussed in [Section 15.6.5, “Command Options for MySQL Cluster Processes”](#). Additional options specific to each utility program are discussed in the individual program listings.

The order in which these options are used is generally not important. For example, all of these commands produce exactly the same output:

- `ndb_desc -c localhost fish -d test`
- `ndb_desc fish -c localhost -d test`
- `ndb_desc -d test fish -c localhost`

15.9.1. `ndb_config`

Description: This tool extracts configuration information for data nodes, SQL nodes, and API nodes from a cluster management node (and possibly its `config.ini` file).

Usage:

```
ndb_config options
```

The *options* available for this utility differ somewhat from those used with the other utilities, and so are listed in their entirety in the next section, followed by some examples.

Options:

- `--usage`, `--help`, or `-?`

Causes `ndb_config` to print a list of available options, and then exit.

- `--version`, `-V`

Causes `ndb_config` to print a version information string, and then exit.

- `--ndb-connectstring=connect_string`

Specifies the `connectstring` to use in connecting to the management server. The format for the connectstring is the same as described in [Section 15.4.4.2, “The Cluster connectstring”](#), and defaults to `localhost:1186`.

Note: The use of `-c` as a short version for this option is not currently supported with `ndb_config`.

- `--config-file=path-to-file`

Gives the path to the management server's configuration file (`config.ini`). This may be a relative or absolute path. If the management node resides on a different host from the one on which `ndb_config` is invoked, then an absolute path must be used.

- `--query=query-options, -q query-options`

This is a comma-delimited list of *query options* — that is, a list of one or more node attributes to be returned. These include `id` (node ID), `type` (node type — that is, `ndbd`, `mysqld`, or `ndb_mgmd`), and any configuration parameters whose values are to be obtained.

For example, `--query=id,type,indexmemory,datamemory` would return the node ID, node type, `DataMemory`, and `IndexMemory` for each node.

Note: If a given parameter is not applicable to a certain type of node, then an empty string is returned for the corresponding value. See the examples later in this section for more information.

- `--host=hostname`

Specifies the hostname of the node for which configuration information is to be obtained.

- `--id=node_id, --nodeid=node_id`

Used to specify the node ID of the node for which configuration information is to be obtained.

- `--nodes`

(Tells `ndb_config` to print information from parameters defined in `[ndbd]` sections only. Currently, using this option has no affect, since these are the only values checked, but it may become possible in future to query parameters set in `[tcp]` and other sections of cluster configuration files.)

- `--type=node_type`

Filters results so that only configuration values applying to nodes of the specified *node_type* (`ndbd`, `mysqld`, or `ndb_mgmd`) are returned.

- `--fields=delimiter, -f delimiter`

Specifies a *delimiter* string used to separate the fields in the result. The default is “,” (the comma character).

Note: If the *delimiter* contains spaces or escapes (such as `\n` for the linefeed character), then it must be quoted.

- `--rows=separator, -r separator`

Specifies a *separator* string used to separate the rows in the result. The default is a space character.

Note: If the *separator* contains spaces or escapes (such as `\n` for the linefeed character), then it must be quoted.

Examples:

1. To obtain the node ID and type of each node in the cluster:

```
shell> ./ndb_config --query=id,type --fields=':' --rows='\n'
1:ndbd
2:ndbd
3:ndbd
4:ndbd
5:ndb_mgmd
6:mysqlqld
7:mysqlqld
8:mysqlqld
9:mysqlqld
```

In this example, we used the `--fields` options to separate the ID and type of each node with a colon character (:), and the `--rows` options to place the values for each node on a new line in the output.

2. To produce a connectstring that can be used by data, SQL, and API nodes to connect to the management server:

```
shell> ./ndb_config --config-file=usr/local/mysql/cluster-data/config.ini --query=hostname,portnum
192.168.0.179:1186
```

3. This invocation of `ndb_config` checks only data nodes (using the `--type` option), and shows the values for each node's ID and hostname, and its `DataMemory`, `IndexMemory`, and `DataDir` parameters:

```
shell> ./ndb_config --type=ndbd --query=id,host,datamemory,indexmemory,datadir -f ' : ' -r '\n'
1 : 192.168.0.193 : 83886080 : 18874368 : /usr/local/mysql/cluster-data
2 : 192.168.0.112 : 83886080 : 18874368 : /usr/local/mysql/cluster-data
3 : 192.168.0.176 : 83886080 : 18874368 : /usr/local/mysql/cluster-data
4 : 192.168.0.119 : 83886080 : 18874368 : /usr/local/mysql/cluster-data
```

In this example, we used the short options `-f` and `-r` for setting the field delimiter and row separator, respectively.

4. To exclude results from any host except one in particular, use the `--host` option:

```
shell> ./ndb_config --host=192.168.0.176 -f : -r '\n' -q id,type
3:ndbd
5:ndb_mgmd
```

In this example, we also used the short form `-q` to determine the attributes to be queried.

Similarly, you can limit results to a node with a specific ID using the `--id` or `--nodeid` option.

15.9.2. `ndb_delete_all`

Description: Deletes all rows from the given NDB table. In some cases, this can be much faster than `DELETE` or even `TRUNCATE`.

Usage:

```
ndb_delete_all -c connect_string tbl_name -d db_name
```

This deletes all rows from the table named `tbl_name` in the database named `db_name`. It is exactly equivalent to executing `TRUNCATE db_name.tbl_name` in MySQL.

Additional Options:

- `-t, --transactional`

Use of this option causes the delete operation to be performed as a single transaction.

Warning: With very large tables, this using this option may cause the number of operations available to the cluster to be exceeded.

15.9.3. `ndb_desc`

Description: Provides a detailed description of one or more [NDB](#) tables.

Usage:

```
ndb_desc -c connect_string tbl_name -d db_name
```

Sample Output:

MySQL table creation and population statements:

```
USE test;

CREATE TABLE fish (
  id INT(11) NOT NULL AUTO_INCREMENT,
  name VARCHAR(20),

  PRIMARY KEY pk (id),
  UNIQUE KEY uk (name)
) ENGINE=NDBCLUSTER;

INSERT INTO fish VALUES
  ('','guppy'), ('','tuna'), ('','shark'),
  ('','manta ray'), ('','grouper'), ('','puffer');
```

Output from `ndb_desc`:

```
shell> ./ndb_desc -c localhost fish -d test -p
-- fish --
Version: 16777221
Fragment type: 5
K Value: 6
Min load factor: 78
Max load factor: 80
Temporary table: no
Number of attributes: 2
Number of primary keys: 1
Length of frm data: 268
Row Checksum: 1
Row GCI: 1
TableStatus: Retrieved
-- Attributes --
id Int PRIMARY KEY DISTRIBUTION KEY AT=FIXED ST=MEMORY
name Varchar(20;latin1_swedish_ci) NULL AT=SHORT_VAR ST=MEMORY

-- Indexes --
PRIMARY KEY(id) - UniqueHashIndex
uk(name) - OrderedIndex
PRIMARY(id) - OrderedIndex
uk$unique(name) - UniqueHashIndex

-- Per partition info --
Partition  Row count  Commit count  Frag fixed memory  Frag varsized memory
2          2           2             65536              327680
1          2           2             65536              327680
3          2           2             65536              327680

NDBT_ProgramExit: 0 - OK
```

Additional Options:

- `-p, --extra-partition-info`
Prints additional information about the table's partitions.
- Information about multiple tables can be obtained in a single invocation of `ndb_desc` by using their names, separated by spaces. All of the tables must be in the same database.

15.9.4. `ndb_drop_index`

Description: Drops the specified index from an NDB table. *It is recommended that you use this utility only as an example for writing NDB API applications* — see the Warning later in this section for details.

Usage:

```
ndb_drop_index -c connect_string table_name index -d db_name
```

The statement shown above drops the index named `index` from the `table` in the `database`.

Additional Options: None that are specific to this application.

Warning: *Operations performed on Cluster table indexes using the NDB API are not visible to MySQL and make the table unusable by a MySQL server.* If you use this program to drop an index, then try to access the table from an SQL node, an error results, as shown here:

```
shell> ./ndb_drop_index -c localhost dogs ix -d ctest1
Dropping index dogs/idx...OK

NDBT_ProgramExit: 0 - OK

shell> ./mysql -u jon -p ctest1
Enter password: *****
Reading table information for completion of table and column names
You can turn off this feature to get a quicker startup with -A

Welcome to the MySQL monitor.  Commands end with ; or \g.
Your MySQL connection id is 7 to server version: 5.1.12-beta-20060817

Type 'help;' or '\h' for help. Type '\c' to clear the buffer.

mysql> SHOW TABLES;
+-----+
| Tables_in_ctest1 |
+-----+
| a                 |
| bt1               |
| bt2               |
| dogs              |
| employees         |
| fish              |
+-----+
6 rows in set (0.00 sec)

mysql> SELECT * FROM dogs;
ERROR 1296 (HY000): Got error 4243 'Index not found' from NDBCLUSTER
```

In such a case, your *only* option for making the table available to MySQL again is to drop the table and re-create it. You can use either the SQL statement `DROP TABLE` or the `ndb_drop_table` utility (see [Section 15.9.5, “ndb_drop_table”](#)) to drop the table.

15.9.5. `ndb_drop_table`

Description: Drops the specified NDB table. (If you try to use this on a table created with a storage engine other than NDB, it fails with the error 723: No such table exists.) This operation is extremely fast — in some cases, it can be an order of magnitude faster than using `DROP TABLE` on an NDB table from

MySQL.

Usage:

```
ndb_drop_table -c connect_string tbl_name -d db_name
```

Additional Options: None.

15.9.6. `ndb_error_reporter`

Description: Creates an archive from data node and management node logfiles that can be used to help diagnose bugs or other problems with a cluster. *It is highly recommended that you make use of this utility when filing reports of bugs in MySQL Cluster.*

Usage:

```
ndb_error_reporter path/to/config-file [username] [--fs]
```

This utility is intended for use on a management node host, and requires the path to the management host configuration file (`config.ini`). Optionally, you can supply the name of a user that is able to access the cluster's data nodes via SSH, in order to copy the data node logfiles. `ndb_error_reporter` then includes all of these files in archive that is created in the same directory in which it is run. The archive is named `ndb_error_report_YYYYMMDDHHMMSS.tar.bz2`, where `YYYYMMDDHHMMSS` is a date-time string.

If the `--fs` is used, then the data node filesystems are also copied to the management host and included in the archive that is produced by this script. As data node filesystems can be extremely large even after being compressed, we ask that you please do *not* send archives created using this option to MySQL AB unless you are specifically requested to do so.

15.9.7. `ndb_print_backup_file`

Description: Obtains diagnostic information from a cluster backup file.

Usage:

```
ndb_print_backup_file file_name
```

`file_name` is the name of a cluster backup file. This can be any of the files (`.Data`, `.ctl`, or `.log` file) found in a cluster backup directory. These files are found in the data node's backup directory under the subdirectory `BACKUP-#`, where `#` is the sequence number for the backup. For more information about cluster backup files and their contents, see [Section 15.8.1, “Cluster Backup Concepts”](#).

Like `ndb_print_schema_file` and `ndb_print_sys_file` (and unlike most of the other `NDB` utilities that are intended to be run on a management server host or to connect to a management server) `ndb_print_backup_file` must be run on a cluster data node, since it accesses the data node filesystem directly. Because it does not make use of the management server, this utility can be used when the management server is not running, and even when the cluster has been completely shut down.

Additional Options: None.

15.9.8. `ndb_print_schema_file`

Description: Obtains diagnostic information from a cluster schema file.

Usage:

```
ndb_print_schema_file file_name
```

file_name is the name of a cluster schema file.

Like `ndb_print_backup_file` and `ndb_print_sys_file` (and unlike most of the other NDB utilities that are intended to be run on a management server host or to connect to a management server) `ndb_print_backup_file` must be run on a cluster data node, since it accesses the data node filesystem directly. Because it does not make use of the management server, this utility can be used when the management server is not running, and even when the cluster has been completely shut down.

Additional Options: None.

15.9.9. `ndb_print_sys_file`

Description: Obtains diagnostic information from a cluster system file.

Usage:

```
ndb_print_sys_file file_name
```

file_name is the name of a cluster system file (sysfile). Cluster system files are located in a data node's data directory (`DataDir`); the path under this directory to system files matches the pattern `ndb_#_fs/D#/DBDIH/P#.sysfile`. In each case, the `#` represents a number (not necessarily the same number).

Like `ndb_print_backup_file` and `ndb_print_schema_file` (and unlike most of the other NDB utilities that are intended to be run on a management server host or to connect to a management server) `ndb_print_backup_file` must be run on a cluster data node, since it accesses the data node filesystem directly. Because it does not make use of the management server, this utility can be used when the management server is not running, and even when the cluster has been completely shut down.

Additional Options: None.

15.9.10. `ndb_select_all`

Description: Prints all rows from an NDB table to `stdout`.

Usage:

```
ndb_select_all -c connect_string tbl_name -d db_name [> file_name]
```

Additional Options:

- `-l lock_type, --lock=lock_type`

Employs a lock when reading the table. Possible values for *lock_type* are:

- 0: Read lock
- 1: Read lock with hold
- 2: Exclusive read lock

There is no default value for this option.

- `-o index_name, --order=index_name`

Orders the output according to the index named *index_name*. Note that this is the name of an index, not of a column, and that the index must have been explicitly named when created.

- `-z, --descending`

Sorts the output in descending order. This option can be used only in conjunction with the `-o` (`-order`) option.

- `--header=FALSE`

Excludes column headers from the output.

- `-x, --useHexFormat`

Causes all numeric values to be displayed in hexadecimal format. This does not affect the output of numerals contained in strings or datetime values.

`-D character, --delimiter=character`

Causes the *character* to be used as a column delimiter. Only table data columns are separated by this delimiter.

The default delimiter is the tab character.

- `--disk`

Adds a disk reference column to the output. The column is non-empty only for Disk Data tables having non-indexed columns.

- `--rowid`

Adds a `ROWID` column providing information about the fragments in which rows are stored.

- `--gci`

Adds a column to the output showing the global checkpoint at which each row was last updated. See [Section 15.16, “MySQL Cluster Glossary”](#), and [Section 15.7.3.2, “Log Events”](#), for more information about checkpoints.

- `-t, --tupscan`

Scan the table in the order of the tuples.

- `--nodata`

Causes any table data to be omitted.

Sample Output:

Output from a MySQL `SELECT` statement:

```
mysql> SELECT * FROM ctest1.fish;
+-----+
| id | name |
+-----+
| 3 | shark |
| 6 | puffer |
| 2 | tuna |
| 4 | manta ray |
| 5 | grouper |
| 1 | guppy |
+-----+
```

```
+-----+
6 rows in set (0.04 sec)
```

Output from the equivalent invocation of `ndb_select_all`:

```
shell> ./ndb_select_all -c localhost fish -d ctest1
id      name
3       [shark]
6       [puffer]
2       [tuna]
4       [manta ray]
5       [grouper]
1       [guppy]
6 rows returned

NDBT_ProgramExit: 0 - OK
```

Note that all string values are enclosed by square brackets (“[...]”) in the output of `ndb_select_all`. For a further example, consider the table created and populated as shown here:

```
CREATE TABLE dogs (
  id INT(11) NOT NULL AUTO_INCREMENT,
  name VARCHAR(25) NOT NULL,
  breed VARCHAR(50) NOT NULL,
  PRIMARY KEY pk (id),
  KEY ix (name)
)
TABLESPACE ts STORAGE DISK
ENGINE=NDB;

INSERT INTO dogs VALUES
  ('', 'Lassie', 'collie'),
  ('', 'Scooby-Doo', 'Great Dane'),
  ('', 'Rin-Tin-Tin', 'Alsation'),
  ('', 'Rosscoe', 'Mutt');
```

This demonstrates the use of several additional `ndb_select_all` options:

```
shell> ./ndb_select_all -d ctest1 dogs -o ix -z --gci --disk
GCI      id name      breed      DISK_REF
834461   2 [Scooby-Doo] [Great Dane] [ m_file_no: 0 m_page: 98 m_page_idx: 0 ]
834878   4 [Rosscoe]    [Mutt]      [ m_file_no: 0 m_page: 98 m_page_idx: 16 ]
834463   3 [Rin-Tin-Tin] [Alsation]  [ m_file_no: 0 m_page: 34 m_page_idx: 0 ]
835657   1 [Lassie]     [Collie]   [ m_file_no: 0 m_page: 66 m_page_idx: 0 ]
4 rows returned

NDBT_ProgramExit: 0 - OK
```

15.9.11. `ndb_select_count`

Description: Prints the number of rows in one or more NDB table. With a single table, the result is equivalent to that obtained by using the MySQL statement `SELECT COUNT(*) FROM tbl_name`.

Usage:

```
ndb_select_count [-c connect_string] -ddb_name tbl_name[, tbl_name2[, ...]]
```

Additional Options: None that are specific to this application. However, you can obtain row counts from multiple tables in the same database by listing the table names separated by spaces when invoking this command, as shown under **Sample Output**.

Sample Output:

```
shell> ./ndb_select_count -c localhost -d ctest1 fish dogs
6 records in table fish
4 records in table dogs
```

```
NDBT_ProgramExit: 0 - OK
```

15.9.12. `ndb_show_tables`

Description: Displays a list of all [NDB](#) database objects in the cluster. By default, this includes not only both user-created tables and [NDB](#) system tables, but [NDB](#)-specific indexes, internal triggers, and Cluster Disk Data objects as well.

Usage:

```
ndb_show_tables [-c connect_string]
```

Additional Options:

- `-l, --loops`

Specifies the number of times the utility should execute. This is 1 when this option is not specified, but if you do use the option, you must supply an integer argument for it.

- `-p, --parsable`

Using this option causes the output to be in a format suitable for use with `LOAD DATA INFILE`.

- `-t, --type`

Can be used to restrict the output to one type of object, specified by an integer type code as shown here:

- **1:** System table
- **2:** User-created table
- **3:** Unique hash index

Any other value causes all [NDB](#) database objects to be listed (the default).

- `-u, --unqualified`

If specified, this causes unqualified object names to be displayed.

Note: Only user-created Cluster tables may be accessed from MySQL; system tables such as `SYSTAB_0` are not visible to `mysqld`. However, you can examine the contents of system tables using [NDB](#) API applications such as `ndb_select_all` (see [Section 15.9.10](#), “`ndb_select_all`”).

15.9.13. `ndb_size.pl`

Description: This is a Perl script that can be used to estimate the amount of space that would be required by a MySQL database if it were converted to use the [NDBCluster](#) storage engine. Unlike the other utilities discussed in this section, it does not require access to a MySQL Cluster (in fact, there is no reason for it to do so). However, it does need to access the MySQL server on which the database to be tested resides.

Requirements:

- A running MySQL server. The server instance does not have to provide support for MySQL Cluster.

- A working installation of Perl.
- The `DBI` and `HTML::Template` modules, both of which can be obtained from CPAN if they are not already part of your Perl installation. (Many Linux and other operating system distributions provide their own packages for one or both of these libraries.)
- The `ndb_size.tpl` template file, which you should be able to find in the `share/mysql` directory of your MySQL installation. This file should be copied or moved into the same directory as `ndb_size.pl` — if it is not there already — before running the script.
- A MySQL user account having the necessary privileges. If you do not wish to use an existing account, then creating one using `GRANT USAGE ON db_name.*` — where `db_name` is the name of the database to be examined — is sufficient for this purpose.

`ndb_size.pl` and `ndb_size.tpl` can also be found in the MySQL sources in `storage/ndb/tools`. If these files are not present in your MySQL installation, you can obtain them from the [MySQLForge project page](http://forge.mysql.com/projects/view.php?id=88) [http://forge.mysql.com/projects/view.php?id=88].

Usage:

```
perl ndb_size.pl db_name hostname username password > file_name.html
```

The command shown connects to the MySQL server at `hostname` using the account of the user `username` having the password `password`, analyses all of the tables in database `db_name`, and generates a report in HTML format which is directed to the file `file_name.html`. (Without the redirection, the output is sent to `stdout`.) This figure shows partial sample output as viewed in a Web browser:

MySQL Cluster analysis for world

This is an automated analysis of the DBI:mysql:database=world;host=192.168.0.176 database for migration into MySQL Cluster. No warranty is made to the accuracy of the information.

This information should be valid for MySQL 4.1 and 5.0. Since 5.1 is not a final release yet, the numbers should be used as a guide only.

Parameter Settings

NOTE the configuration parameters below do not take into account system tables and other requirements.

Parameter	4.1	5.0	5.1
DataMemory (kb)	544	544	544
IndexMemory (kb)	192	136	136
MaxNoOfTables	3	3	3
MaxNoOfAttributes	24	24	24
MaxNoOfOrderedIndexes	3	3	3
MaxNoOfUniqueHashIndexes	3	3	3
MaxNoOfTriggers	12	12	12

Memory usage because of parameters

Usage is in kilobytes. Actual usage will vary as you should set the parameters larger than those listed in the table above.

Parameter	4.1	5.0	5.1
Attributes	5	5	5
Tables	60	60	60
OrderedIndexes	30	30	30
UniqueHashIndexes	45	45	45

Table List

- [City](#)
- [Country](#)
- [CountryLanguage](#)

City

Column	Type	Size	Key	4.1 NDB Size	5.0 NDB Size	5.1 NDB Size
ID	int	11	PR1	4	4	4
District	char	20		20	20	20
Name	char	35		36	36	36
Population	int	11		4	4	4
CountryCode	char	3		4	4	4

Indexes

We assume that indexes are ORDERED (not created USING HASH). If order is not required, 10 bytes of data memory can be saved per row if the index is created USING HASH

Index	Type	Columns	4.1 IdxMem	5.0 IdxMem	5.1 IdxMem	4.1 DatMem	5.0 DatMem	5.1 DatMem
PRIMARY	BTREE	ID	29	25	25	10	10	10

DataMemory Usage

	4.1	5.0	5.1
Row Overhead	16	16	16
Column DataMemory/Row	68	68	68
Index DataMemory/Row	10	10	10
Total DataMemory/Row	94	94	94
Rows per 32 kb page	347	347	347
Current number of rows	4079	4079	4079
Total DataMemory (kb)	384	384	384

IndexMemory Usage

	4.1	5.0	5.1
IndexMemory/Row	29	25	25
Rows per 8kb page	282	327	327
Current number of rows	4079	4079	4079
Total IndexMemory (kb)	120	104	104

The output from this script includes:

- Minimum values for the `DataMemory`, `IndexMemory`, `MaxNoOfTables`, `MaxNoOfAttributes`, `MaxNoOfOrderedIndexes`, `MaxNoOfUniqueHashIndexes`, and `MaxNoOfTriggers` configuration parameters required to accommodate the tables analysed.
- Memory requirements for all of the tables, attributes, ordered indexes, and unique hash indexes defined in the database.
- The `IndexMemory` and `DataMemory` required per table and table row.

15.9.14. `ndb_waiter`

Description: Repeatedly (each 100 milliseconds) prints out the status of all cluster data nodes until either the cluster reaches a given status or the `--timeout` limit is exceeded, then exits. By default, it waits for the cluster to achieve `STARTED` status, in which all nodes have started and connected to the cluster. This can be overridden using the `--no-contact` and `--not-started` options (see [Additional Options](#)).

The node states reported by this utility are as follows:

- `NO_CONTACT`: The node cannot be contacted.
- `UNKNOWN`: The node can be contacted, but its status is not yet known. Usually, this means that the node has received a `START` or `RESTART` command from the management server, but has not yet acted on it.
- `NOT_STARTED`: The node has stopped, but remains in contact with the cluster. This is seen when restarting the node using the management client's `RESTART` command.
- `STARTING`: The node's `ndbd` process has started, but the node has not yet joined the cluster.
- `STARTED`: The node is operational, and has joined the cluster.
- `SHUTTING_DOWN`: The node is shutting down.
- `SINGLE USER MODE`: This is shown for all cluster data nodes when the cluster is in single user mode.

Usage:

```
ndb_waiter [-c connect_string]
```

Additional Options:

- `-n, --no-contact`

Instead of waiting for the `STARTED` state, `ndb_waiter` continues running until the cluster reaches `NO_CONTACT` status before exiting.

- `--not-started`

Instead of waiting for the `STARTED` state, `ndb_waiter` continues running until the cluster reaches `NOT_STARTED` status before exiting.

- `-t, --timeout=#`

Time to wait. The program exits if the desired state is not achieved within this number of seconds. The default is 120 seconds (1200 reporting cycles).

Sample Output:

Shown here is the output from `ndb_waiter` when run against a 4-node cluster in which two nodes have been shut down and then started again manually. Duplicate reports (indicated by “...”) are omitted.

```
shell> ./ndb_waiter -c localhost

Connecting to mgmsrv at (localhost)
State node 1 STARTED
State node 2 NO_CONTACT
State node 3 STARTED
State node 4 NO_CONTACT
Waiting for cluster enter state STARTED

...

State node 1 STARTED
State node 2 UNKNOWN
State node 3 STARTED
State node 4 NO_CONTACT
Waiting for cluster enter state STARTED

...

State node 1 STARTED
State node 2 STARTING
State node 3 STARTED
State node 4 NO_CONTACT
Waiting for cluster enter state STARTED

...

State node 1 STARTED
State node 2 STARTING
State node 3 STARTED
State node 4 UNKNOWN
Waiting for cluster enter state STARTED

...

State node 1 STARTED
State node 2 STARTING
State node 3 STARTED
State node 4 STARTING
Waiting for cluster enter state STARTED

...

State node 1 STARTED
State node 2 STARTED
State node 3 STARTED
State node 4 STARTING
Waiting for cluster enter state STARTED

...

State node 1 STARTED
State node 2 STARTED
State node 3 STARTED
State node 4 STARTED
Waiting for cluster enter state STARTED

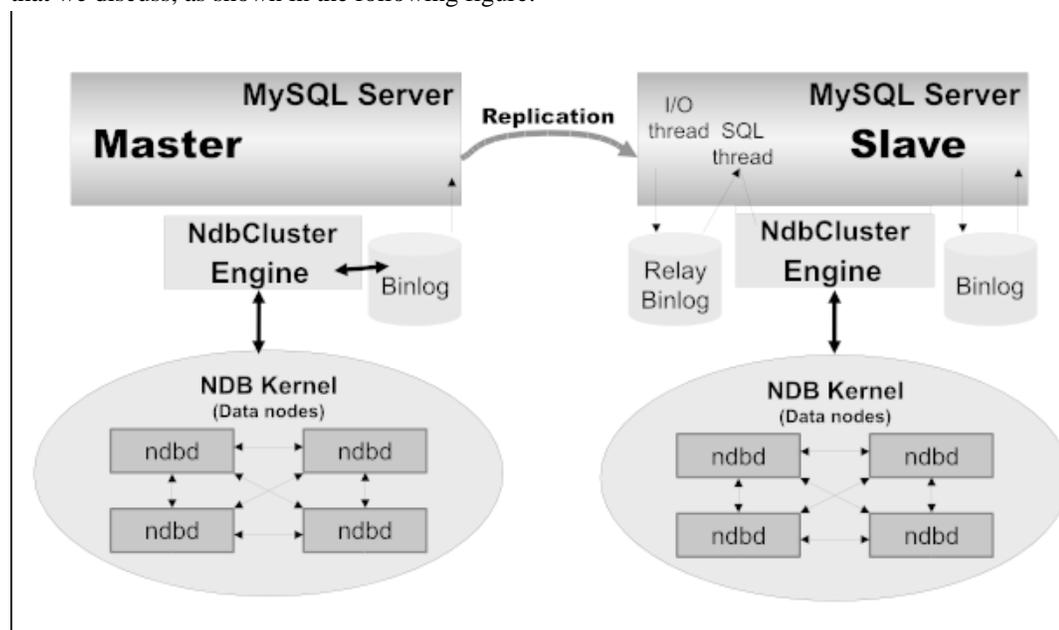

NDBT_ProgramExit: 0 - OK
```

Note: If no connectstring is specified, then `ndb_waiter` tries to connect to a management on `localhost`, and reports `Connecting to mgmsrv at (null)`.

15.10. MySQL Cluster Replication

Previous to MySQL 5.1.6, *asynchronous replication*, more usually referred to simply as “replication”, was not available when using MySQL Cluster. MySQL 5.1.6 introduces master-slave replication of this type for MySQL Cluster databases. This section explains how to set up and manage a configuration wherein one group of computers operating as a MySQL Cluster replicates to a second computer or group of computers. We assume some familiarity on the part of the reader with standard MySQL replication as discussed elsewhere in this Manual. (See [Chapter 6, Replication](#)).

Normal (non-clustered) replication involves a “master” server and a “slave” server, the master being the source of the operations and data to be replicated and the slave being the recipient of these. In MySQL Cluster, replication is conceptually very similar but can be more complex in practice, as it may be extended to cover a number of different configurations including replicating between two complete clusters. Although a MySQL Cluster itself depends on the [NDB Cluster](#) storage engine for clustering functionality, it is not necessary to use the Cluster storage engine on the slave. However, for maximum availability, it is possible to replicate from one MySQL Cluster to another, and it is this type of configuration that we discuss, as shown in the following figure:

In this scenario, the replication process is one in which successive states of a master cluster are logged and saved to a slave cluster. This process is accomplished by a special thread known as the NDB binlog injector thread, which runs on each MySQL server and produces a binary log ([binlog](#)). This thread ensures that all changes in the cluster producing the binary log — and not just those changes that are effected via the MySQL Server — are inserted into the binary log with the correct serialization order. We refer to the MySQL replication master and replication slave servers as replication servers or replication nodes, and the data flow or line of communication between them as a *replication channel*.

15.10.1. Abbreviations and Symbols

Throughout this section, we use the following abbreviations or symbols for referring to the master and slave clusters, and to processes and commands run on the clusters or cluster nodes:

Symbol or Abbreviation	Description (Refers to...)
<i>M</i>	The cluster serving as the (primary) replication master
<i>S</i>	The cluster acting as the (primary) replication slave

<code>shellM></code>	Shell command to be issued on the master cluster
<code>mysqlM></code>	MySQL client command issued on a single MySQL server running as an SQL node on the master cluster
<code>mysqlM*></code>	MySQL client command to be issued on all SQL nodes participating in the replication master cluster
<code>shellS></code>	Shell command to be issued on the slave cluster
<code>mysqlS></code>	MySQL client command issued on a single MySQL server running as an SQL node on the slave cluster
<code>mysqlS*></code>	MySQL client command to be issued on all SQL nodes participating in the replication slave cluster
<code>C</code>	Primary replication channel
<code>C'</code>	Secondary replication channel
<code>M'</code>	Secondary replication master
<code>S'</code>	Secondary replication slave

15.10.2. Assumptions and General Requirements

A replication channel requires two MySQL servers acting as replication servers (one each for the master and slave). For example, this means that in the case of a replication setup with two replication channels (to provide an extra channel for redundancy), there will be a total of four replication nodes, two per cluster.

Replication of a MySQL Cluster as described in this section and those following is dependent on row-based replication. This means that the replication master MySQL server must be started with `--binlog-format=row`, as described in [Section 15.10.6, “Starting Replication \(Single Replication Channel\)”](#). For general information about row-based replication, see [Section 6.3, “Row-Based Replication”](#).

(It is possible to replicate a MySQL Cluster using statement-based replication. However, in this case, the following restrictions apply: All updates to data rows on the cluster acting as the master must be directed to a single MySQL server; It is not possible to replicate a cluster using several MySQL replication processes at the same time; Only changes made at the SQL level are replicated.)

Each MySQL server used for replication in either cluster must be uniquely identified among all the MySQL replication servers participating in either cluster (you cannot have replication servers on both the master and slave clusters sharing the same ID). This can be done by starting each SQL node using the `--server-id=id` option, where `id` is a unique integer. Although it is not strictly necessary, we will assume for purposes of this discussion that all MySQL installations are the same version.

In any event, both MySQL servers involved in replication must be compatible with one another with respect to both the version of the replication protocol used and the SQL feature sets which they support; the simplest and easiest way to assure that this is the case is to use the same MySQL version for all servers involved. Note that in many cases it is not possible to replicate to a slave running a version of MySQL with a lower version number than that of the master — see [Section 6.6, “Replication Compatibility Between MySQL Versions”](#), for details.

We assume that the slave server or cluster is dedicated to replication of the master, and that no other data is being stored on it.

15.10.3. Known Issues

The following are known problems or issues when using replication with MySQL Cluster in MySQL

5.1:

- A MySQL Cluster replication slave `mysqld` has no way of detecting that the connection from the master has been interrupted, and no buffering of the log takes place. For this reason, if a problem such as the master going down or a network failure occurring, then it is possible for the slave to become inconsistent with the master.

To guard against this possibility, it is advisable to set up multiple replication lines, to monitor the master `mysqld` on the primary replication line, and to fail over to a secondary line if and as necessary.

For information about implementing this type of setup, see [Section 15.10.7, “Using Two Replication Channels”](#), and [Section 15.10.8, “Implementing Failover with MySQL Cluster”](#).

We are working on an integrated solution to this problem for inclusion in a future MySQL Cluster release. (See the discussion of this issue in [Bug#21494](http://bugs.mysql.com/21494) [<http://bugs.mysql.com/21494>].)

- Circular replication is not supported for Cluster replication. This is because all log events created in a particular MySQL Cluster are wrongly tagged with the server id of the MySQL server used as master and not with the server id of the originating server.

Because of this misidentification, replicating between MySQL servers $A \rightarrow B \rightarrow A$, where B is any MySQL server connected to a cluster A , causes the cluster table changes (log entries) of A to “lose” the originating server’s identifier in the log from B to A . This causes the changes to be reapplied on server A .

- The use of data definition statements, such as `CREATE TABLE`, `DROP TABLE`, and `ALTER TABLE`, are recorded in the binary log for only the MySQL server on which they are issued.
- In MySQL 5.1.6, only those `NDB` tables having explicit primary keys could be replicated. This limitation was lifted in MySQL 5.1.7.
- A MySQL server involved in replication should be started or restarted after using `ndb_restore` to discover and setup replication of `NDB Cluster` tables. Alternatively, you can issue a `SHOW TABLES` statement on all databases in the cluster.

Similarly, when using `CREATE SCHEMA`, the new database is not automatically discoverable by the MySQL server. Thus, this statement must be issued on each MySQL server participating in the cluster when creating a new database.

- Restarting the cluster with the `--initial` option will cause the sequence of GCI and epoch numbers to start over from 0. (This is generally true of MySQL Cluster and not limited to replication scenarios involving Cluster.) The MySQL servers involved in replication should in this case be replicated. After this, you should use the `RESET MASTER` and `RESET SLAVE` statements to clear the invalid `binlog_index` and `apply_status` tables, respectively.
- Trying to set values for the `auto_increment_offset` and `auto_increment_increment` server system variables produces unpredictable results. The use of these variables is not supported with MySQL Cluster replication.

See [Section 15.10.9.2, “Initiating Discovery of Schema Changes”](#), for more information about the first two items listed above, as well as some examples illustrating how to handle applicable situations.

15.10.4. Replication Schema and Tables

Replication in MySQL Cluster makes use of a number of dedicated tables in a separate `cluster` data-

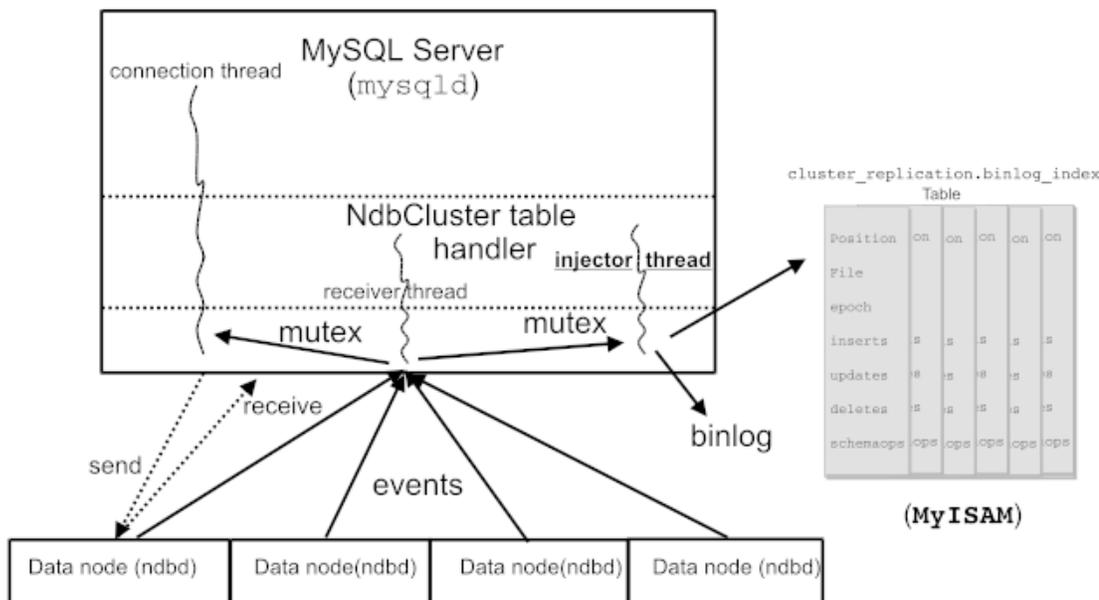

base on each MySQL Server instance acting as an SQL node in both the cluster being replicated and the replication slave (whether the slave is a single server or a cluster). This database, which is created during the MySQL installation process by the `mysql_install_db` script, contains a table for storing the binary log's indexing data. As the `binlog_index` table is local to each MySQL server and does not participate in clustering, it uses the `MyISAM` storage engine, and so must be created separately on each `mysqld` participating in the master cluster. (However, the binlog itself contains updates from all MySQL servers in the cluster to be replicated.) This table is defined as follows:

```
CREATE TABLE `binlog_index` (
  `Position` BIGINT(20) UNSIGNED NOT NULL,
  `File` VARCHAR(255) NOT NULL,
  `epoch` BIGINT(20) UNSIGNED NOT NULL,
  `inserts` BIGINT(20) UNSIGNED NOT NULL,
  `updates` BIGINT(20) UNSIGNED NOT NULL,
  `deletes` BIGINT(20) UNSIGNED NOT NULL,
  `schemaops` BIGINT(20) UNSIGNED NOT NULL,
  PRIMARY KEY (`epoch`)
) ENGINE=MYISAM DEFAULT CHARSET=latin1;
```

Important: Prior to MySQL 5.1.8, the `cluster` database was known as the `cluster_replication` database.

The following figure shows the relationship of the MySQL Cluster replication master server, its binlog injector thread, and the `cluster.binlog_index` table.

MySQL Replication Between Clusters, Injecting into Binlog

An additional table, named `apply_status`, is used to keep a record of the operations that have been replicated from the master to the slave. Unlike the case with `binlog_index`, the data in this table is not specific to any one SQL node in the (slave) cluster, and so `apply_status` can use the `NDB Cluster` storage engine, as shown here:

```
CREATE TABLE `apply_status` (
  `server_id` INT(10) UNSIGNED NOT NULL,
```

```
`epoch` BIGINT(20) UNSIGNED NOT NULL,
PRIMARY KEY USING HASH (`server_id`)
) ENGINE=NDBCLUSTER DEFAULT CHARSET=latin1;
```

The `binlog_index` and `apply_status` tables are created in a separate database because they should not be replicated. No user intervention is normally required to create or maintain either of them. Both the `binlog_index` and the `apply_status` tables are maintained by the NDB injector thread. This keeps the master `mysqld` process updated to changes performed by the NDB storage engine. The NDB *binlog injector thread* receives events directly from the NDB storage engine. The NDB injector is responsible for capturing all the data events within the cluster, and ensures that all events changing, inserting, or deleting data are recorded in the `binlog_index` table. The slave I/O thread will transfer the events from the master's binary log to the slave's relay log.

However, it is advisable to check for the existence and integrity of these tables as an initial step in preparing a MySQL Cluster for replication. It is possible to view event data recorded in the binary log by querying the `cluster.binlog_index` table directly on the master. This can be also be accomplished using the `SHOW BINLOG EVENTS` statement on either the replication master or slave MySQL servers.

15.10.5. Preparing the Cluster for Replication

Preparing the MySQL Cluster for replication consists of the following steps:

1. Check all MySQL servers for version compatibility (see [Section 15.10.2, “Assumptions and General Requirements”](#)).
2. Create a slave account on the master Cluster with the appropriate privileges:

```
mysqlM> GRANT REPLICATION SLAVE
-> ON *.* TO 'slave_user'@'slave_host'
-> IDENTIFIED BY 'slave_password';
```

where `slave_user` is the slave account username, `slave_host` is the hostname or IP address of the replication slave, and `slave_password` is the password to assign to this account.

For example, to create a slave user account with the name “`myslave`,” logging in from the host named “`rep-slave`,” and using the password “`53cr37`,” use the following `GRANT` statement:

```
mysqlM> GRANT REPLICATION SLAVE
-> ON *.* TO 'myslave'@'rep-slave'
-> IDENTIFIED BY '53cr37';
```

For security reasons, it is preferable to use a unique user account — not employed for any other purpose — for the replication slave account.

3. Configure the slave to use the master. Using the MySQL Monitor, this can be accomplished with the `CHANGE MASTER TO` statement:

```
mysqlS> CHANGE MASTER TO
-> MASTER_HOST='master_host',
-> MASTER_PORT=master_port,
-> MASTER_USER='slave_user',
-> MASTER_PASSWORD='slave_password';
```

where `master_host` is the hostname or IP address of the replication master, `master_port` is the port for the slave to use for connecting to the master, `slave_user` is the username set up for the slave on the master, and `slave_password` is the password set for that user account in the previous step.

For example, to tell the slave to replicate from the MySQL server whose hostname is “`rep-master`,” using the replication slave account created in the previous step, use the following statement:

```
mysqlS> CHANGE MASTER TO
-> MASTER_HOST='rep-master'
-> MASTER_PORT=3306,
-> MASTER_USER='myslave'
-> MASTER_PASSWORD='53cr37';
```

(For a complete list of clauses that can be used with this statement, see [Section 13.6.2.1, “CHANGE MASTER TO Syntax”](#).)

You can also configure the slave to use the master by setting the corresponding startup options in the slave server's `my.cnf` file. To configure the slave in the same way as the preceding example `CHANGE MASTER TO` statement, the following information would need to be included in the slave's `my.cnf` file:

```
[mysqld]
master-host=rep-master
master-port=3306
master-user=myslave
master-password=53cr37
```

See [Section 6.9, “Replication Startup Options”](#), for additional options that can be set in `my.cnf` for replication slaves.

Note: To provide replication backup capability, you will also need to add an `ndb-connectstring` option to the slave's `my.cnf` file prior to starting the replication process. See [Section 15.10.9, “MySQL Cluster Backups With Replication”](#), for details.

4. If the master cluster is already in use, you can create a backup of the master and load this onto the slave to cut down on the amount of time required for the slave to synchronize itself with the master. If the slave is also running MySQL Cluster, this can be accomplished using the backup and restore procedure described in [Section 15.10.9, “MySQL Cluster Backups With Replication”](#).

```
ndb-connectstring=management_host[:port]
```

In the event that you are *not* using MySQL Cluster on the replication slave, you can create a backup with this command on the replication master:

```
shellM> mysqldump --master-data=1
```

Then import the resulting data dump onto the slave by copying the dump file over to the slave. After this, you can use the `mysql` client to import the data from the dumpfile into the slave database as shown here, where `dump_file` is the name of the file that was generated using `mysqldump` on the master, and `db_name` is the name of the database to be replicated:

```
shellS> mysql -u root -p db_name < dump_file
```

For a complete list of options to use with `mysqldump`, see [Section 8.11, “mysqldump — A Database Backup Program”](#).

Note that if you copy the data to the slave in this fashion, you should make sure that the slave is started with the `--skip-slave-start` option on the command line, or else include `skip-slave-start` in the slave's `my.cnf` file to keep it from trying to connect to the master to begin replicating before all the data has been loaded. Once the data loading has completed, follow the additional steps outlined in the next two sections.

5. Ensure that each MySQL server acting as a replication master is configured with a unique server ID, and with binary logging enabled, using the row format. (See [Section 6.3, “Row-Based Replication”](#).) These options can be set either in the master server's `my.cnf` file, or on the command line when starting the master `mysqld` process. See [Section 15.10.6, “Starting Replication \(Single Replication Channel\)”](#), for information regarding the latter option.

15.10.6. Starting Replication (Single Replication Channel)

This section outlines the procedure for starting MySQL Cluster replication using a single replication channel.

1. Start the MySQL replication master server by issuing this command:

```
shellM> mysqld --nbdcluster --server-id=id \  
--log-bin --binlog-format=row &
```

where `id` is this server's unique ID (see [Section 15.10.2, “Assumptions and General Requirements”](#)). This starts the server's `mysqld` process with binary logging enabled using the proper logging format.

2. Start the MySQL replication slave server as shown here:

```
shellS> mysqld --ndbcluster --server-id=id &
```

where `id` is the slave server's unique ID. It is not necessary to enable logging on the replication slave.

Note that you should use the `--skip-slave-start` option with this command or else you should include `skip-slave-start` in the slave server's `my.cnf` file, unless you want replication to begin immediately. With the use of this option, the start of replication is delayed until the appropriate `START SLAVE` statement has been issued, as explained in Step 4 below.

3. It is necessary to synchronize the slave server with the master server's replication binlog. If binary logging has not previously been running on the master, run the following statement on the slave:

```
mysqlS> CHANGE MASTER TO  
-> MASTER_LOG_FILE='',  
-> MASTER_LOG_POS=4;
```

This instructs the slave to begin reading the master's binary log from the log's starting point. Otherwise — that is, if you are loading data from the master using a backup — see [Section 15.10.8, “Implementing Failover with MySQL Cluster”](#), for information on how to obtain the correct values to use for `MASTER_LOG_FILE` and `MASTER_LOG_POS` in such cases.

4. Finally, you must instruct the slave to begin applying replication by issuing this command from the `mysql` client on the replication slave:

```
mysqlS> START SLAVE;
```

This also initiates the transmission of replication data from the master to the slave.

It is also possible to use two replication channels, in a manner similar to the procedure described in the next section; the differences between this and using a single replication channel are covered in [Section 15.10.7, “Using Two Replication Channels”](#).

15.10.7. Using Two Replication Channels

In a more complete example scenario, we envision two replication channels to provide redundancy and thereby guard against possible failure of a single replication channel. This requires a total of four replication servers, two masters for the master cluster and two slave servers for the slave cluster. For purposes of the discussion that follows, we assume that unique identifiers are assigned as shown here:

Server ID	Description
1	Master - primary replication channel (<i>M</i>)
2	Master - secondary replication channel (<i>M'</i>)
3	Slave - primary replication channel (<i>S</i>)
4	Slave - secondary replication channel (<i>S'</i>)

Setting up replication with two channels is not radically different from setting up a single replication channel. First, the `mysqld` processes for the primary and secondary replication masters must be started, followed by those for the primary and secondary slaves. Then the replication processes may be initiated by issuing the `START SLAVE` statement on each of the slaves. The commands and the order in which they need to be issued are shown here:

1. Start the primary replication master:

```
shellM> mysqld --ndbcluster --server-id=1 \
            --log-bin --binlog-format=row &
```

2. Start the secondary replication master:

```
shellM'> mysqld --ndbcluster --server-id=2 \
            --log-bin --binlog-format=row &
```

3. Start the primary replication slave server:

```
shellS> mysqld --ndbcluster --server-id=3 \
            --skip-slave-start &
```

4. Start the secondary replication slave:

```
shellS'> mysqld --ndbcluster --server-id=4 \
            --skip-slave-start &
```

5. Finally, commence replication on the primary channel by executing the `START SLAVE` statement on the primary slave as shown here:

```
mysqlS> START SLAVE;
```

As mentioned previously, it is not necessary to enable binary logging on replication slaves.

15.10.8. Implementing Failover with MySQL Cluster

In the event that the primary Cluster replication process fails, it is possible to switch over to the secondary replication channel. The following procedure describes the steps required to accomplish this.

1. Obtain the time of the most recent global checkpoint (GCP). That is, you need to determine the

most recent epoch from the `apply_status` table on the slave cluster, which can be found using the following query:

```
mysqlS' > SELECT @latest:=MAX(epoch)
-> FROM cluster.apply_status;
```

2.

Using the information obtained from the query shown in Step 1, obtain the corresponding records from the `binlog_index` table on the master cluster as shown here:

```
mysqlM' > SELECT
-> @file:=SUBSTRING_INDEX(File, '/', -1),
-> @pos:=Position
-> FROM cluster.binlog_index
-> WHERE epoch > @latest
-> ORDER BY epoch ASC LIMIT 1;
```

These are the records saved on the master since the failure of the primary replication channel. We have employed a user variable `@latest` here to represent the value obtained in Step 1. Of course, it is not possible for one `mysqld` instance to access user variables set on another server instance directly. These values must be “plugged in” to the second query manually or in application code.

3. Now it is possible to synchronize the secondary channel by running the following query on the secondary slave server:

```
mysqlS' > CHANGE MASTER TO
-> MASTER_LOG_FILE='@file',
-> MASTER_LOG_POS=@pos;
```

Again we have employed user variables (in this case `@file` and `@pos`) to represent the values obtained in Step 2 and applied in Step 3; in practice these values must be inserted manually or using application code that can access both of the servers involved.

Note that `@file` is a string value such as `' / var/log/mysql/replication-master-bin.00001'` and so must be quoted when used in SQL or application code. However, the value represented by `@pos` must *not* be quoted. Although MySQL normally attempts to convert strings to numbers, this case is an exception.

4. You can now initiate replication on the secondary channel by issuing the appropriate command on the secondary slave `mysqld`:

```
mysqlS' > START SLAVE;
```

Once the secondary replication channel is active, you can investigate the failure of the primary and effect repairs. The precise actions required to do this will depend upon the reasons for which the primary channel failed.

If the failure is limited to a single server, it should (in theory) be possible to replicate from *M* to *S'*, or from *M'* to *S*; however, this has not yet been tested.

15.10.9. MySQL Cluster Backups With Replication

This section discusses making backups and restoring from them using MySQL Cluster replication. We assume that the replication servers have already been configured as covered previously (see [Section 15.10.5, “Preparing the Cluster for Replication”](#), and the sections immediately following). This having been done, the procedure for making a backup and then restoring from it is as follows:

1. There are two different methods by which the backup may be started.

- **Method A:**

This method requires that the cluster backup process was previously enabled on the master server, prior to starting the replication process. This can be done by including the line

```
ndb-connectstring=management_host[:port]
```

in a `[MYSQL_CLUSTER]` section in the `my.cnf` file, where `management_host` is the IP address or hostname of the NDB management server for the master cluster, and `port` is the management server's port number. Note that the port number needs to be specified only if the default port (1186) is not being used. (See [Section 15.3.3, "Multi-Computer Configuration"](#), for more information about ports and port allocation in MySQL Cluster.)

In this case, the backup can be started by executing this statement on the replication master:

```
shellM> ndb_mgm -e "START BACKUP"
```

- **Method B:**

If the `my.cnf` file does not specify where to find the management host, you can start the backup process by passing this information to the NDB management client as part of the `START BACKUP` command, like this:

```
shellM> ndb_mgm management_host:port -e "START BACKUP"
```

where `management_host` and `port` are the hostname and port number of the management server. In our scenario as outlined earlier (see [Section 15.10.5, "Preparing the Cluster for Replication"](#)), this would be executed as follows:

```
shellM> ndb_mgm rep-master:1186 -e "START BACKUP"
```

In either case, it is highly advisable to allow any pending transactions to be completed before beginning the backup, and then not to permit any new transactions to begin during the backup process.

2. Copy the cluster backup files to the slave that is being brought on line. Each system running an `ndbd` process for the master cluster will have cluster backup files located on it, and *all* of these files must be copied to the slave to ensure a successful restore. The backup files can be copied into any directory on the computer where the slave management host resides, so long as the MySQL and NDB binaries have read permissions in that directory. In this case, we will assume that these files have been copied into the directory `/var/BACKUPS/BACKUP-1`.

It is not necessary that the slave cluster have the same number of `ndbd` processes (data nodes) as the master; however, it is highly recommended this number be the same. It is necessary that the slave be started with the `--skip-slave-start` option, to prevent premature startup of the replication process.

3. Create any databases on the slave cluster that are present on the master cluster that are to be replicated to the slave. **Important:** A `CREATE SCHEMA` statement corresponding to each database to be replicated must be executed on each data node in the slave cluster.
4. Reset the slave cluster using this statement in the MySQL Monitor:

```
mysqlS> RESET SLAVE;
```

It is important to make sure that the slave's `apply_status` table does not contain any records prior to running the restore process. You can accomplish this by running this SQL statement on the slave:

```
mysqlS> DELETE FROM cluster.apply_status;
```

5. You can now start the cluster restoration process on the replication slave using the `ndb_restore` command for each backup file in turn. For the first of these, it is necessary to include the `-m` option to restore the cluster metadata:

```
shellS> ndb_restore -c slave_host:port -n node-id \
          -b backup-id -m -r dir
```

`dir` is the path to the directory where the backup files have been placed on the replication slave. For the `ndb_restore` commands corresponding to the remaining backup files, the `-m` option should *not* be used.

For restoring from a master cluster with four data nodes (as shown in the figure in [Section 15.10, “MySQL Cluster Replication”](#)) where the backup files have been copied to the directory `/var/BACKUPS/BACKUP-1`, the proper sequence of commands to be executed on the slave might look like this:

```
shellS> ndb_restore -c rep-slave:1186 -n 2 -b 1 -m \
          -r ./VAR/BACKUPS/BACKUP-1
shellS> ndb_restore -c rep-slave:1186 -n 3 -b 1 \
          -r ./VAR/BACKUPS/BACKUP-1
shellS> ndb_restore -c rep-slave:1186 -n 4 -b 1 \
          -r ./VAR/BACKUPS/BACKUP-1
shellS> ndb_restore -c rep-slave:1186 -n 5 -b 1 -e \
          -r ./VAR/BACKUPS/BACKUP-1
```

This sequence of commands causes the most recent epoch records to be written to the slave's `apply_status` table.

6. Now you need to obtain the most recent epoch from the `binlog_index` table on the slave (as discussed in [Section 15.10.8, “Implementing Failover with MySQL Cluster”](#)):

```
mysqlS> SELECT @latest:=MAX(epoch)
          FROM cluster.apply_status;
```

7. Using `@latest` as the epoch value obtained in the previous step, you can obtain the correct starting position `@pos` in the correct binary logfile `@file` from the master's `cluster.binlog_index` table using the query shown here:

```
mysqlM> SELECT
->   @file:=SUBSTRING_INDEX(File, '/', -1),
->   @pos:=Position
-> FROM cluster.binlog_index
-> WHERE epoch > @latest
-> ORDER BY epoch ASC LIMIT 1;
```

8. Using the values obtained in the previous step, you can now issue the appropriate `CHANGE MASTER TO` statement in the slave's `mysql` client:

```
mysqlS> CHANGE MASTER TO
->   MASTER_LOG_FILE=@file',
->   MASTER_LOG_POS=@pos;
```

9. Now that the slave “knows” from what point in which `binlog` file to start reading data from the master, you can cause the slave to begin replicating with this standard MySQL statement:

```
mysqlS> START SLAVE;
```

To perform a backup and restore on a second replication channel, it is necessary only to repeat these steps, substituting the hostnames and IDs of the secondary master and slave for those of the primary master and slave replication servers where appropriate, and running the preceding statements on them.

For additional information on performing Cluster backups and restoring Cluster from backups, see [Section 15.8, “On-line Backup of MySQL Cluster”](#).

15.10.9.1. Automating Synchronization of the Slave to the Master bin-log

It is possible to automate much of the process described in the previous section (see [Section 15.10.9, “MySQL Cluster Backups With Replication”](#)). The following Perl script `reset-slave.pl` serves as an example of how you can do this.

```
#!/user/bin/perl -w

        MASTER_LOG_POS=$binpos;")
    or die "Prepare to CHANGE MASTER error: ", $dbhS->errstr;

    $sth->execute
    or die "CHNAGE MASTER on slave error: ", $sth->errstr;
    $sth->finish;
    print "\tSlave has been updated. You may now start the slave.\n";
}

# end reset-slave.pl

```

15.10.9.2. Initiating Discovery of Schema Changes

The NDB Cluster storage engine does not at present automatically detect structural changes in databases or tables. When a database or table is created or dropped, or when a table is altered using [ALTER TABLE](#), the cluster must be made aware of the change. When a database is created or dropped, the appropriate [CREATE SCHEMA](#) or [DROP SCHEMA](#) statement should be issued on each data node in the cluster to induce discovery of the change, that is:

```

mysqlS* > CREATE SCHEMA db_name;
mysqlS* > DROP SCHEMA db_name;

```

Dropping Tables:

When dropping a table that uses the [NDB Cluster](#) storage engine, it is necessary to allow any unfinished transactions to be completed and then not to begin any new transactions before performing the DROP operation:

1. Stop performing transactions on the slave.
2. Drop the table:

```

mysqlS > DROP TABLE [db_name.]table_name;

```

3. Make all slave `mysqld` processes aware of the drop:

```
mysqlS*> SHOW TABLES [FROM db_name];
```

All of the MySQL slave servers can now “see” that the table has been dropped from the database.

Creating Tables

When creating a new table, you should perform the following steps:

1. Create the table:

```
mysqlS> CREATE TABLE [db_name.]table_name (  
-> # column and index definitions...  
-> ) ENGINE=NDB;
```

2. Make all SQL nodes in the slave cluster aware of the new table:

```
mysqlS*> SHOW TABLES [FROM db_name];
```

You can now start using the table as normal. When creating a new table, note that — unlike the case when dropping tables — it is *not* necessary to stop performing any transactions beforehand.

Altering tables

When altering tables, you should perform the following steps in the order shown:

1. Ensure that all pending transactions have been completed, and do not initiate any new transactions at this time.
2. Issue any desired `ALTER TABLE` statements that add or remove columns to or from an existing table. For example:

```
mysqlS> ALTER TABLE table_name /* column definition, ... */;
```

3. Force all slave SQL nodes to become aware of the changed table definition. The recommended way to do this is by issuing a “throwaway” `SHOW TABLES` statement on each slave `mysqld`:

```
mysqlS*> SHOW TABLES;
```

You may now resume normal operations. These include transactions involving records in the changed table.

15.11. MySQL Cluster Disk Data Storage

In MySQL 5.1.6, it became possible to store the non-indexed columns of `NDB` tables on disk, rather than in RAM as with previous versions of MySQL Cluster.

As part of implementing Cluster Disk Data work, a number of improvements were made in MySQL Cluster for the efficient handling of very large amounts (terabytes) of data during node recovery and restart. These include a “no-steal” algorithm for synchronising a starting node with very large data sets. For more information, see the paper [Recovery Principles of MySQL Cluster 5.1](#)

[<http://www.vldb2005.org/program/paper/wed/p1108-ronstrom.pdf>], by MySQL Cluster developers Mikael Ronström and Jonas Orelund.

Assuming that you have already set up a MySQL Cluster with all nodes (including management and SQL nodes) running MySQL 5.1.6 or newer, the basic steps for creating a Cluster table on disk are as follows:

1. Create a *logfile group*, and assign one or more **UNDO** logfiles to it (an **UNDO** logfile is also referred as an **UNDOFILE**).
2. Create a *tablespace*, and assign the logfile group to it, as well as one or more datafiles.
3. Create a Disk Data table that uses this tablespace for data storage.

Each of these tasks can be accomplished using SQL statements, as shown in the following example.

1. We create a logfile group named `lg_1` using **CREATE LOGFILE GROUP**. This logfile group is to be made up of two **UNDO** logfiles, which we name `undo_1.dat` and `undo_2.dat`, whose initial sizes are 16 MB and 12 MB, respectively. (You must specify a logfile's initial size when adding it to a logfile group.) Optionally, you can also specify a size for the logfile group's **UNDO** buffer, or allow it to assume the default value of 8 MB. In this example, we set the **UNDO** buffer's size at 2 MB. A logfile group must be created with an **UNDO** logfile; so we add `undo_1.dat` to `lg_1` in this **CREATE LOGFILE GROUP** statement:

```
CREATE LOGFILE GROUP lg_1
  ADD UNDOFILE 'undo_1.dat'
  INITIAL_SIZE 16M
  UNDO_BUFFER_SIZE 2M
ENGINE NDB;
```

To add `undo_2.dat` to the logfile group, use the following **ALTER LOGFILE GROUP** statement:

```
ALTER LOGFILE GROUP lg_1
  ADD UNDOFILE 'undo_2.dat'
  INITIAL_SIZE 12M
ENGINE NDB;
```

Some items of note:

- The `.dat` file extension used here is not required. We use it merely to make the log and data files easily recognisable.
- Every **CREATE LOGFILE GROUP** and **ALTER LOGFILE GROUP** statement must include an **ENGINE** clause. In MySQL 5.1, the permitted values for this clause are **NDB** and **NDB-CLUSTER**.

Important: In MySQL 5.1.8 and later, there can exist only one logfile group at any given time.

- When you add an **UNDO** log file to a logfile group using **ADD UNDOFILE 'filename'**, a file with the the name `filename` is created in the `ndb_nodeid_fs` directory within the **DataDirectory** of each data node in the cluster, where `nodeid` is the node ID of the data node.
- **UNDO_BUFFER_SIZE** is limited by the amount of system memory available.
- For more information about the **CREATE LOGFILE GROUP** statement, see [Section 13.1.8](#),

[CREATE LOGFILE GROUP Syntax](#)". For more information about [ALTER LOGFILE GROUP](#), see [Section 13.1.3, "ALTER LOGFILE GROUP Syntax"](#).

2.

Now we can create a tablespace. A tablespace contains files to be used by MySQL Cluster Disk Data tables for storing their data. A tablespace is also associated with a particular logfile group. When creating a new tablespace, you must specify the logfile group which it is to use for [UNDO](#) logging; you must also specify a datafile. You can add more datafiles to the tablespace after it the tablespace is created; it is also possible to drop datafiles from a tablespace (an example of dropping datafiles is provided later in this section).

Assume that we wish to create a tablespace named `ts_1` which uses `lg_1` as its logfile group. This tablespace is to contain two datafiles named `data_1.dat` and `data_2.dat`, whose initial sizes are 32 MB and 48 MB, respectively. We can do this using two SQL statements: [CREATE TABLESPACE](#), to create `ts_1` with the datafile `data_1.dat`, and to associate `ts_1` with logfile group `lg_1`; and [ALTER TABLESPACE](#), to add the second datafile. We show these statements here:

```
CREATE TABLESPACE ts_1
  ADD DATAFILE 'data_1.dat'
  USE LOGFILE GROUP lg_1
  INITIAL_SIZE 32M
  ENGINE NDB;

ALTER TABLESPACE ts_1
  ADD DATAFILE 'data_2.dat'
  INITIAL_SIZE 48M
  ENGINE NDB;
```

Some items of note:

- As is the case with the filenames used here for [UNDO](#) logfiles, there is no special significance for the `.dat` file extension; it is used merely for easy recognition.
- All [CREATE TABLESPACE](#) and [ALTER TABLESPACE](#) statements must contain an [ENGINE](#) clause; only tables using the same storage engine as the tablespace can be created in the tablespace. In MySQL 5.1, the only permitted values for this clause are [NDB](#) and [NDBCLUSTER](#).

For more information about the [CREATE TABLESPACE](#) and [ALTER TABLESPACE](#) statements, see [Section 13.1.9, "CREATE TABLESPACE Syntax"](#), and [Section 13.1.4, "ALTER TABLESPACE Syntax"](#).

3.

Now it is possible to create a table whose non-indexed columns are stored on disk in the tablespace `ts_1`:

```
CREATE TABLE dt_1 (
  member_id INT UNSIGNED NOT NULL AUTO_INCREMENT PRIMARY KEY,
  last_name VARCHAR(50) NOT NULL,
  first_name VARCHAR(50) NOT NULL,
  dob DATE NOT NULL,
  joined DATE NOT NULL,
  INDEX(last_name, first_name)
)
TABLESPACE ts_1 STORAGE DISK
ENGINE NDB;
```

The [TABLESPACE ... STORAGE DISK](#) clause tells the [NDB Cluster](#) storage engine to use tablespace `ts_1` for disk data storage.

Once table `ts_1` has been created as shown, you can perform [INSERT](#), [SELECT](#), [UPDATE](#), and [DELETE](#) statements on it just as you would with any other MySQL table.

For table `dt_1` as it has been defined here, only the `dob` and `joined` columns are stored on disk. This is because there are indexes on the `id`, `last_name`, and `first_name` columns, and so data belonging to these columns is stored in RAM. In MySQL 5.1, only non-indexed columns can be held on disk; indexes and indexed column data continue to be stored in memory. This trade-off between the use of indexes and conservation of RAM is something you must keep in mind as you design Disk Data tables.

Important: For Disk Data tables in MySQL 5.1, variable-length columns take up a fixed amount of space. For each row, this is equal to the space required to store the largest possible value for that column. (For help in calculating these values, see [Section 11.5, “Data Type Storage Requirements”](#).)

Note: Starting the cluster with the `--initial` option does not remove Disk Data files. You must do so manually prior to performing an initial restart of the cluster.

A logfile group, a tablespace, and any Disk Data tables using these must be created in a particular order. The same is true for dropping any of these objects:

- A logfile group cannot be dropped, so long as any tablespaces are using it.
- A tablespace cannot be dropped, so long as it contains any datafiles.
- You cannot drop any datafiles from a tablespace, so long as there remain any tables which are using the tablespace.
- Beginning with MySQL 5.1.12, it is no longer possible to drop files created in association with a different tablespace than the one with which the files were created. ([Bug#20053](http://bugs.mysql.com/20053) [<http://bugs.mysql.com/20053>])

For example, to drop all the objects created so far in this section, you would use the following statements:

```
mysql> DROP TABLE dt_1;

mysql> ALTER TABLESPACE ts_1
-> DROP DATAFILE 'data_2.dat'
-> ENGINE NDB;

mysql> ALTER TABLESPACE ts_1
-> DROP DATAFILE 'data_1.dat'
-> ENGINE NDB;

mysql> DROP TABLESPACE ts_1
-> ENGINE NDB;

mysql> DROP LOGFILE GROUP lg_1
-> ENGINE NDB;
```

These statements must be performed in the order shown, except that the two `ALTER TABLESPACE ... DROP DATAFILE` statements may be executed in either order.

You can obtain information about UNDO logfiles and data files used by Disk Data tables by querying the `FILES` table in the `INFORMATION_SCHEMA` database. For more information, see [Section 22.21, “The INFORMATION_SCHEMA FILES Table”](#).

Configuration parameters affecting Disk Data behaviour include the following:

-

DiskPageBufferMemory

This determines the amount of space used for caching pages on disk, and is set in the `[NDBD]` or `[NDBD DEFAULT]` section of the `config.ini` file. It is measured in bytes. Each page takes up 32k. This means that Cluster Disk Data storage always uses $N * 32k$ memory where N is some non-negative integer.

•

SharedGlobalMemory

This determines the amount of memory that is used for log buffers, disk operations (such as page requests and wait queues), and metadata for tablespaces, logfile groups, UNDO files, and datafiles. It can be set in the `[NDBD]` or `[NDBD DEFAULT]` section of the `config.ini` configuration file, and is measured in bytes.

15.12. Using High-Speed Interconnects with MySQL Cluster

Even before design of `NDB Cluster` began in 1996, it was evident that one of the major problems to be encountered in building parallel databases would be communication between the nodes in the network. For this reason, `NDB Cluster` was designed from the very beginning to allow for the use of a number of different data transport mechanisms. In this Manual, we use the term *transporter* for these.

The MySQL Cluster codebase includes support for four different transporters:

- *TCP/IP using 100 Mbps or gigabit Ethernet*, as discussed in [Section 15.4.4.7, “Cluster TCP/IP Connections”](#).
- *Direct (machine-to-machine) TCP/IP*; although this transporter uses the same TCP/IP protocol as mentioned in the previous item, it requires setting up the hardware differently and is configured differently as well. For this reason, it is considered a separate transport mechanism for MySQL Cluster. See [Section 15.4.4.8, “TCP/IP Connections Using Direct Connections”](#), for details.
- *Shared memory (SHM)*. For more information about SHM, see [Section 15.4.4.9, “Shared-Memory Connections”](#).
- *Scalable Coherent Interface (SCI)*, as described in the next section of this chapter, [Section 15.4.4.10, “SCI Transport Connections”](#).

Most users today employ TCP/IP over Ethernet because it is ubiquitous. TCP/IP is also by far the best-tested transporter for use with MySQL Cluster.

We are working to make sure that communication with the `ndbd` process is made in “chunks” that are as large as possible because this benefits all types of data transmission.

For users who desire it, it is also possible to use cluster interconnects to enhance performance even further. There are two ways to achieve this: Either a custom transporter can be designed to handle this case, or you can use socket implementations that bypass the TCP/IP stack to one extent or another. We have experimented with both of these techniques using the SCI (Scalable Coherent Interface) technology developed by [Dolphin](http://www.dolphinics.com/) [<http://www.dolphinics.com/>].

15.12.1. Configuring MySQL Cluster to use SCI Sockets

In this section, we show how to adapt a cluster configured for normal TCP/IP communication to use SCI Sockets instead. This documentation is based on SCI Sockets version 2.3.0 as of 01 October 2004.

Prerequisites

Any machines with which you wish to use SCI Sockets must be equipped with SCI cards.

It is possible to use SCI Sockets with any version of MySQL Cluster. No special builds are needed because it uses normal socket calls which are already available in MySQL Cluster. However, SCI Sockets are currently supported only on the Linux 2.4 and 2.6 kernels. SCI Transporters have been tested successfully on additional operating systems although we have verified these only with Linux 2.4 to date.

There are essentially four requirements for SCI Sockets:

- Building the SCI Socket libraries.
- Installation of the SCI Socket kernel libraries.
- Installation of one or two configuration files.
- The SCI Socket kernel library must be enabled either for the entire machine or for the shell where the MySQL Cluster processes are started.

This process needs to be repeated for each machine in the cluster where you plan to use SCI Sockets for inter-node communication.

Two packages need to be retrieved to get SCI Sockets working:

- The source code package containing the DIS support libraries for the SCI Sockets libraries.
- The source code package for the SCI Socket libraries themselves.

Currently, these are available only in source code format. The latest versions of these packages at the time of this writing were available as (respectively) [DIS_GPL_2_5_0_SEP_10_2004.tar.gz](#) and [SCI_SOCKET_2_3_0_OKT_01_2004.tar.gz](#). You should be able to find these (or possibly newer versions) at <http://www.dolphinics.no/support/downloads.html>.

Package Installation

Once you have obtained the library packages, the next step is to unpack them into appropriate directories, with the SCI Sockets library unpacked into a directory below the DIS code. Next, you need to build the libraries. This example shows the commands used on Linux/x86 to perform this task:

```
shell> tar xzf DIS_GPL_2_5_0_SEP_10_2004.tar.gz
shell> cd DIS_GPL_2_5_0_SEP_10_2004/src/
shell> tar xzf ../../SCI_SOCKET_2_3_0_OKT_01_2004.tar.gz
shell> cd ../adm/bin/Linux_pkgs
shell> ./make_PSB_66_release
```

It is possible to build these libraries for some 64-bit processors. To build the libraries for Opteron CPUs using the 64-bit extensions, run [make_PSB_66_X86_64_release](#) rather than [make_PSB_66_release](#). If the build is made on an Itanium machine, you should use [make_PSB_66_IA64_release](#). The X86-64 variant should work for Intel EM64T architectures but this has not yet (to our knowledge) been tested.

Once the build process is complete, the compiled libraries will be found in a zipped tar file with a name

along the lines of `DIS-<operating-system>-time-date`. It is now time to install the package in the proper place. In this example we will place the installation in `/opt/DIS`. (**Note:** You will most likely need to run the following as the system `root` user.)

```
shell> cp DIS_Linux_2.4.20-8_181004.tar.gz /opt/  
shell> cd /opt  
shell> tar xzf DIS_Linux_2.4.20-8_181004.tar.gz  
shell> mv DIS_Linux_2.4.20-8_181004 DIS
```

Network Configuration

Now that all the libraries and binaries are in their proper place, we need to ensure that the SCI cards have proper node IDs within the SCI address space.

It is also necessary to decide on the network structure before proceeding. There are three types of network structures which can be used in this context:

- A simple one-dimensional ring
- One or more SCI switches with one ring per switch port
- A two- or three-dimensional torus.

Each of these topologies has its own method for providing node IDs. We discuss each of them in brief.

A simple ring uses node IDs which are non-zero multiples of 4: 4, 8, 12,...

The next possibility uses SCI switches. An SCI switch has 8 ports, each of which can support a ring. It is necessary to make sure that different rings use different node ID spaces. In a typical configuration, the first port uses node IDs below 64 (4 – 60), the next 64 node IDs (68 – 124) are assigned to the next port, and so on, with node IDs 452 – 508 being assigned to the eighth port.

Two- and three-dimensional torus network structures take into account where each node is located in each dimension, incrementing by 4 for each node in the first dimension, by 64 in the second dimension, and (where applicable) by 1024 in the third dimension. See [Dolphin's Web site](http://www.dolphinics.com/support/index.html) [http://www.dolphinics.com/support/index.html] for more thorough documentation.

In our testing we have used switches, although most large cluster installations use 2- or 3-dimensional torus structures. The advantage provided by switches is that, with dual SCI cards and dual switches, it is possible to build with relative ease a redundant network where the average failover time on the SCI network is on the order of 100 microseconds. This is supported by the SCI transporter in MySQL Cluster and is also under development for the SCI Socket implementation.

Failover for the 2D/3D torus is also possible but requires sending out new routing indexes to all nodes. However, this requires only 100 milliseconds or so to complete and should be acceptable for most high-availability cases.

By placing cluster data nodes properly within the switched architecture, it is possible to use 2 switches to build a structure whereby 16 computers can be interconnected and no single failure can hinder more than one of them. With 32 computers and 2 switches it is possible to configure the cluster in such a manner that no single failure can cause the loss of more than two nodes; in this case, it is also possible to know which pair of nodes is affected. Thus, by placing the two nodes in separate node groups, it is possible to build a “safe” MySQL Cluster installation.

To set the node ID for an SCI card use the following command in the `/opt/DIS/sbin` directory. In this example, `-c 1` refers to the number of the SCI card (this is always 1 if there is only 1 card in the machine); `-a 0` refers to adapter 0; and `68` is the node ID:

```
shell> ./sciconfig -c 1 -a 0 -n 68
```

If you have multiple SCI cards in the same machine, you can determine which card has which slot by issuing the following command (again we assume that the current working directory is `/opt/DIS/sbin`):

```
shell> ./sciconfig -c 1 -gsn
```

This will give you the SCI card's serial number. Then repeat this procedure with `-c 2`, and so on, for each card in the machine. Once you have matched each card with a slot, you can set node IDs for all cards.

After the necessary libraries and binaries are installed, and the SCI node IDs are set, the next step is to set up the mapping from hostnames (or IP addresses) to SCI node IDs. This is done in the SCI sockets configuration file, which should be saved as `/etc/sci/scisock.conf`. In this file, each SCI node ID is mapped through the proper SCI card to the hostname or IP address that it is to communicate with. Here is a very simple example of such a configuration file:

```
#host          #nodeId
alpha          8
beta           12
192.168.10.20  16
```

It is also possible to limit the configuration so that it applies only to a subset of the available ports for these hosts. An additional configuration file `/etc/sci/scisock_opt.conf` can be used to accomplish this, as shown here:

```
#-key          -type      -values
EnablePortsByDefault  yes
EnablePort        tcp        2200
DisablePort       tcp        2201
EnablePortRange    tcp        2202 2219
DisablePortRange    tcp        2220 2231
```

Driver Installation

With the configuration files in place, the drivers can be installed.

First, the low-level drivers and then the SCI socket driver need to be installed:

```
shell> cd DIS/sbin/
shell> ./drv-install add PSB66
shell> ./scisocket-install add
```

If desired, the installation can be checked by invoking a script which verifies that all nodes in the SCI socket configuration files are accessible:

```
shell> cd /opt/DIS/sbin/
shell> ./status.sh
```

If you discover an error and need to change the SCI socket configuration, it is necessary to use `ksocket-etconfig` to accomplish this task:

```
shell> cd /opt/DIS/util
shell> ./ksocketconfig -f
```

Testing the Setup

To ensure that SCI sockets are actually being used, you can employ the `latency_bench` test pro-

gram. Using this utility's server component, clients can connect to the server to test the latency of the connection. Determining whether SCI is enabled should be fairly simple from observing the latency. (**Note:** Before using `latency_bench`, it is necessary to set the `LD_PRELOAD` environment variable as shown later in this section.)

To set up a server, use the following:

```
shell> cd /opt/DIS/bin/socket
shell> ./latency_bench -server
```

To run a client, use `latency_bench` again, except this time with the `-client` option:

```
shell> cd /opt/DIS/bin/socket
shell> ./latency_bench -client server_hostname
```

SCI socket configuration should now be complete and MySQL Cluster ready to use both SCI Sockets and the SCI transporter (see [Section 15.4.4.10](#), “SCI Transport Connections”).

Starting the Cluster

The next step in the process is to start MySQL Cluster. To enable usage of SCI Sockets it is necessary to set the environment variable `LD_PRELOAD` before starting `ndbd`, `mysqld`, and `ndb_mgmd`. This variable should point to the kernel library for SCI Sockets.

To start `ndbd` in a bash shell, do the following:

```
bash-shell> export LD_PRELOAD=/opt/DIS/lib/libkscisock.so
bash-shell> ndbd
```

In a tcsh environment the same thing can be accomplished with:

```
tcsh-shell> setenv LD_PRELOAD=/opt/DIS/lib/libkscisock.so
tcsh-shell> ndbd
```

Note: MySQL Cluster can use only the kernel variant of SCI Sockets.

15.12.2. Understanding the Impact of Cluster Interconnects

The `ndbd` process has a number of simple constructs which are used to access the data in a MySQL Cluster. We have created a very simple benchmark to check the performance of each of these and the effects which various interconnects have on their performance.

There are four access methods:

- **Primary key access**

This is access of a record through its primary key. In the simplest case, only one record is accessed at a time, which means that the full cost of setting up a number of TCP/IP messages and a number of costs for context switching are borne by this single request. In the case where multiple primary key accesses are sent in one batch, those accesses share the cost of setting up the necessary TCP/IP messages and context switches. If the TCP/IP messages are for different destinations, additional TCP/IP messages need to be set up.

- **Unique key access**

Unique key accesses are similar to primary key accesses, except that a unique key access is executed as a read on an index table followed by a primary key access on the table. However, only one request is sent from the MySQL Server, and the read of the index table is handled by `ndbd`. Such requests

also benefit from batching.

- **Full table scan**

When no indexes exist for a lookup on a table, a full table scan is performed. This is sent as a single request to the `ndbd` process, which then divides the table scan into a set of parallel scans on all cluster `ndbd` processes. In future versions of MySQL Cluster, an SQL node will be able to filter some of these scans.

- **Range scan using ordered index**

When an ordered index is used, it performs a scan in the same manner as the full table scan, except that it scans only those records which are in the range used by the query transmitted by the MySQL server (SQL node). All partitions are scanned in parallel when all bound index attributes include all attributes in the partitioning key.

To check the base performance of these access methods, we have developed a set of benchmarks. One such benchmark, `testReadPerf`, tests simple and batched primary and unique key accesses. This benchmark also measures the setup cost of range scans by issuing scans returning a single record. There is also a variant of this benchmark which uses a range scan to fetch a batch of records.

In this way, we can determine the cost of both a single key access and a single record scan access, as well as measure the impact of the communication media used, on base access methods.

In our tests, we ran the base benchmarks for both a normal transporter using TCP/IP sockets and a similar setup using SCI sockets. The figures reported in the following table are for small accesses of 20 records per access. The difference between serial and batched access decreases by a factor of 3 to 4 when using 2KB records instead. SCI Sockets were not tested with 2KB records. Tests were performed on a cluster with 2 data nodes running on 2 dual-CPU machines equipped with AMD MP1900+ processors.

Access Type	TCP/IP Sockets	SCI Socket
Serial pk access	400 microseconds	160 microseconds
Batched pk access	28 microseconds	22 microseconds
Serial uk access	500 microseconds	250 microseconds
Batched uk access	70 microseconds	36 microseconds
Indexed eq-bound	1250 microseconds	750 microseconds
Index range	24 microseconds	12 microseconds

We also performed another set of tests to check the performance of SCI Sockets *vis-à-vis* that of the SCI transporter, and both of these as compared with the TCP/IP transporter. All these tests used primary key accesses either serially and multi-threaded, or multi-threaded and batched.

The tests showed that SCI sockets were about 100% faster than TCP/IP. The SCI transporter was faster in most cases compared to SCI sockets. One notable case occurred with many threads in the test program, which showed that the SCI transporter did not perform very well when used for the `mysqld` process.

Our overall conclusion was that, for most benchmarks, using SCI sockets improves performance by approximately 100% over TCP/IP, except in rare instances when communication performance is not an issue. This can occur when scan filters make up most of processing time or when very large batches of primary key accesses are achieved. In that case, the CPU processing in the `ndbd` processes becomes a fairly large part of the overhead.

Using the SCI transporter instead of SCI Sockets is only of interest in communicating between `ndbd`

processes. Using the SCI transporter is also only of interest if a CPU can be dedicated to the `ndbd` process because the SCI transporter ensures that this process will never go to sleep. It is also important to ensure that the `ndbd` process priority is set in such a way that the process does not lose priority due to running for an extended period of time, as can be done by locking processes to CPUs in Linux 2.6. If such a configuration is possible, the `ndbd` process will benefit by 10–70% as compared with using SCI sockets. (The larger figures will be seen when performing updates and probably on parallel scan operations as well.)

There are several other optimized socket implementations for computer clusters, including Myrinet, Gigabit Ethernet, Infiniband and the VIA interface. We have tested MySQL Cluster so far only with SCI sockets. See [Section 15.12.1, “Configuring MySQL Cluster to use SCI Sockets”](#) for information on how to set up SCI sockets using ordinary TCP/IP for MySQL Cluster.

15.13. Known Limitations of MySQL Cluster

In this section, we provide a list of known limitations in MySQL Cluster releases in the 5.1.x series compared to features available when using the `MyISAM` and `InnoDB` storage engines. Currently, there are no plans to address these in coming releases of MySQL 5.1; however, we will attempt to supply fixes for these issues in subsequent release series. If you check the “Cluster” category in the MySQL bugs database at <http://bugs.mysql.com>, you can find known bugs which (if marked “5.1”) we intend to correct in upcoming releases of MySQL 5.1.

The list here is intended to be complete with respect to the conditions just set forth. You can report any discrepancies that you encounter to the MySQL bugs database using the instructions given in [Section 1.8, “How to Report Bugs or Problems”](#). If we do not plan to fix the problem in MySQL 5.1, we will add it to the list.

(**Note:** See the end of this section for a list of issues in MySQL 5.0 Cluster that have been resolved in the current version.)

Limitations and other issues specific to MySQL Cluster Replication are described in [Section 15.10.3, “Known Issues”](#).

- **Noncompliance in syntax** (resulting in errors when running existing applications):
 - Temporary tables are not supported.
 - Text indexes are not supported. That is, you cannot create indexes on columns of any of the `TEXT` datatypes, nor does the `NDB` storage engine support `FULLTEXT` indexes (these are supported by `MyISAM` only). However, you can index `VARCHAR` columns of `NDB` tables.
 - A `BIT` column cannot be a primary key, unique key, or index, nor can it be part of a composite primary key, unique key, or index.
 - Geometry datatypes (`WKT` and `WKB`) are supported in `NDB` tables in MySQL 5.1. However, spatial indexes are not supported.
 - `CREATE TABLE` statements may be no more than 4096 characters in length. *This limitation affects MySQL 5.1.6, 5.1.7, and 5.1.8 only.* (See [Bug#17813](#) [<http://bugs.mysql.com/17813>])
 - In MySQL 5.1.7 and earlier, `INSERT IGNORE`, `UPDATE IGNORE`, and `REPLACE` are supported only for primary keys, but not for unique keys. One possible workaround is to remove the constraint by dropping the unique index, perform any inserts, and then add the unique index again.

This limitation is removed for `INSERT IGNORE` and `REPLACE` in MySQL 5.1.8. ([Bug#17431](#))

[<http://bugs.mysql.com/17431>])

- Support for user-defined partitioning for MySQL Cluster in MySQL 5.1 is restricted to [\[LINEAR\] KEY](#) partitioning. Beginning with MySQL 5.1.12, using any other partitioning type with [ENGINE=NDB](#) or [ENGINE=NDBCLUSTER](#) in a [CREATE TABLE](#) statement results in an error.

As of MySQL 5.1.6, all Cluster tables are by default partitioned by [KEY](#) using the table's primary key as the partitioning key. If no primary key is explicitly set for the table, the “hidden” primary key automatically created by the [NDB](#) storage engine is used instead. For additional discussion of these and related issues, see [Section 16.2.4, “KEY Partitioning”](#).

It is not possible to drop partitions from [NDB](#) tables using [ALTER TABLE ... DROP PARTITION](#). The other partitioning extensions to [ALTER TABLE](#) — [ADD PARTITION](#), [REORGANIZE PARTITION](#), and [COALESCE PARTITION](#) — are supported for Cluster tables, but use copying and so are not optimised. See [Section 16.3.1, “Management of RANGE and LIST Partitions”](#) and [Section 13.1.2, “ALTER TABLE Syntax”](#).

- When using row-based replication with MySQL Cluster, binary logging cannot be disabled. That is, the [NDB](#) storage engine ignores the value of [SQL_LOG_BIN](#). ([Bug#16680](#) [<http://bugs.mysql.com/16680>])
- The [auto_increment_increment](#) and [auto_increment_offset](#) server system variables are not supported for Cluster replication.

- **Non-compliance in limits or behavior** (may result in errors when running existing applications):

- **Memory Usage:**

Memory consumed when data is inserted into an [NDB](#) table is not automatically recovered when deleted, as it is with other storage engines. Instead, the following rules hold true:

- A [DELETE](#) statement on an [NDB](#) table makes the memory formerly used by the deleted rows available for re-use by inserts on the same table only. The memory cannot be used by other [NDB](#) tables.
- A [DROP TABLE](#) or [TRUNCATE](#) operation on an [NDB](#) table frees the memory that was used by this table for re-use by any [NDB](#) table — either by the same table or by another [NDB](#) table.

(Recall that [TRUNCATE](#) drops and re-creates the table. See [Section 13.2.9, “TRUNCATE Syntax”](#).)

Memory freed by [DELETE](#) operations but still allocated to a specific table can also be made available for general re-use by performing a rolling restart of the cluster. See [Section 15.5.1, “Performing a Rolling Restart of the Cluster”](#).

- **Error Reporting:**

- A duplicate key error returns the error message `ERROR 23000: Can't write; duplicate key in table 'tbl_name'`.
- Like other MySQL storage engines, the [NDB](#) storage engine can handle a maximum of one [AUTO_INCREMENT](#) column per table. However, in the case of a Cluster table with no explicit primary key, an [AUTO_INCREMENT](#) column is automatically defined and used as a “hidden” primary key. For this reason, you cannot define a table that has an explicit

`AUTO_INCREMENT` column unless that column is also declared using the `PRIMARY KEY` option.

Attempting to create a table with an `AUTO_INCREMENT` column that is not the table's primary key, and using the `NDB` storage engine, fails with an error.

- **Transaction Handling:**

- `NDB Cluster` supports only the `READ COMMITTED` transaction isolation level.
- There is no partial rollback of transactions. A duplicate key or similar error results in a rollback of the entire transaction.
- **Important:** If a `SELECT` from a Cluster table includes a `BLOB` or `TEXT` column, the `READ COMMITTED` transaction isolation level is converted to a read with read lock. This is done to guarantee consistency, due to the fact that parts of the values stored in columns of these types are actually read from a separate table.
- As noted elsewhere in this chapter, MySQL Cluster does not handle large transactions well; it is better to perform a number of small transactions with a few operations each than to attempt a single large transaction containing a great many operations.

Among other considerations, large transactions require very large amounts of memory. Because of this, the transactional behaviour of a number of MySQL statements is effected as described in the following list:

- `TRUNCATE` is not transactional when used on `NDB` tables. If a `TRUNCATE` fails to empty the table, then it must be re-run until it is successful.
- `DELETE FROM` (even with no `WHERE` clause) is transactional. For tables containing a great many rows, you may find that performance is improved by using several `DELETE FROM ... LIMIT ...` statements to “chunk” the delete operation. If the objective is to empty the table, then you may wish to use `TRUNCATE` instead.
- `LOAD DATA INFILE` is not transactional when used on `NDB` tables. *During such an operation, the `NDB` engine can and does commit at will.*

`LOAD DATA FROM MASTER` is not supported in MySQL Cluster.

- When copying a table as part of an `ALTER TABLE`, the creation of the copy is non-transactional. (In any case, this operation is rolled back when the copy is deleted.)
- **Node Start, Stop, or Restart:** Starting, stopping, or restarting a node may give rise to temporary errors causing some transactions to fail. These include the following cases:
 - When first starting a node, it is possible that you may see Error 1204 Temporary failure, distribution changed and similar temporary errors.
 - The stopping or failure of any data node can result in a number of different node failure errors. (However, there should be no aborted transactions when performing a planned shutdown of the cluster.)

In either of these cases, any errors that are generated must be handled within the application. This should be done by retrying the transaction.

-

A number of hard limits exist which are configurable, but available main memory in the cluster sets limits. See the complete list of configuration parameters in [Section 15.4.4, “Configuration File”](#). Most configuration parameters can be upgraded online. These hard limits include:

- Database memory size and index memory size ([DataMemory](#) and [IndexMemory](#), respectively).

[DataMemory](#) is allocated as 32KB pages. As each [DataMemory](#) page is used, it is assigned to a specific table; once allocated, this memory cannot be freed except by dropping the table.

See [Section 15.4.4.5, “Defining Data Nodes”](#), for further information about [DataMemory](#) and [IndexMemory](#).

- The maximum number of operations that can be performed per transaction is set using the configuration parameters [MaxNoOfConcurrentOperations](#) and [MaxNoOfLocalOperations](#). Note that bulk loading, `TRUNCATE TABLE`, and `ALTER TABLE` are handled as special cases by running multiple transactions, and so are not subject to this limitation.
- Different limits related to tables and indexes. For example, the maximum number of ordered indexes per table is determined by [MaxNoOfOrderedIndexes](#).

- Database names, table names and attribute names cannot be as long in [NDB](#) tables as with other table handlers. Attribute names are truncated to 31 characters, and if not unique after truncation give rise to errors. Database names and table names can total a maximum of 122 characters. (That is, the maximum length for an [NDB Cluster](#) table name is 122 characters less the number of characters in the name of the database of which that table is a part.)

- The maximum number of tables in a Cluster database is limited to 20320.
- In MySQL 5.1.10 and earlier versions, the maximum number of tables having [AUTO_INCREMENT](#) columns — including those belonging to hidden primary keys — is 2048.

This limitation was lifted in MySQL 5.1.11.

- The maximum number of attributes per table is limited to 128.
- The maximum permitted size of any one row is 8KB. Note that each [BLOB](#) or [TEXT](#) column contributes $256 + 8 = 264$ bytes towards this total.
- The maximum number of attributes per key is 32.

• **Unsupported features** (do not cause errors, but are not supported or enforced):

- The foreign key construct is ignored, just as it is in [MyISAM](#) tables.
- Savepoints and rollbacks to savepoints are ignored as in [MyISAM](#).
- [OPTIMIZE](#) operations are not supported.
- `LOAD TABLE . . . FROM MASTER` is not supported.

• **Performance and limitation-related issues:**

- There are query performance issues due to sequential access to the [NDB](#) storage engine; it is also relatively more expensive to do many range scans than it is with either [MyISAM](#) or [InnoDB](#).
- The [Records in range](#) statistic is available but not completely tested or officially supported. This may result in non-optimal query plans in some cases. If necessary, you can employ [USE INDEX](#) or [FORCE INDEX](#) for that purpose.
- Unique hash indexes created with [USING HASH](#) cannot be used for accessing a table if [NULL](#) is given as part of the key.
- MySQL Cluster does not support durable commits on disk. Commits are replicated, but there is no guarantee that logs are flushed to disk on commit.
- [SQL_LOG_BIN](#) has no effect on data operations; however, it is supported for schema operations.

MySQL Cluster cannot produce a binlog for tables having [BLOB](#) columns but no primary key.

Only the following schema operations are logged in a cluster binlog which is *not* on the `mysqld` executing the statement:

- [CREATE TABLE](#)
- [ALTER TABLE](#)
- [DROP TABLE](#)
- [CREATE DATABASE / CREATE SCHEMA](#)
- [DROP DATABASE / DROP SCHEMA](#)
- [CREATE TABLESPACE](#)
- [ALTER TABLESPACE](#)
- [DROP TABLESPACE](#)
- [CREATE LOGFILE GROUP](#)
- [ALTER LOGFILE GROUP](#)
- [DROP LOGFILE GROUP](#)

- **Missing features:**

- The only supported isolation level is [READ COMMITTED](#). (InnoDB supports [READ COMMITTED](#), [READ UNCOMMITTED](#), [REPEATABLE READ](#), and [SERIALIZABLE](#).) See [Section 15.8.5, “Backup Troubleshooting”](#), for information on how this can affect backup and restore of Cluster databases.
- No durable commits on disk. Commits are replicated, but there is no guarantee that logs are flushed to disk on commit.

- **Problems relating to multiple MySQL servers** (not relating to [MyISAM](#) or [InnoDB](#)):

- [ALTER TABLE](#) is not fully locking when running multiple MySQL servers (no distributed table lock).

- DDL operations are not node failure safe. If a node fails while trying to perform one of these (such as `CREATE TABLE` or `ALTER TABLE`), the data dictionary is locked and no further DDL statements can be executed without restarting the cluster.

- **Issues exclusive to MySQL Cluster** (not related to `MyISAM` or `InnoDB`):

- All machines used in the cluster must have the same architecture. That is, all machines hosting nodes must be either big-endian or little-endian, and you cannot use a mixture of both. For example, you cannot have a management node running on a PowerPC which directs a data node that is running on an x86 machine. This restriction does not apply to machines simply running `mysql` or other clients that may be accessing the cluster's SQL nodes.
- Online adding or dropping of nodes is not possible (the cluster must be restarted in such cases).
- While it is possible to run multiple cluster processes concurrently on a single host, it is not always advisable to do so for reasons of performance and high availability, as well as other considerations. In particular, we do not in MySQL 5.1 support for production use any MySQL Cluster deployment in which more than one `ndbd` process is run on a single physical machine.

We may support multiple data nodes per host in a future MySQL release, following additional testing. However, in MySQL 5.1, such configurations can be considered experimental only.

- Use of Disk Data tables is not supported when running the cluster in diskless mode. Beginning with MySQL 5.1.12, it is disallowed altogether. ([Bug#20008](http://bugs.mysql.com/20008) [<http://bugs.mysql.com/20008>])
- When using multiple management servers:
 - You must give nodes explicit IDs in connectstrings because automatic allocation of node IDs does not work across multiple management servers.
 - You must take extreme care to have the same configurations for all management servers. No special checks for this are performed by the cluster.

- Multiple network addresses per data node are not supported. Use of these is liable to cause problems: In the event of a data node failure, an SQL node waits for confirmation that the data node went down but never receives it because another route to that data node remains open. This can effectively make the cluster inoperable.

It is possible to use multiple network hardware interfaces (such as Ethernet cards) for a single data node, but these must be bound to the same address. This also means that it not possible to use more than one `[TCP]` section per connection in the `config.ini` file. See [Section 15.4.4.7, “Cluster TCP/IP Connections”](#), for more information.

- The maximum number of data nodes is 48.
- The total maximum number of nodes in a MySQL Cluster is 63. This number includes all SQL nodes (MySQL Servers), API nodes (applications accessing the cluster other than MySQL servers), data nodes, and management servers.
- The maximum number of metadata objects in MySQL 5.1 Cluster is 20320. This limit is hard-coded.

- **MySQL Cluster issues from previous versions that have been resolved in MySQL 5.1:**

- The `NDB Cluster` storage engine now supports variable-length column types for in-memory

tables.

Previously, this meant that — for example — any Cluster table having one or more `VARCHAR` fields which contained only relatively small values, much more memory and disk space were required when using the `NDBCluster` storage engine than would have been the case for the same table and data using the `MyISAM` engine. In other words, in the case of a `VARCHAR` column, such a column required the same amount of storage as a `CHAR` column of the same size. In MySQL 5.1, this is no longer the case for in-memory tables, where storage requirements for variable-length column types such as `VARCHAR` and `BINARY` are comparable to those for these column types when used in `MyISAM` tables (see [Section 11.5, “Data Type Storage Requirements”](#)).

Important: For MySQL Cluster Disk Data tables, the fixed-width limitation continues to apply. See [Section 15.11, “MySQL Cluster Disk Data Storage”](#).

- It is now possible to use MySQL replication with Cluster databases. For details, see [Section 15.10, “MySQL Cluster Replication”](#).

However, circular replication is *not* currently supported for MySQL Cluster. See [Section 15.10.3, “Known Issues”](#).

- Autodiscovery of databases is now supported for multiple MySQL servers accessing the same MySQL Cluster, provided that a given `mysqld` is already running and is connected to the cluster at the time that the database is created on a different `mysqld`.

What this means is that if a `mysqld` process first connects to the cluster after a database named `db_name` has been created, you should issue a `CREATE SCHEMA db_name` statement on the “new” MySQL server when it first accesses that MySQL Cluster. Once this has been done, the “new” `mysqld` should be able to detect any tables in that database tables without errors.

This also means that online schema changes in `NDB` tables are now possible. That is, the result of operations such as `ALTER TABLE` and `CREATE INDEX` performed on one SQL node in the cluster are now visible to the cluster's other SQL nodes without any additional action being taken.

- Beginning with MySQL 5.1.10, it is possible to perform a Cluster backup and restore between different architectures. Previously — for example — you could not back up a cluster running on a big-endian platform and then restore from that backup to a cluster running on a little-endian system. ([Bug#19255](#) [<http://bugs.mysql.com/19255>])
- Beginning with MySQL 5.1.10, it is possible to install MySQL with Cluster support to a non-default location and change the search path for font description files using either the `-basedir` or `--character-sets-dir` options. (Previously, `ndbd` in MySQL 5.1 searched only the default path — typically `/usr/local/mysql/share/mysql/charsets` — for character sets.)
- In MySQL 5.1, it is no longer necessary, when running multiple management servers, to restart all the cluster's data nodes to enable the management nodes to see one another.

15.14. MySQL Cluster Development Roadmap

In this section, we discuss changes in the implementation of MySQL Cluster in MySQL 5.1 as compared to MySQL 5.0.

There are a number of significant changes in the implementation of the [NDB Cluster](#) storage engine in MySQL 5.1 as compared to that in MySQL 5.0. For an overview of these changes, see [Section 15.14.1, “MySQL Cluster Changes in MySQL 5.1”](#)

15.14.1. MySQL Cluster Changes in MySQL 5.1

Four major new features for MySQL Cluster have been developed for MySQL 5.1:

1. **Integration of MySQL Cluster into MySQL replication:** This makes it possible to update from any MySQL Server in the cluster and still have the MySQL Replication handled by one of the MySQL Servers in the cluster, with the state of the slave side remaining consistent with the cluster acting as the master.

See [Section 15.10, “MySQL Cluster Replication”](#).
2. **Support for disk-based records:** Records on disk are now supported. Indexed fields including the primary key hash index must still be stored in RAM but all other fields can be on disk.

See [Section 15.11, “MySQL Cluster Disk Data Storage”](#).
3. **Variable-sized records:** A column defined as `VARCHAR(255)` currently uses 260 bytes of storage independent of what is stored in any particular record. In MySQL 5.1 Cluster tables, only the portion of the column actually taken up by the record will be stored. This will make possible a reduction in space requirements for such columns by a factor of 5 in many cases.
4. **User-defined partitioning:** Users can define partitions based on columns that are part of the primary key. It is possible to partition tables based on `KEY`, `HASH`, `RANGE`, and `LIST`, as is subpartitioning. This feature is also available for many other storage engines, and not only [NDB Cluster](#).

See [Chapter 16, Partitioning](#).

The MySQL Server can also determine whether it is possible to “prune away” some of the partitions from the `WHERE` clause. See [Section 16.4, “Partition Pruning”](#).

15.15. MySQL Cluster FAQ

This section answers questions that are often asked about MySQL Cluster.

- *What does “NDB” mean?*
This stands for “**N**etwork **D**atabase.”
- *What's the difference in using Cluster vs using replication?*

In a replication setup, a master MySQL server updates one or more slaves. Transactions are committed sequentially, and a slow transaction can cause the slave to lag behind the master. This means that if the master fails, it is possible that the slave might not have recorded the last few transactions. If a transaction-safe engine such as [InnoDB](#) is being used, a transaction will either be complete on the slave or not applied at all, but replication does not guarantee that all data on the master and the slave will be consistent at all times. In MySQL Cluster, all data nodes are kept in synchrony, and a transaction committed by any one data node is committed for all data nodes. In the event of a data node failure, all remaining data nodes remain in a consistent state.

In short, whereas standard MySQL replication is asynchronous, MySQL Cluster is synchronous.

We have implemented (asynchronous) replication for Cluster in MySQL 5.1. This includes the capability to replicate both between two clusters, and from a MySQL cluster to a non-Cluster MySQL server.

See [Section 15.10, “MySQL Cluster Replication”](#).

- *Do I need to do any special networking to run Cluster? (How do computers in a cluster communicate?)*

MySQL Cluster is intended to be used in a high-bandwidth environment, with computers connecting via TCP/IP. Its performance depends directly upon the connection speed between the cluster's computers. The minimum connectivity requirements for Cluster include a typical 100-megabit Ethernet network or the equivalent. We recommend you use gigabit Ethernet whenever available.

The faster SCI protocol is also supported, but requires special hardware. See [Section 15.12, “Using High-Speed Interconnects with MySQL Cluster”](#), for more information about SCI.

- *How many computers do I need to run a cluster, and why?*

A minimum of three computers is required to run a viable cluster. However, the minimum **recommended** number of computers in a MySQL Cluster is four: one each to run the management and SQL nodes, and two computers to serve as data nodes. The purpose of the two data nodes is to provide redundancy; the management node must run on a separate machine to guarantee continued arbitration services in the event that one of the data nodes fails.

- *What do the different computers do in a cluster?*

A MySQL Cluster has both a physical and logical organization, with computers being the physical elements. The logical or functional elements of a cluster are referred to as *nodes*, and a computer housing a cluster node is sometimes referred to as a *cluster host*. There are three types of nodes, each corresponding to a specific role within the cluster. These are:

- **Management node (MGM node):** Provides management services for the cluster as a whole, including startup, shutdown, backups, and configuration data for the other nodes. The management node server is implemented as the application `ndb_mgmd`; the management client used to control MySQL Cluster via the MGM node is `ndb_mgm`.
- **Data node:** Stores and replicates data. Data node functionality is handled by an instance of the NDB data node process `ndbd`.
- **SQL node:** This is simply an instance of MySQL Server (`mysqld`) that is built with support for the `NDB Cluster` storage engine and started with the `--ndb-cluster` option to enable the engine.

- *With which operating systems can I use Cluster?*

MySQL Cluster is supported on most Unix-like operating systems, including Linux, Mac OS X, Solaris, BSD, HP-UX, AIX, and IRIX, among others, as well as Novell Netware. Cluster is not supported for Windows at this time. However, we are working to add Cluster support for other platforms, including Windows, and our goal is to offer MySQL Cluster on all platforms for which MySQL itself is supported.

For more detailed information concerning the level of support which is offered for MySQL Cluster on various operating system versions, OS distributions, and hardware platforms, please refer to <http://www.mysql.com/support/supportedplatforms.html>.

- *What are the hardware requirements for running MySQL Cluster?*

Cluster should run on any platform for which NDB-enabled binaries are available. Naturally, faster CPUs and more memory will improve performance, and 64-bit CPUs will likely be more effective than 32-bit processors. There must be sufficient memory on machines used for data nodes to hold each node's share of the database (see *How much RAM do I Need?* for more information). Nodes can communicate via a standard TCP/IP network and hardware. For SCI support, special networking hardware is required.

- *How much RAM do I need? Is it possible to use disk memory at all?*

Previous to MySQL 5.1, Cluster was in-memory only. This meant that all table data (including indexes) was stored in RAM. If your data took up 1GB of space and you wanted to replicate it once in the cluster, you needed 2GB of memory to do so (1 GB per replica). This was in addition to the memory required by the operating system and any applications running on the cluster computers. This is still true of in-memory tables.

If a data node's memory usage exceeds what is available in RAM, then the system will attempt to use swap space up to the limit set for `DataMemory`. However, this will at best result in severely degraded performance, and may cause the node to be dropped due to slow response time (missed heartbeats). We do not recommend on relying on disk swapping in a production environment for this reason. In any case, once the `DataMemory` limit is reached, any operations requiring additional memory (such as inserts) will fail.

`NDB Cluster` in MySQL 5.1 includes support for Disk Data, which helps to alleviate these issues. See [Section 15.11, “MySQL Cluster Disk Data Storage”](#), for more information.

You can use the following formula for obtaining a rough estimate of how much RAM is needed for each data node in the cluster:

```
(SizeofDatabase × NumberOfReplicas × 1.1 ) / NumberOfDataNodes
```

To calculate the memory requirements more exactly requires determining, for each table in the cluster database, the storage space required per row (see [Section 11.5, “Data Type Storage Requirements”](#), for details), and multiplying this by the number of rows. You must also remember to account for any column indexes as follows:

- Each primary key or hash index created for an `NDBCluster` table requires 21–25 bytes per record. These indexes use `IndexMemory`.
- Each ordered index requires 10 bytes storage per record, using `DataMemory`.
- Creating a primary key or unique index also creates an ordered index, unless this index is created with `USING HASH`. In other words:
 - A primary key or unique index on a Cluster table normally takes up 31 to 35 bytes per record.
 - However, if the primary key or unique index is created with `USING HASH`, then it requires only 21 to 25 bytes per record.

Note that creating MySQL Cluster tables with `USING HASH` for all primary keys and unique in-

dexes will generally cause table updates to run more quickly — in some cases by as much as 20 to 30 percent faster than updates on tables where `USING HASH` was not used in creating primary and unique keys. This is due to the fact that less memory is required (because no ordered indexes are created), and that less CPU must be utilized (because fewer indexes must be read and possibly updated). However, it also means that queries that could otherwise use range scans must be satisfied by other means, which can result in slower selects.

When calculating Cluster memory requirements, you may find useful the `ndb_size.pl` utility which is available on [MySQLForge](http://forge.mysql.com/projects/view.php?id=88) [http://forge.mysql.com/projects/view.php?id=88]. This Perl script connects to a current MySQL (non-Cluster) database and creates a report on how much space that database would require if it used the `NDBCluster` storage engine. For more information, see [Section 15.9.13, “ndb_size.pl”](#).

It is especially important to keep in mind that *every MySQL Cluster table must have a primary key*. The `NDB` storage engine creates a primary key automatically if none is defined, and this primary key is created without `USING HASH`.

There is no easy way to determine exactly how much memory is being used for storage of Cluster indexes at any given time; however, warnings are written to the Cluster log when 80% of available `DataMemory` or `IndexMemory` is in use, and again when use reaches 85%, 90%, and so on.

We often see questions from users who report that, when they are trying to populate a Cluster database, the loading process terminates prematurely and an error message like this one is observed:

```
ERROR 1114: The table 'my_cluster_table' is full
```

When this occurs, the cause is very likely to be that your setup does not provide sufficient RAM for all table data and all indexes, *including the primary key required by the `NDB` storage engine and automatically created in the event that the table definition does not include the definition of a primary key*.

It is also worth noting that all data nodes should have the same amount of RAM, as no data node in a cluster can use more memory than the least amount available to any individual data node. In other words, if there are three computers hosting Cluster data nodes, with two of these having 3GB of RAM available to store Cluster data, and one having only 1GB RAM, then each data node can devote only 1GB to clustering.

- *Because MySQL Cluster uses TCP/IP, does that mean I can run it over the Internet, with one or more nodes in a remote location?*

It is very doubtful in any case that a cluster would perform reliably under such conditions, as MySQL Cluster was designed and implemented with the assumption that it would be run under conditions guaranteeing dedicated high-speed connectivity such as that found in a LAN setting using 100 Mbps or gigabit Ethernet (preferably the latter). We neither test nor warrant its performance using anything slower than this.

Also, it is extremely important to keep in mind that communications between the nodes in a MySQL Cluster are not secure; they are neither encrypted nor safeguarded by any other protective mechanism. The most secure configuration for a cluster is in a private network behind a firewall, with no direct access to any Cluster data or management nodes from outside. (For SQL nodes, you should take the same precautions as you would with any other instance of the MySQL server.)

- *Do I have to learn a new programming or query language to use Cluster?*

No. Although some specialized commands are used to manage and configure the cluster itself, only

standard (My)SQL queries and commands are required for the following operations:

- Creating, altering, and dropping tables (including Disk Data tables and related objects)
- Inserting, updating, and deleting table data
- Creating, changing, and dropping primary and unique indexes
- Configuring and managing SQL nodes (MySQL servers)

- *How do I find out what an error or warning message means when using Cluster?*

There are two ways in which this can be done:

- From within the `mysql` client, use `SHOW ERRORS` or `SHOW WARNINGS` immediately upon being notified of the error or warning condition. Errors and warnings also be displayed in MySQL Query Browser.
- From a system shell prompt, use `pererror --ndb error_code`.

- *Is MySQL Cluster transaction-safe? What isolation levels are supported?*

Yes: For tables created with the `NDB` storage engine, transactions are supported. In MySQL 5.1, Cluster supports only the `READ COMMITTED` transaction isolation level.

- *What storage engines are supported by MySQL Cluster?*

Clustering in MySQL is supported only by the `NDB` storage engine. That is, in order for a table to be shared between nodes in a cluster, it must be created using `ENGINE=NDB` (or `ENGINE=NDBCLUSTER`, which is equivalent).

It is possible to create tables using other storage engines (such as `MyISAM` or `InnoDB`) on a MySQL server being used for clustering, but these non-`NDB` tables will **not** participate in the cluster; they are local to the individual MySQL server instance on which they are created.

- *Which versions of the MySQL software support Cluster? Do I have to compile from source?*

Cluster is supported in all server binaries in the 5.1 release series for operating systems on which MySQL Cluster is available. See [Section 5.2, “mysqld — The MySQL Server”](#). You can determine whether your server has NDB support using either the `SHOW VARIABLES LIKE 'have_%'` or `SHOW ENGINES` statement.

You can also obtain NDB support by compiling MySQL from source, but it is not necessary to do so simply to use MySQL Cluster. To download the latest binary, RPM, or source distribution in the MySQL 5.1 series, visit <http://dev.mysql.com/downloads/mysql/5.1.html>.

- *In the event of a catastrophic failure — say, for instance, the whole city loses power **and** my UPS fails — would I lose all my data?*

All committed transactions are logged. Therefore, although it is possible that some data could be lost in the event of a catastrophe, this should be quite limited. Data loss can be further reduced by minimizing the number of operations per transaction. (It is not a good idea to perform large numbers of operations per transaction in any case.)

- *Is it possible to use `FULLTEXT` indexes with Cluster?*

`FULLTEXT` indexing is not currently supported by the `NDB` storage engine, or by any storage engine other than `MyISAM`. We are working to add this capability in a future release.

- *Can I run multiple nodes on a single computer?*

It is possible but not advisable. One of the chief reasons to run a cluster is to provide redundancy. To enjoy the full benefits of this redundancy, each node should reside on a separate machine. If you place multiple nodes on a single machine and that machine fails, you lose all of those nodes. Given that MySQL Cluster can be run on commodity hardware loaded with a low-cost (or even no-cost) operating system, the expense of an extra machine or two is well worth it to safeguard mission-critical data. It also worth noting that the requirements for a cluster host running a management node are minimal. This task can be accomplished with a 200 MHz Pentium CPU and sufficient RAM for the operating system plus a small amount of overhead for the `ndb_mgmd` and `ndb_mgm` processes.

It is acceptable to run multiple cluster data nodes on a single host for learning about MySQL Cluster, or for testing purposes; however, this is not supported for production use.

- *Can I add nodes to a cluster without restarting it?*

Not at present. A simple restart is all that is required for adding new MGM or SQL nodes to a Cluster. When adding data nodes the process is more complex, and requires the following steps:

1. Make a complete backup of all Cluster data.
2. Completely shut down the cluster and all cluster node processes.
3. Restart the cluster, using the `--initial` startup option.
4. Restore all cluster data from the backup.

In a future MySQL Cluster release series, we hope to implement a “hot” reconfiguration capability for MySQL Cluster to minimize (if not eliminate) the requirement for restarting the cluster when adding new nodes.

- *Are there any limitations that I should be aware of when using Cluster?*

`NDB` tables in MySQL 5.1 are subject to the following limitations:

- Temporary tables are not supported; a `CREATE TEMPORARY TABLE` statement using `ENGINE=NDB` or `ENGINE=NDBCLUSTER` fails with an error.
- The only types of user-defined partitioning supported for `NDB` tables are `KEY` and `LINEAR KEY`. (Beginning with MySQL 5.1.12, attempting to create an `NDB` table using any other partitioning type fails with an error.)
- `FULLTEXT` indexes and index prefixes are not supported. Only complete columns may be indexed.
- Spatial data types are not supported. See [Chapter 17, Spatial Extensions](#).
- Only complete rollbacks for transactions are supported. Partial rollbacks and rollbacks to savepoints are not supported.
- The maximum number of attributes allowed per table is 128, and attribute names cannot be any longer than 31 characters. For each table, the maximum combined length of the table and database names is 122 characters.
- The maximum size for a table row is 8 kilobytes, not counting `BLOB` values. There is no set limit

for the number of rows per table. Table size limits depend on a number of factors, in particular on the amount of RAM available to each data node.

- The `NDB` engine does not support foreign key constraints. As with `MyISAM` tables, these are ignored.

For additional information on Cluster limitations, see [Section 15.13, “Known Limitations of MySQL Cluster”](#).

- *How do I import an existing MySQL database into a cluster?*

You can import databases into MySQL Cluster much as you would with any other version of MySQL. Other than the limitation mentioned in the previous question, the only other special requirement is that any tables to be included in the cluster must use the `NDB` storage engine. This means that the tables must be created with `ENGINE=NDB` or `ENGINE=NDBCLUSTER`. It is also possible to convert existing tables using other storage engines to `NDB Cluster` using `ALTER TABLE`, but requires an additional workaround. See [Section 15.13, “Known Limitations of MySQL Cluster”](#), for details.

- *How do cluster nodes communicate with one another?*

Cluster nodes can communicate via any of three different protocols: TCP/IP, SHM (shared memory), and SCI (Scalable Coherent Interface). Where available, SHM is used by default between nodes residing on the same cluster host. SCI is a high-speed (1 gigabit per second and higher), high-availability protocol used in building scalable multi-processor systems; it requires special hardware and drivers. See [Section 15.12, “Using High-Speed Interconnects with MySQL Cluster”](#), for more about using SCI as a transport mechanism in MySQL Cluster.

- *What is an “arbiter”?*

If one or more nodes in a cluster fail, it is possible that not all cluster nodes will be able to “see” one another. In fact, it is possible that two sets of nodes might become isolated from one another in a network partitioning, also known as a “split brain” scenario. This type of situation is undesirable because each set of nodes tries to behave as though it is the entire cluster.

When cluster nodes go down, there are two possibilities. If more than 50% of the remaining nodes can communicate with each other, we have what is sometimes called a “majority rules” situation, and this set of nodes is considered to be the cluster. The arbiter comes into play when there is an even number of nodes: in such cases, the set of nodes to which the arbiter belongs is considered to be the cluster, and nodes not belonging to this set are shut down.

The preceding information is somewhat simplified. A more complete explanation taking into account node groups follows:

When all nodes in at least one node group are alive, network partitioning is not an issue, because no one portion of the cluster can form a functional cluster. The real problem arises when no single node group has all its nodes alive, in which case network partitioning (the “split-brain” scenario) becomes possible. Then an arbiter is required. All cluster nodes recognize the same node as the arbiter, which is normally the management server; however, it is possible to configure any of the MySQL Servers in the cluster to act as the arbiter instead. The arbiter accepts the first set of cluster nodes to contact it, and tells the remaining set to shut down. Arbiter selection is controlled by the `ArbitrationRank` configuration parameter for MySQL Server and management server nodes. (See [Section 15.4.4.4, “Defining the Management Server”](#), for details.) It should also be noted that the role of arbiter does not in and of itself impose any heavy demands upon the host so designated, and thus the arbiter host does not need to be particularly fast or to have extra memory especially for this purpose.

- *What data types are supported by MySQL Cluster?*

MySQL Cluster supports all of the usual MySQL data types, with the exception of those associated with MySQL's spatial extensions. (See [Chapter 17, *Spatial Extensions*](#).) In addition, there are some differences with regard to indexes when used with NDB tables. **Note:** MySQL Cluster Disk Data tables (that is, tables created with `TABLESPACE ... STORAGE DISK ENGINE=NDBCLUSTER`) have only fixed-width rows. This means that (for example) each Disk Data table record containing a `VARCHAR(255)` column requires space for 255 characters (as required for the character set and collation being used for the table), regardless of the actual number of characters stored therein.

See [Section 15.13, “Known Limitations of MySQL Cluster”](#), for more information about these issues.

- *How do I start and stop MySQL Cluster?*

It is necessary to start each node in the cluster separately, in the following order:

1. Start the management node with the `ndb_mgmd` command.
2. Start each data node with the `ndbd` command.
3. Start each MySQL server (SQL node) using `mysqld_safe --user=mysql &`.

Each of these commands must be run from a system shell on the machine housing the affected node. You can verify the cluster is running by starting the MGM management client `ndb_mgm` on the machine housing the MGM node.

- *What happens to cluster data when the cluster is shut down?*

The data held in memory by the cluster's data nodes is written to disk, and is reloaded in memory the next time that the cluster is started.

To shut down the cluster, enter the following command in a shell on the machine hosting the MGM node:

```
shell> ndb_mgm -e shutdown
```

This causes the `ndb_mgm`, `ndb_mgm`, and any `ndbd` processes to terminate gracefully. MySQL servers running as Cluster SQL nodes can be stopped using `mysqladmin shutdown`.

For more information, see [Section 15.7.2, “Commands in the Management Client”](#), and [Section 15.3.6, “Safe Shutdown and Restart”](#).

- *Is it helpful to have more than one management node for a cluster?*

It can be helpful as a fail-safe. Only one MGM node controls the cluster at any given time, but it is possible to configure one MGM as primary, and one or more additional management nodes to take over in the event that the primary MGM node fails.

- *Can I mix different kinds of hardware and operating systems in a Cluster?*

Yes, so long as all machines and operating systems have the same endianness (all big-endian or all little-endian). It is also possible to use different MySQL Cluster releases on different nodes. However, we recommend this be done only as part of a rolling upgrade procedure.

- *Can I run two data nodes on a single host? Two SQL nodes?*

Yes, it is possible to do this. In the case of multiple data nodes, each node must use a different data directory. If you want to run multiple SQL nodes on one machine, each instance of `mysqld` must use a different TCP/IP port. However, running more than one node of a given type per machine is not supported for production use.

- *Can I use hostnames with MySQL Cluster?*

Yes, it is possible to use DNS and DHCP for cluster hosts. However, if your application requires “five nines” availability, we recommend using fixed IP addresses. Making communication between Cluster hosts dependent on services such as DNS and DHCP introduces additional points of failure, and the fewer of these, the better.

15.16. MySQL Cluster Glossary

The following terms are useful to an understanding of MySQL Cluster or have specialized meanings when used in relation to it.

- **Cluster:**

In its generic sense, a cluster is a set of computers functioning as a unit and working together to accomplish a single task.

NDB Cluster:

This is the storage engine used in MySQL to implement data storage, retrieval, and management distributed among several computers.

MySQL Cluster:

This refers to a group of computers working together using the **NDB** storage engine to support a distributed MySQL database in a *shared-nothing architecture* using *in-memory storage*.

- **Configuration files:**

Text files containing directives and information regarding the cluster, its hosts, and its nodes. These are read by the cluster's management nodes when the cluster is started. See [Section 15.4.4, “Configuration File”](#), for details.

- **Backup:**

A complete copy of all cluster data, transactions and logs, saved to disk or other long-term storage.

- **Restore:**

Returning the cluster to a previous state, as stored in a backup.

- **Checkpoint:**

Generally speaking, when data is saved to disk, it is said that a checkpoint has been reached. More specific to Cluster, it is a point in time where all committed transactions are stored on disk. With regard to the **NDB** storage engine, there are two types of checkpoints which work together to ensure that a consistent view of the cluster's data is maintained:

- **Local Checkpoint (LCP):**

This is a checkpoint that is specific to a single node; however, LCP's take place for all nodes in

the cluster more or less concurrently. An LCP involves saving all of a node's data to disk, and so usually occurs every few minutes. The precise interval varies, and depends upon the amount of data stored by the node, the level of cluster activity, and other factors.

- **Global Checkpoint (GCP):**

A GCP occurs every few seconds, when transactions for all nodes are synchronized and the redo-log is flushed to disk.

- **Cluster host:**

A computer making up part of a MySQL Cluster. A cluster has both a *physical* structure and a *logical* structure. Physically, the cluster consists of a number of computers, known as *cluster hosts* (or more simply as *hosts*). See also **Node** and **Node group** below.

- **Node:**

This refers to a logical or functional unit of MySQL Cluster, and is sometimes also referred to as a *cluster node*. In the context of MySQL Cluster, we use the term “node” to indicate a *process* rather than a physical component of the cluster. There are three node types required to implement a working MySQL Cluster:

- **Management (MGM) nodes:**

Manages the other nodes within the MySQL Cluster. It provides configuration data to the other nodes; starts and stops nodes; handles network partitioning; creates backups and restores from them, and so forth.

- **SQL (MySQL server) nodes:**

Instances of MySQL Server which serve as front ends to data kept in the cluster's **data nodes**. Clients desiring to store, retrieve, or update data can access an SQL node just as they would any other MySQL Server, employing the usual authentication methods and API's; the underlying distribution of data between node groups is transparent to users and applications. SQL nodes access the cluster's databases as a whole without regard to the data's distribution across different data nodes or cluster hosts.

- **Data nodes:**

These nodes store the actual data. Table data fragments are stored in a set of node groups; each node group stores a different subset of the table data. Each of the nodes making up a node group stores a replica of the fragment for which that node group is responsible. Currently, a single cluster can support up to 48 data nodes total.

It is possible for more than one node to co-exist on a single machine. (In fact, it is even possible to set up a complete cluster on one machine, although one would almost certainly *not* want to do this in a production environment.) It may be helpful to remember that, when working with MySQL Cluster, the term *host* refers to a physical component of the cluster whereas a *node* is a logical or functional component (that is, a process).

Note Regarding Terms: In older versions of the MySQL Cluster documentation, data nodes were sometimes referred to as “database nodes”. The term “storage nodes” has also been used. In addition, SQL nodes were sometimes known as “client nodes”. This older terminology has been deprecated to minimize confusion, and for this reason should be avoided. They are also often referred to as “API nodes” — an SQL node is actually an API node that provides an SQL interface to the cluster.

- **Node group:**

A set of data nodes. All data nodes in a node group contain the same data (fragments), and all nodes in a single group should reside on different hosts. It is possible to control which nodes belong to which node groups.

For more information, see [Section 15.2.1, “MySQL Cluster Nodes, Node Groups, Replicas, and Partitions”](#).

- **Node failure:**

MySQL Cluster is not solely dependent upon the functioning of any single node making up the cluster; the cluster can continue to run if one or more nodes fail. The precise number of node failures that a given cluster can tolerate depends upon the number of nodes and the cluster's configuration.

- **Node restart:**

The process of restarting a failed cluster node.

- **Initial node restart:**

The process of starting a cluster node with its filesystem removed. This is sometimes used in the course of software upgrades and in other special circumstances.

- **System crash (or system failure):**

This can occur when so many cluster nodes have failed that the cluster's state can no longer be guaranteed.

- **System restart:**

The process of restarting the cluster and reinitializing its state from disk logs and checkpoints. This is required after either a planned or an unplanned shutdown of the cluster.

- **Fragment:**

A portion of a database table; in the [NDB](#) storage engine, a table is broken up into and stored as a number of fragments. A fragment is sometimes also called a “partition”; however, “fragment” is the preferred term. Tables are fragmented in MySQL Cluster in order to facilitate load balancing between machines and nodes.

- **Replica:**

Under the [NDB](#) storage engine, each table fragment has number of replicas stored on other data nodes in order to provide redundancy. Currently, there may be up four replicas per fragment.

- **Transporter:**

A protocol providing data transfer between nodes. MySQL Cluster currently supports four different types of transporter connections:

- **TCP/IP**

This is, of course, the familiar network protocol that underlies HTTP, FTP (and so on) on the Internet. TCP/IP can be used for both local and remote connections.

- **SCI**

Scalable Coherent Interface is a high-speed protocol used in building multiprocessor systems and parallel-processing applications. Use of SCI with MySQL Cluster requires specialized hard-

ware, as discussed in [Section 15.12.1, “Configuring MySQL Cluster to use SCI Sockets”](#). For a basic introduction to SCI, see [this essay at dolphinics.com](http://www.dolphinics.com/corporate/scitech.html) [<http://www.dolphinics.com/corporate/scitech.html>].

- **SHM**

Unix-style **shared memory** segments. Where supported, SHM is used automatically to connect nodes running on the same host. The [Unix man page for `shmop\(2\)`](#) [<http://www.scit.wlv.ac.uk/cgi-bin/mansec?2+shmop>] is a good place to begin obtaining additional information about this topic.

Note: The cluster transporter is internal to the cluster. Applications using MySQL Cluster communicate with SQL nodes just as they do with any other version of MySQL Server (via TCP/IP, or through the use of Unix socket files or Windows named pipes). Queries can be sent and results retrieved using the standard MySQL client APIs.

- **NDB:**

This stands for **Network Database**, and refers to the storage engine used to enable MySQL Cluster. The **NDB** storage engine supports all the usual MySQL data types and SQL statements, and is ACID-compliant. This engine also provides full support for transactions (commits and rollbacks).

- **shared-nothing architecture:**

The ideal architecture for a MySQL Cluster. In a true shared-nothing setup, each node runs on a separate host. The advantage such an arrangement is that there no single host or node can act as single point of failure or as a performance bottle neck for the system as a whole.

- **In-memory storage:**

All data stored in each data node is kept in memory on the node's host computer. For each data node in the cluster, you must have available an amount of RAM equal to the size of the database times the number of replicas, divided by the number of data nodes. Thus, if the database takes up 1GB of memory, and you want to set up the cluster with four replicas and eight data nodes, a minimum of 500MB memory will be required per node. Note that this is in addition to any requirements for the operating system and any other applications that might be running on the host.

In MySQL 5.1, it is also possible to create *Disk Data* tables where non-indexed columns are stored on disk, thus reducing the memory footprint required by the cluster. Note that indexes and indexed column data are still stored in RAM. See [Section 15.11, “MySQL Cluster Disk Data Storage”](#).

- **Table:**

As is usual in the context of a relational database, the term “table” denotes a set of identically structured records. In MySQL Cluster, a database table is stored in a data node as a set of fragments, each of which is replicated on additional data nodes. The set of data nodes replicating the same fragment or set of fragments is referred to as a *node group*.

- **Cluster programs:**

These are command-line programs used in running, configuring, and administering MySQL Cluster. They include both server daemons:

- **`ndbd`:**

The data node daemon (runs a data node process)

- **`ndb_mgmd`:**

The management server daemon (runs a management server process)

and client programs:

- `ndb_mgm`:

The management client (provides an interface for executing management commands)

- `ndb_waiter`:

Used to verify status of all nodes in a cluster

- `ndb_restore`:

Restores cluster data from backup

For more about these programs and their uses, see [Section 15.6, “Process Management in MySQL Cluster”](#).

- **Event log:**

MySQL Cluster logs events by category (startup, shutdown, errors, checkpoints, and so on), priority, and severity. A complete listing of all reportable events may be found in [Section 15.7.3, “Event Reports Generated in MySQL Cluster”](#). Event logs are of two types:

- **Cluster log:**

Keeps a record of all desired reportable events for the cluster as a whole.

- **Node log:**

A separate log which is also kept for each individual node.

Under normal circumstances, it is necessary and sufficient to keep and examine only the cluster log. The node logs need be consulted only for application development and debugging purposes.

Chapter 16. Partitioning

This chapter discusses *user-defined partitioning*, as implemented in MySQL 5.1.

An introduction to partitioning and partitioning concepts may be found in [Section 16.1, “Overview of Partitioning in MySQL”](#).

MySQL supports several types of partitioning, which are discussed in [Section 16.2, “Partition Types”](#), as well as subpartitioning, which is described in [Section 16.2.5, “Subpartitioning”](#).

Methods of adding, removing, and altering partitions in existing partitioned tables are covered in [Section 16.3, “Partition Management”](#).

Table maintenance commands for use with partitioned tables are discussed in [Section 16.3.3, “Maintenance of Partitions”](#).

Important: Partitioned tables created with MySQL versions prior to 5.1.6 cannot be read by a 5.1.6 or later MySQL Server. In addition, the `INFORMATION_SCHEMA.TABLES` table cannot be used if such tables are present on a 5.1.6 server. Beginning with MySQL 5.1.7, a suitable warning message is generated instead, to alert the user that incompatible partitioned tables have been found by the server.

Important: If you are using partitioned tables which were created in MySQL 5.1.5 or earlier, be sure to see [Section D.1.7, “Changes in release 5.1.6 \(01 February 2006\)”](#) for more information and suggested workarounds *before* upgrading to MySQL 5.1.6 or later.

The partitioning implementation in MySQL 5.1 is still undergoing development. For known issues with MySQL partitioning, see [Section 16.5, “Restrictions and Limitations on Partitioning”](#), where we have noted these.

You may also find the following resources to be useful when working with partitioned tables.

Additional Resources:

- [MySQL Partitioning Forum](http://forums.mysql.com/list.php?106) [http://forums.mysql.com/list.php?106]

This is the official discussion forum for those interested in or experimenting with MySQL Partitioning technology. It features announcements and updates from MySQL developers and others. It is monitored by members of the Partitioning Development and Documentation Teams.

- [Mikael Ronström's Blog](http://mikaelronstrom.blogspot.com/) [http://mikaelronstrom.blogspot.com/]

MySQL Partitioning Architect and Lead Developer Mikael Ronström frequently posts articles here concerning his work with MySQL Partitioning and MySQL Cluster.

- [PlanetMySQL](http://www.planetmysql.org/) [http://www.planetmysql.org/]

A MySQL news site featuring MySQL-related blogs, which should be of interest to anyone using my MySQL. We encourage you to check here for links to blogs kept by those working with MySQL Partitioning, or to have your own blog added to those covered.

MySQL 5.1 binaries are now available from <http://dev.mysql.com/downloads/mysql/5.1.html>. However, for the latest partitioning bugfixes and feature additions, you can obtain the source from our BitKeeper repository. To enable partitioning, you need to compile the server using the `--with-partition` option. For more information about building MySQL, see [Section 2.9, “MySQL Installation Using a Source Distribution”](#). If you have problems compiling a partitioning-enabled MySQL 5.1 build, check the [MySQL Partitioning Forum](http://forums.mysql.com/list.php?106) [http://forums.mysql.com/list.php?106] and ask for assistance there if

you don't find a solution to your problem already posted.

16.1. Overview of Partitioning in MySQL

This section provides a conceptual overview of partitioning in MySQL 5.1.

For information on partitioning restrictions and feature limitations, see [Section 16.5, “Restrictions and Limitations on Partitioning”](#).

The SQL standard does not provide much in the way of guidance regarding the physical aspects of data storage. The SQL language itself is intended to work independently of any data structures or media underlying the schemas, tables, rows, or columns with which it works. Nonetheless, most advanced database management systems have evolved some means of determining the physical location to be used for storing specific pieces of data in terms of the filesystem, hardware or even both. In MySQL, the `InnoDB` storage engine has long supported the notion of a tablespace, and the MySQL Server, even prior to the introduction of partitioning, could be configured to employ different physical directories for storing different databases (see [Section 7.6.1, “Using Symbolic Links”](#), for an explanation of how this is done).

Partitioning takes this notion a step further, by allowing you to distribute portions of individual tables across a filesystem according to rules which you can set largely as needed. In effect, different portions of a table are stored as separate tables in different locations. The user-selected rule by which the division of data is accomplished is known as a *partitioning function*, which in MySQL can be the modulus, simple matching against a set of ranges or value lists, an internal hashing function, or a linear hashing function. The function is selected according to the partitioning type specified by the user, and takes as its parameter the value of a user-supplied expression. This expression can be either an integer column value, or a function acting on one or more column values and returning an integer. The value of this expression is passed to the partitioning function, which returns an integer value representing the number of the partition in which that particular record should be stored. This function must be non-constant and non-random. It may not contain any queries, but may use virtually any SQL expression that is valid in MySQL, so long as that expression returns a positive integer less than `MAXVALUE` (the greatest possible positive integer). Examples of partitioning functions can be found in the discussions of partitioning types later in this chapter (see [Section 16.2, “Partition Types”](#)), as well as in the partitioning syntax descriptions given in [Section 13.1.7, “CREATE TABLE Syntax”](#).

This is known as *horizontal partitioning* — that is, different rows of a table may be assigned to different physical partitions. MySQL 5.1 does not support *vertical partitioning*, in which different columns of a table are assigned to different physical partitions. There are not at this time any plans to introduce vertical partitioning into MySQL 5.1.

Partitioning support is included in the `-max` releases of MySQL 5.1 (that is, the 5.1 `-max` binaries will be built with `--with-partition`). If the MySQL binary is built with partitioning support, nothing further needs to be done in order to enable it (for example, no special entries are required in your `my.cnf` file). You can determine whether your MySQL server supports partitioning by means of a `SHOW VARIABLES` command such as this one:

```
mysql> SHOW VARIABLES LIKE '%partition%';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| have_partitioning | YES |
+-----+-----+
1 row in set (0.00 sec)
```

If you do not see the `have_partitioning` variable with the value `YES` listed as shown above in the output of an appropriate `SHOW VARIABLES`, then your version of MySQL does not support partitioning.

Prior to MySQL 5.1.6, this variable was named `have_partition_engine`. ([Bug#16718](#))

[<http://bugs.mysql.com/16718>]

For creating partitioned tables, you can use most storage engines that are supported by your MySQL server; the MySQL partitioning engine runs in a separate layer and can interact with any of these. In MySQL 5.1, all partitions of the same partitioned table must use the same storage engine; for example, you cannot use [MyISAM](#) for one partition and [InnoDB](#) for another. However, there is nothing preventing you from using different storage engines for different partitioned tables on the same MySQL server or even in the same database.

Note: MySQL partitioning cannot be used with the [MERGE](#) or [CSV](#) storage engines. Prior to MySQL 5.1.6, it was also not feasible to create a partitioned table using the [BLACKHOLE](#) storage engine. ([Bug#14524](#) [<http://bugs.mysql.com/14524>]). Partitioning by [KEY](#) is supported for use with the [NDB-Cluster](#) storage engine, but other types of user-defined partitioning are not supported for Cluster tables in MySQL 5.1.

To employ a particular storage engine for a partitioned table, it is necessary only to use the [\[STORAGE \] ENGINE](#) option just as you would for a non-partitioned table. However, you should keep in mind that [\[STORAGE \] ENGINE](#) (and other table options) need to be listed *before* any partitioning options are used in a [CREATE TABLE](#) statement. This example shows how to create a table that is partitioned by hash into 6 partitions and which uses the [InnoDB](#) storage engine:

```
CREATE TABLE ti (id INT, amount DECIMAL(7,2), tr_date DATE)
ENGINE=INNODB
PARTITION BY HASH( MONTH(tr_date) )
PARTITIONS 6;
```

(Note that each [PARTITION](#) clause can include a [\[STORAGE \] ENGINE](#) option, but in MySQL 5.1 this has no effect.)

Note: Partitioning applies to all data and indexes of a table; you cannot partition only the data and not the indexes, or *vice versa*, nor can you partition only a portion of the table.

Data and indexes for each partition can be assigned to a specific directory using the [DATA DIRECTORY](#) and [INDEX DIRECTORY](#) options for the [PARTITION](#) clause of the [CREATE TABLE](#) statement used to create the partitioned table. In addition, [MAX_ROWS](#) and [MIN_ROWS](#) can be used to determine the maximum and minimum numbers of rows, respectively, that can be stored in each partition. See [Section 16.3, “Partition Management”](#), for more information on these options.

Some of the advantages of partitioning include:

- Being able to store more data in one table than can be held on a single disk or filesystem partition.
- Data that loses its usefulness can often be easily removed from the table by dropping the partition containing only that data. Conversely, the process of adding new data can in some cases be greatly facilitated by adding a new partition specifically for that data.
- Some queries can be greatly optimized in virtue of the fact that data satisfying a given [WHERE](#) clause can be stored only on one or more partitions, thereby excluding any remaining partitions from the search. Because partitions can be altered after a partitioned table has been created, you can reorganize your data to enhance frequent queries that may not have been so when the partitioning scheme was first set up. This capability, sometimes referred to as *partition pruning*, was implemented in MySQL 5.1.6. For additional information, see [Section 16.4, “Partition Pruning”](#).

Other benefits usually associated with partitioning include those in the following list. These features are not currently implemented in MySQL Partitioning, but are high on our list of priorities.

- Queries involving aggregate functions such as [SUM\(\)](#) and [COUNT\(\)](#) can easily be parallelized. A

simple example of such a query might be `SELECT salesperson_id, COUNT(orders) as order_total FROM sales GROUP BY salesperson_id;`. By “parallelized,” we mean that the query can be run simultaneously on each partition, and the final result obtained merely by summing the results obtained for all partitions.

- Achieving greater query throughput in virtue of spreading data seeks over multiple disks.

Be sure to check this section and chapter frequently for updates as Partitioning development continues.

16.2. Partition Types

This section discusses the types of partitioning which are available in MySQL 5.1. These include:

- **RANGE partitioning:** Assigns rows to partitions based on column values falling within a given range. See [Section 16.2.1, “RANGE Partitioning”](#).
- **LIST partitioning:** Similar to partitioning by range, except that the partition is selected based on columns matching one of a set of discrete values. See [Section 16.2.2, “LIST Partitioning”](#).
- **HASH partitioning:** A partition is selected based on the value returned by a user-defined expression that operates on column values in rows to be inserted into the table. The function may consist of any expression valid in MySQL that yields a non-negative integer value. See [Section 16.2.3, “HASH Partitioning”](#).
- **KEY partitioning:** Similar to partitioning by hash, except that only one or more columns to be evaluated are supplied, and the MySQL server provides its own hashing function. These columns can contain other than integer values, since the hashing function supplied by MySQL guarantees an integer result regardless of the column data type. See [Section 16.2.4, “KEY Partitioning”](#).

A very common use of database partitioning is to segregate data by date. Some database systems support explicit date partitioning, which MySQL does not implement in 5.1. However, it is not difficult in MySQL to create partitioning schemes based on `DATE`, `TIME`, or `DATETIME` columns, or based on expressions making use of such columns.

When partitioning by `KEY` or `LINEAR KEY`, you can use a `DATE`, `TIME`, or `DATETIME` column as the partitioning column without performing any modification of the column value. For example, this table creation statement is perfectly valid in MySQL:

```
CREATE TABLE members (
  firstname VARCHAR(25) NOT NULL,
  lastname VARCHAR(25) NOT NULL,
  username VARCHAR(16) NOT NULL,
  email VARCHAR(35),
  joined DATE NOT NULL
)
PARTITION BY KEY(joined)
PARTITIONS 6;
```

MySQL's other partitioning types, however, require a partitioning expression that yields an integer value or `NULL`. If you wish to use date-based partitioning by `RANGE`, `LIST`, `HASH`, or `LINEAR HASH`, you can simply employ a function that operates on a `DATE`, `TIME`, or `DATETIME` column and returns such a value, as shown here:

```
CREATE TABLE members (
  firstname VARCHAR(25) NOT NULL,
  lastname VARCHAR(25) NOT NULL,
  username VARCHAR(16) NOT NULL,
  email VARCHAR(35),
  joined DATE NOT NULL
```

```

)
PARTITION BY RANGE( YEAR(joined) ) (
  PARTITION p0 VALUES LESS THAN (1960),
  PARTITION p1 VALUES LESS THAN (1970),
  PARTITION p2 VALUES LESS THAN (1980),
  PARTITION p3 VALUES LESS THAN (1990),
  PARTITION p4 VALUES LESS THAN MAXVALUE
);

```

Additional examples of partitioning using dates may be found here:

- [Section 16.2.1, “RANGE Partitioning”](#)
- [Section 16.2.3, “HASH Partitioning”](#)
- [Section 16.2.3.1, “LINEAR HASH Partitioning”](#)

For more complex examples of date-based partitioning, see:

- [Section 16.4, “Partition Pruning”](#)
- [Section 16.2.5, “Subpartitioning”](#)

MySQL partitioning is optimised for use with the `TO_DAYS()` and `YEAR()` functions. However, you can use other date and time functions that return an integer or `NULL`, such as `WEEKDAY()`, `DAY-OFYEAR()`, or `MONTH()`. See [Section 12.5, “Date and Time Functions”](#), for more information about such functions.

It is important to remember — regardless of the type of partitioning that you use — that partitions are always numbered automatically and in sequence when created, starting with 0. When a new row is inserted into a partitioned table, it is these partition numbers that are used in identifying the correct partition. For example, if your table uses 4 partitions, these partitions are numbered 0, 1, 2, and 3. For the `RANGE` and `LIST` partitioning types, it is necessary to ensure that there is a partition defined for each partition number. For `HASH` partitioning, the user function employed must return an integer value greater than 0. For `KEY` partitioning, this issue is taken care of automatically by the hashing function which the MySQL server employs internally.

Names of partitions generally follow the rules governing other MySQL identifiers, such as those for tables and databases. However, you should note that partition names are not case-sensitive. For example, the following `CREATE TABLE` statement fails as shown:

```

mysql> CREATE TABLE t2 (val INT)
-> PARTITION BY LIST(val)(
->     PARTITION mypart VALUES IN (1,3,5),
->     PARTITION MyPart VALUES IN (2,4,6)
-> );
ERROR 1488 (HY000): Duplicate partition name mypart

```

Failure occurs because MySQL sees no difference between the partition names `mypart` and `MyPart`.

When you specify the number of partitions for the table, this must be expressed as a positive, non-zero integer literal with no leading zeroes, and may not be an expression such as `0.8E+01` or `6-2`, even if it evaluates as an integer. (Beginning with MySQL 5.1.12, decimal fractions are no longer truncated, but instead are disallowed entirely.)

In the sections that follow, we do not necessarily provide all possible forms for the syntax that can be used for creating each partition type; this information may be found in [Section 13.1.7, “CREATE TABLE Syntax”](#).

16.2.1. RANGE Partitioning

A table that is partitioned by range is partitioned in such a way that each partition contains rows for which the partitioning expression value lies within a given range. Ranges should be contiguous but not overlapping, and are defined using the `VALUES LESS THAN` operator. For the next few examples, suppose that you are creating a table such as the following to hold personnel records for a chain of 20 video stores, numbered 1 through 20:

```
CREATE TABLE employees (
  id INT NOT NULL,
  fname VARCHAR(30),
  lname VARCHAR(30),
  hired DATE NOT NULL DEFAULT '1970-01-01',
  separated DATE NOT NULL DEFAULT '9999-12-31',
  job_code INT NOT NULL,
  store_id INT NOT NULL
);
```

This table can be partitioned by range in a number of ways, depending on your needs. One way would be to use the `store_id` column. For instance, you might decide to partition the table 4 ways by adding a `PARTITION BY RANGE` clause as shown here:

```
CREATE TABLE employees (
  id INT NOT NULL,
  fname VARCHAR(30),
  lname VARCHAR(30),
  hired DATE NOT NULL DEFAULT '1970-01-01',
  separated DATE NOT NULL DEFAULT '9999-12-31',
  job_code INT NOT NULL,
  store_id INT NOT NULL
)
PARTITION BY RANGE (store_id) (
  PARTITION p0 VALUES LESS THAN (6),
  PARTITION p1 VALUES LESS THAN (11),
  PARTITION p2 VALUES LESS THAN (16),
  PARTITION p3 VALUES LESS THAN (21)
);
```

In this partitioning scheme, all rows corresponding to employees working at stores 1 through 5 are stored in partition `p0`, to those employed at stores 6 through 10 are stored in partition `p1`, and so on. Note that each partition is defined in order, from lowest to highest. This is a requirement of the `PARTITION BY RANGE` syntax; you can think of it as being analogous to a `switch ... case` in C or Java in this regard.

It is easy to determine that a new row containing the data `(72, 'Michael', 'Widenius', '1998-06-25', NULL, 13)` is inserted into partition `p2`, but what happens when your chain adds a 21st store? Under this scheme, there is no rule that covers a row whose `store_id` is greater than 20, so an error results because the server does not know where to place it. You can keep this from occurring by using a “catchall” `VALUES LESS THAN` clause in the `CREATE TABLE` statement that provides for all values greater than highest value explicitly named:

```
CREATE TABLE employees (
  id INT NOT NULL,
  fname VARCHAR(30),
  lname VARCHAR(30),
  hired DATE NOT NULL DEFAULT '1970-01-01',
  separated DATE NOT NULL DEFAULT '9999-12-31',
  job_code INT NOT NULL,
  store_id INT NOT NULL
)
PARTITION BY RANGE (store_id) (
  PARTITION p0 VALUES LESS THAN (6),
  PARTITION p1 VALUES LESS THAN (11),
  PARTITION p2 VALUES LESS THAN (16),
  PARTITION p3 VALUES LESS THAN MAXVALUE
);
```

`MAXVALUE` represents the greatest possible integer value. Now, any rows whose `store_id` column value is greater than or equal to 16 (the highest value defined) are stored in partition `p3`. At some point in the future — when the number of stores has increased to 25, 30, or more — you can use an `ALTER TABLE` statement to add new partitions for stores 21-25, 26-30, and so on (see [Section 16.3, “Partition Management”](#), for details of how to do this).

In much the same fashion, you could partition the table based on employee job codes — that is, based on ranges of `job_code` column values. For example — assuming that two-digit job codes are used for regular (in-store) workers, three-digit codes are used for office and support personnel, and four-digit codes are used for management positions — you could create the partitioned table using the following:

```
CREATE TABLE employees (
  id INT NOT NULL,
  fname VARCHAR(30),
  lname VARCHAR(30),
  hired DATE NOT NULL DEFAULT '1970-01-01',
  separated DATE NOT NULL DEFAULT '9999-12-31',
  job_code INT NOT NULL,
  store_id INT NOT NULL
)
PARTITION BY RANGE (job_code) (
  PARTITION p0 VALUES LESS THAN (100),
  PARTITION p1 VALUES LESS THAN (1000),
  PARTITION p2 VALUES LESS THAN (10000)
);
```

In this instance, all rows relating to in-store workers would be stored in partition `p0`, those relating to office and support staff in `p1`, and those relating to managers in partition `p2`.

It is also possible to use an expression in `VALUES LESS THAN` clauses. However, MySQL must be able to evaluate the expression's return value as part of a `LESS THAN (<)` comparison.

Rather than splitting up the table data according to store number, you can use an expression based on one of the two `DATE` columns instead. For example, let us suppose that you wish to partition based on the year that each employee left the company; that is, the value of `YEAR(separated)`. An example of a `CREATE TABLE` statement that implements such a partitioning scheme is shown here:

```
CREATE TABLE employees (
  id INT NOT NULL,
  fname VARCHAR(30),
  lname VARCHAR(30),
  hired DATE NOT NULL DEFAULT '1970-01-01',
  separated DATE NOT NULL DEFAULT '9999-12-31',
  job_code INT,
  store_id INT
)
PARTITION BY RANGE ( YEAR(separated) ) (
  PARTITION p0 VALUES LESS THAN (1991),
  PARTITION p1 VALUES LESS THAN (1996),
  PARTITION p2 VALUES LESS THAN (2001),
  PARTITION p3 VALUES LESS THAN MAXVALUE
);
```

In this scheme, for all employees who left before 1991, the rows are stored in partition `p0`; for those who left in the years 1991 through 1995, in `p1`; for those who left in the years 1996 through 2000, in `p2`; and for any workers who left after the year 2000, in `p3`.

Range partitioning is particularly useful when:

- You want or need to delete “old” data. If you are using the partitioning scheme shown immediately above, you can simply use `ALTER TABLE employees DROP PARTITION p0`; to delete all rows relating to employees who stopped working for the firm prior to 1991. (See [Section 13.1.2, “ALTER TABLE Syntax”](#), and [Section 16.3, “Partition Management”](#), for more information.) For a table with a great many rows, this can be much more efficient than running a `DELETE` query such as

```
DELETE FROM employees WHERE YEAR(separated) <= 1990;
```

- You want to use a column containing date or time values, or containing values arising from some other series.
- You frequently run queries that depend directly on the column used for partitioning the table. For example, when executing a query such as `SELECT COUNT(*) FROM employees WHERE YEAR(separated) = 2000 GROUP BY store_id;`, MySQL can quickly determine that only partition `p2` needs to be scanned because the remaining partitions cannot contain any records satisfying the `WHERE` clause. See [Section 16.4, “Partition Pruning”](#), for more information about how this is accomplished.

16.2.2. LIST Partitioning

List partitioning in MySQL is similar to range partitioning in many ways. As in partitioning by [RANGE](#), each partition must be explicitly defined. The chief difference is that, in list partitioning, each partition is defined and selected based on the membership of a column value in one of a set of value lists, rather than in one of a set of contiguous ranges of values. This is done by using `PARTITION BY LIST(expr)` where `expr` is a column value or an expression based on a column value and returning an integer value, and then defining each partition by means of a `VALUES IN (value_list)`, where `value_list` is a comma-separated list of integers.

Note: In MySQL 5.1, it is possible to match against only a list of integers (and possibly `NULL` — see [Section 16.2.6, “How MySQL Partitioning Handles NULL Values”](#)) when partitioning by `LIST`.

Unlike the case with partitions defined by range, list partitions do not need to be declared in any particular order. For more detailed syntactical information, see [Section 13.1.7, “CREATE TABLE Syntax”](#).

For the examples that follow, we assume that the basic definition of the table to be partitioned is provided by the `CREATE TABLE` statement shown here:

```
CREATE TABLE employees (
  id INT NOT NULL,
  fname VARCHAR(30),
  lname VARCHAR(30),
  hired DATE NOT NULL DEFAULT '1970-01-01',
  separated DATE NOT NULL DEFAULT '9999-12-31',
  job_code INT,
  store_id INT
);
```

(This is the same table used as a basis for the examples in [Section 16.2.1, “RANGE Partitioning”](#).)

Suppose that there are 20 video stores distributed among 4 franchises as shown in the following table:

Region	Store ID Numbers
North	3, 5, 6, 9, 17
East	1, 2, 10, 11, 19, 20
West	4, 12, 13, 14, 18
Central	7, 8, 15, 16

To partition this table in such a way that rows for stores belonging to the same region are stored in the same partition, you could use the `CREATE TABLE` statement shown here:

```
CREATE TABLE employees (
  id INT NOT NULL,
  fname VARCHAR(30),
```

```

lname VARCHAR(30),
hired DATE NOT NULL DEFAULT '1970-01-01',
separated DATE NOT NULL DEFAULT '9999-12-31',
job_code INT,
store_id INT
)
PARTITION BY LIST(store_id) (
PARTITION pNorth VALUES IN (3,5,6,9,17),
PARTITION pEast VALUES IN (1,2,10,11,19,20),
PARTITION pWest VALUES IN (4,12,13,14,18),
PARTITION pCentral VALUES IN (7,8,15,16)
);

```

This makes it easy to add or drop employee records relating to specific regions to or from the table. For instance, suppose that all stores in the West region are sold to another company. All rows relating to employees working at stores in that region can be deleted with the query `ALTER TABLE employees DROP PARTITION pWest;`, which can be executed much more efficiently than the equivalent `DELETE FROM employees WHERE store_id IN (4,12,13,14,18);`.

As with `RANGE` and `HASH` partitioning, if you wish to partition a table by a column whose value is not an integer or `NULL`, you must employ a partitioning expression based on that column which returns such a value. For example, suppose that the table containing employee data is defined as shown here:

```

CREATE TABLE employees (
id INT NOT NULL,
fname VARCHAR(30),
lname VARCHAR(30),
hired DATE NOT NULL DEFAULT '1970-01-01',
separated DATE NOT NULL DEFAULT '9999-12-31',
job_code CHAR(1),
store_id INT
);

```

In this version of the `employees` table, the job code is a letter rather than a number. Each letter corresponds to a specific job, and we wish to partition the table in such a way that records for employees having similar jobs or working in the same department are grouped into the same partition, according to the following scheme:

Job Category or Department	Job Codes
Management	D, M, O, P
Sales	B, L, S
Technical	A, E, G, I, T
Clerical	K, N, Y
Support	C, F, J, R, V
Unassigned	“Empty”

Since we cannot use character values in value-lists, we need to convert these into integers or `NULL`s. For this purpose, we can use the `ASCII()` function on the column value. In addition — due to the use of different applications at different times and locations — these codes may be either uppercase or lowercase, and the “empty” value representing “currently unassigned” may actually be a `NULL`, an empty string, or a space character. A partitioned table that implements this scheme is shown here:

```

CREATE TABLE employees (
id INT NOT NULL,
fname VARCHAR(30),
lname VARCHAR(30),
hired DATE NOT NULL DEFAULT '1970-01-01',
separated DATE NOT NULL DEFAULT '9999-12-31',
job_code CHAR(1),
store_id INT
)
PARTITION BY LIST(ASCII( UCASE(job_code) )) (

```

```

PARTITION management VALUES IN(68, 77, 79, 80),
PARTITION sales VALUES IN(66, 76, 83),
PARTITION technical VALUES IN(65, 69, 71, 73, 84),
PARTITION clerical VALUES IN(75, 78, 89),
PARTITION support VALUES IN(67, 70, 74, 82, 86),
PARTITION unassigned VALUES IN(NULL, 0, 32)
);

```

Since expressions are not permitted in partition value lists, you must list the ASCII codes for the letters that are to be matched. Note that `ASCII(NULL)` returns `NULL`.

Important: If you try to insert a row such that the column value (or the partitioning expression's return value) is not found in any of the partitioning value lists, the `INSERT` query will fail with an error. For example, given the `LIST` partitioning scheme just outlined, this query will fail:

```

INSERT INTO employees VALUES
(224, 'Linus', 'Torvalds', '2002-05-01', '2004-10-12', 'Q', 21);

```

Failure occurs because 81 (the ASCII code for the uppercase letter 'Q' is not found in any of the value lists used to define any of the partitions. *There is no “catch-all” definition for list partitions analogous to `VALUES LESS THAN(MAXVALUE)` which accommodates values not found in any of the value lists. In other words, any value which is to be matched must be found in one of the value lists.*

As with `RANGE` partitioning, it is possible to combine `LIST` partitioning with partitioning by hash or key to produce a composite partitioning (subpartitioning). See [Section 16.2.5, “Subpartitioning”](#).

16.2.3. HASH Partitioning

Partitioning by `HASH` is used primarily to ensure an even distribution of data among a predetermined number of partitions. With range or list partitioning, you must specify explicitly into which partition a given column value or set of column values is to be stored; with hash partitioning, MySQL takes care of this for you, and you need only specify a column value or expression based on a column value to be hashed and the number of partitions into which the partitioned table is to be divided.

To partition a table using `HASH` partitioning, it is necessary to append to the `CREATE TABLE` statement a `PARTITION BY HASH (expr)` clause, where `expr` is an expression that returns an integer. This can simply be the name of a column whose type is one of MySQL's integer types. In addition, you will most likely want to follow this with a `PARTITIONS num` clause, where `num` is a non-negative integer representing the number of partitions into which the table is to be divided.

For example, the following statement creates a table that uses hashing on the `store_id` column and is divided into 4 partitions:

```

CREATE TABLE employees (
  id INT NOT NULL,
  fname VARCHAR(30),
  lname VARCHAR(30),
  hired DATE NOT NULL DEFAULT '1970-01-01',
  separated DATE NOT NULL DEFAULT '9999-12-31',
  job_code INT,
  store_id INT
)
PARTITION BY HASH(store_id)
PARTITIONS 4;

```

If you do not include a `PARTITIONS` clause, the number of partitions defaults to 1.

Using the `PARTITIONS` keyword without a number following it results in a syntax error.

You can also use an SQL expression that returns an integer for `expr`. For instance, you might want to partition based on the year in which an employee was hired. This can be done as shown here:

```
CREATE TABLE employees (
  id INT NOT NULL,
  fname VARCHAR(30),
  lname VARCHAR(30),
  hired DATE NOT NULL DEFAULT '1970-01-01',
  separated DATE NOT NULL DEFAULT '9999-12-31',
  job_code INT,
  store_id INT
)
PARTITION BY HASH( YEAR(hired) )
PARTITIONS 4;
```

You may use any function or other expression for *expr* that is valid in MySQL, so long as it returns a non-constant, non-random integer value. (In other words, it should be varying but deterministic.)

However, you should keep in mind that this expression is evaluated each time a row is inserted or updated (or possibly deleted); this means that very complex expressions may give rise to performance issues, particularly when performing operations (such as batch inserts) that affect a great many rows at one time.

The most efficient hashing function is one which operates upon a single table column and whose value increases or decreases consistently with the column value, as this allows for “pruning” on ranges of partitions. That is, the more closely that the expression varies with the value of the column on which it is based, the more efficiently MySQL can use the expression for hash partitioning.

For example, where *date_col* is a column of type `DATE`, then the expression `TO_DAYS(date_col)` is said to vary directly with the value of *date_col*, because for every change in the value of *date_col*, the value of the expression changes in a consistent manner. The variance of the expression `YEAR(date_col)` with respect to *date_col* is not quite as direct as that of `TO_DAYS(date_col)`, because not every possible change in *date_col* produces an equivalent change in `YEAR(date_col)`. Even so, `YEAR(date_col)` is a good candidate for a hashing function, because it varies directly with a portion of *date_col* and there is no possible change in *date_col* that produces a disproportionate change in `YEAR(date_col)`.

By way of contrast, suppose that you have a column named *int_col* whose type is `INT`. Now consider the expression `POW(5-int_col, 3) + 6`. This would be a poor choice for a hashing function because a change in the value of *int_col* is not guaranteed to produce a proportional change in the value of the expression. Changing the value of *int_col* by a given amount can produce by widely different changes in the value of the expression. For example, changing *int_col* from 5 to 6 produces a change of -1 in the value of the expression, but changing the value of *int_col* from 6 to 7 produces a change of -7 in the expression value.

In other words, the more closely the graph of the column value *versus* the value of the expression follows a straight line as traced by the equation $y=nx$ where *n* is some nonzero constant, the better the expression is suited to hashing. This has to do with the fact that the more nonlinear an expression is, the more uneven the distribution of data among the partitions it tends to produce.

In theory, pruning is also possible for expressions involving more than one column value, but determining which of such expressions are suitable can be quite difficult and time-consuming. For this reason, the use of hashing expressions involving multiple columns is not particularly recommended.

When `PARTITION BY HASH` is used, MySQL determines which partition of *num* partitions to use based on the modulus of the result of the user function. In other words, for an expression *expr*, the partition in which the record is stored is partition number *N*, where $N = \text{MOD}(\text{expr}, \text{num})$. For example, suppose table `t1` is defined as follows, so that it has 4 partitions:

```
CREATE TABLE t1 (col1 INT, col2 CHAR(5), col3 DATE)
PARTITION BY HASH( YEAR(col3) )
PARTITIONS 4;
```

If you insert a record into `t1` whose `col3` value is `'2005-09-15'`, then the partition in which it is stored is determined as follows:

```
MOD(YEAR('2005-09-01'),4)
= MOD(2005,4)
= 1
```

MySQL 5.1 also supports a variant of `HASH` partitioning known as *linear hashing* which employs a more complex algorithm for determining the placement of new rows inserted into the partitioned table. See [Section 16.2.3.1, “LINEAR HASH Partitioning”](#), for a description of this algorithm.

The user function is evaluated each time a record is inserted or updated. It may also — depending on the circumstances — be evaluated when records are deleted.

Note: If the table to be partitioned has a `UNIQUE` key, then any columns supplied as arguments to the `HASH` user function or to the `KEY`'s `column_list` must be part of that key. **Exception:** This restriction does not apply to tables using the `NDBCluster` storage engine.

16.2.3.1. LINEAR HASH Partitioning

MySQL also supports linear hashing, which differs from regular hashing in that linear hashing utilizes a linear powers-of-two algorithm whereas regular hashing employs the modulus of the hashing function's value.

Syntactically, the only difference between linear-hash partitioning and regular hashing is the addition of the `LINEAR` keyword in the `PARTITION BY` clause, as shown here:

```
CREATE TABLE employees (
  id INT NOT NULL,
  fname VARCHAR(30),
  lname VARCHAR(30),
  hired DATE NOT NULL DEFAULT '1970-01-01',
  separated DATE NOT NULL DEFAULT '9999-12-31',
  job_code INT,
  store_id INT
)
PARTITION BY LINEAR HASH( YEAR(hired) )
PARTITIONS 4;
```

Given an expression `expr`, the partition in which the record is stored when linear hashing is used is partition number `N` from among `num` partitions, where `N` is derived according to the following algorithm:

1. Find the next power of 2 greater than `num`. We call this value `V`; it can be calculated as:

```
V = POWER(2, CEILING(LOG(2, num)))
```

(For example, suppose that `num` is 13. Then `LOG(2, 13)` is 3.7004397181411. `CEILING(3.7004397181411)` is 4, and `V = POWER(2, 4)`, which is 16.)

2. Set `N = F(column_list) & (V - 1)`.
3. While `N >= num`:
 - Set `V = CEIL(V / 2)`
 - Set `N = N & (V - 1)`

For example, suppose that the table `t1`, using linear hash partitioning and having 6 partitions, is created using this statement:

```
CREATE TABLE t1 (col1 INT, col2 CHAR(5), col3 DATE)
PARTITION BY LINEAR HASH( YEAR(col3) )
PARTITIONS 6;
```

Now assume that you want to insert two records into `t1` having the `col3` column values '2003-04-14' and '1998-10-19'. The partition number for the first of these is determined as follows:

```
V = POWER(2, CEILING( LOG(2,7) )) = 8
N = YEAR('2003-04-14') & (8 - 1)
  = 2003 & 7
  = 3
(3 >= 6 is FALSE: record stored in partition #3)
```

The number of the partition where the second record is stored is calculated as shown here:

```
V = 8
N = YEAR('1998-10-19') & (8-1)
  = 1998 & 7
  = 6
(6 >= 6 is TRUE: additional step required)
N = 6 & CEILING(5 / 2)
  = 6 & 3
  = 2
(2 >= 6 is FALSE: record stored in partition #2)
```

The advantage in partitioning by linear hash is that the adding, dropping, merging, and splitting of partitions is made much faster, which can be beneficial when dealing with tables containing extremely large amounts (terabytes) of data. The disadvantage is that data is less likely to be evenly distributed between partitions as compared with the distribution obtained using regular hash partitioning.

16.2.4. KEY Partitioning

Partitioning by key is similar to partitioning by hash, except that where hash partitioning employs a user-defined expression, the hashing function for key partitioning is supplied by the MySQL server. MySQL Cluster uses `MD5()` for this purpose; for tables using other storage engines, the server employs its own internal hashing function which is based on the same algorithm as `PASSWORD()`.

The syntax rules for `CREATE TABLE ... PARTITION BY KEY` are similar to those for creating a table that is partitioned by hash. The major differences are that:

- `KEY` is used rather than `HASH`.
- `KEY` takes only a list of one or more column names. Beginning with MySQL 5.1.5, the column or columns used as the partitioning key must comprise part or all of the table's primary key, if the table has one.

Beginning with MySQL 5.1.6, `KEY` takes a list of zero or more column names. Where no column name is specified as the partitioning key, the table's primary key is used, if there is one. For example, the following `CREATE TABLE` statement is valid in MySQL 5.1.6 or later:

```
CREATE TABLE k1 (
  id INT NOT NULL PRIMARY KEY,
  name VARCHAR(20)
)
PARTITION BY KEY()
PARTITIONS 2;
```

If there is no primary key but there is a unique key, then the unique key is used for the partitioning key:

```
CREATE TABLE k1 (
  id INT NOT NULL,
  name VARCHAR(20),
  UNIQUE KEY (id)
)
PARTITION BY KEY()
PARTITIONS 2;
```

However, if the unique key column were not defined as `NOT NULL`, then the previous statement would fail.

In both of these cases, the partitioning key is the `id` column, even though it is not shown in the output of `SHOW CREATE TABLE` or in the `PARTITION_EXPRESSION` column of the `INFORMATION_SCHEMA.PARTITIONS` table.

Unlike the case with other partitioning types, columns used for partitioning by `KEY` are not restricted to integer or `NULL` values. For example, the following `CREATE TABLE` statement is valid:

```
CREATE TABLE tml (
  s1 CHAR(32) PRIMARY KEY
)
PARTITION BY KEY(s1)
PARTITIONS 10;
```

The preceding statement would *not* be valid, were a different partitioning type to be specified. (**Note:** In this case, simply using `PARTITION BY KEY()` would also be valid and have the same effect as `PARTITION BY KEY(s1)`, since `s1` is the table's primary key.)

For additional information about this issue, see [Section 16.5, “Restrictions and Limitations on Partitioning”](#).

Note: Also beginning with MySQL 5.1.6, tables using the `NDB Cluster` storage engine are implicitly partitioned by `KEY`, again using the table's primary key as the partitioning key. In the event that the Cluster table has no explicit primary key, the “hidden” primary key generated by the `NDB` storage engine for each Cluster table is used as the partitioning key.

Important: For a key-partitioned table using any MySQL storage engine other than `NDB Cluster`, you cannot execute an `ALTER TABLE DROP PRIMARY KEY`, as doing so generates the error `ERROR 1466 (HY000): Field in list of fields for partition function not found in table`. This is not an issue for MySQL Cluster tables which are partitioned by `KEY`; in such cases, the table is reorganized using the “hidden” primary key as the table's new partitioning key. See [Chapter 15, *MySQL Cluster*](#).

It is also possible to partition a table by linear key. Here is a simple example:

```
CREATE TABLE tk (
  col1 INT NOT NULL,
  col2 CHAR(5),
  col3 DATE
)
PARTITION BY LINEAR KEY (col1)
PARTITIONS 3;
```

Using `LINEAR` has the same effect on `KEY` partitioning as it does on `HASH` partitioning, with the partition number being derived using a powers-of-two algorithm rather than modulo arithmetic. See [Section 16.2.3.1, “LINEAR HASH Partitioning”](#), for a description of this algorithm and its implications.

16.2.5. Subpartitioning

Subpartitioning — also known as *composite partitioning* — is the further division of each partition in a partitioned table. For example, consider the following `CREATE TABLE` statement:

```
CREATE TABLE ts (id INT, purchased DATE)
PARTITION BY RANGE( YEAR(purchased) )
SUBPARTITION BY HASH( TO_DAYS(purchased) )
SUBPARTITIONS 2 (
    PARTITION p0 VALUES LESS THAN (1990),
    PARTITION p1 VALUES LESS THAN (2000),
    PARTITION p2 VALUES LESS THAN MAXVALUE
);
```

Table `ts` has 3 `RANGE` partitions. Each of these partitions — `p0`, `p1`, and `p2` — is further divided into 2 subpartitions. In effect, the entire table is divided into $3 * 2 = 6$ partitions. However, due to the action of the `PARTITION BY RANGE` clause, the first 2 of these store only those records with a value less than 1990 in the `purchased` column.

In MySQL 5.1, it is possible to subpartition tables that are partitioned by `RANGE` or `LIST`. Subpartitions may use either `HASH` or `KEY` partitioning. This is also known as *composite partitioning*.

It is also possible to define subpartitions explicitly using `SUBPARTITION` clauses to specify options for individual subpartitions. For example, a more verbose fashion of creating the same table `ts` as shown in the previous example would be:

```
CREATE TABLE ts (id INT, purchased DATE)
PARTITION BY RANGE( YEAR(purchased) )
SUBPARTITION BY HASH( TO_DAYS(purchased) ) (
    PARTITION p0 VALUES LESS THAN (1990) (
        SUBPARTITION s0,
        SUBPARTITION s1
    ),
    PARTITION p1 VALUES LESS THAN (2000) (
        SUBPARTITION s2,
        SUBPARTITION s3
    ),
    PARTITION p2 VALUES LESS THAN MAXVALUE (
        SUBPARTITION s4,
        SUBPARTITION s5
    )
);
```

Some syntactical items of note:

- Each partition must have the same number of subpartitions.
- If you explicitly define any subpartitions using `SUBPARTITION` on any partition of a partitioned table, you must define them all. In other words, the following statement will fail:

```
CREATE TABLE ts (id INT, purchased DATE)
PARTITION BY RANGE( YEAR(purchased) )
SUBPARTITION BY HASH( TO_DAYS(purchased) ) (
    PARTITION p0 VALUES LESS THAN (1990) (
        SUBPARTITION s0,
        SUBPARTITION s1
    ),
    PARTITION p1 VALUES LESS THAN (2000),
    PARTITION p2 VALUES LESS THAN MAXVALUE (
        SUBPARTITION s2,
        SUBPARTITION s3
    )
);
```

This statement would still fail even if it included a `SUBPARTITIONS 2` clause.

- Each `SUBPARTITION` clause must include (at a minimum) a name for the subpartition. Otherwise, you may set any desired option for the subpartition or allow it to assume its default setting for that

option.

- In MySQL 5.1.7 and earlier, names of subpartitions must be unique within each partition, but do not have to be unique within the table as a whole. Beginning with MySQL 5.1.8, subpartition names must be unique across the entire table. For example, the following `CREATE TABLE` statement is valid in MySQL 5.1.8 and later:

```
CREATE TABLE ts (id INT, purchased DATE)
  PARTITION BY RANGE( YEAR(purchased) )
  SUBPARTITION BY HASH( TO_DAYS(purchased) ) (
    PARTITION p0 VALUES LESS THAN (1990) (
      SUBPARTITION s0,
      SUBPARTITION s1
    ),
    PARTITION p1 VALUES LESS THAN (2000) (
      SUBPARTITION s2,
      SUBPARTITION s3
    ),
    PARTITION p2 VALUES LESS THAN MAXVALUE (
      SUBPARTITION s4,
      SUBPARTITION s5
    )
  );
```

(The previous statement is also valid for versions of MySQL prior to 5.1.8.)

Subpartitions can be used with especially large tables to distribute data and indexes across many disks. Suppose that you have 6 disks mounted as `/disk0`, `/disk1`, `/disk2`, and so on. Now consider the following example:

```
CREATE TABLE ts (id INT, purchased DATE)
  PARTITION BY RANGE( YEAR(purchased) )
  SUBPARTITION BY HASH( TO_DAYS(purchased) ) (
    PARTITION p0 VALUES LESS THAN (1990) (
      SUBPARTITION s0
        DATA DIRECTORY = '/disk0/data'
        INDEX DIRECTORY = '/disk0/idx',
      SUBPARTITION s1
        DATA DIRECTORY = '/disk1/data'
        INDEX DIRECTORY = '/disk1/idx'
    ),
    PARTITION p1 VALUES LESS THAN (2000) (
      SUBPARTITION s2
        DATA DIRECTORY = '/disk2/data'
        INDEX DIRECTORY = '/disk2/idx',
      SUBPARTITION s3
        DATA DIRECTORY = '/disk3/data'
        INDEX DIRECTORY = '/disk3/idx'
    ),
    PARTITION p2 VALUES LESS THAN MAXVALUE (
      SUBPARTITION s4
        DATA DIRECTORY = '/disk4/data'
        INDEX DIRECTORY = '/disk4/idx',
      SUBPARTITION s5
        DATA DIRECTORY = '/disk5/data'
        INDEX DIRECTORY = '/disk5/idx'
    )
  );
```

In this case, a separate disk is used for the data and for the indexes of each `RANGE`. Many other variations are possible; another example might be:

```
CREATE TABLE ts (id INT, purchased DATE)
  PARTITION BY RANGE(YEAR(purchased))
  SUBPARTITION BY HASH( TO_DAYS(purchased) ) (
    PARTITION p0 VALUES LESS THAN (1990) (
      SUBPARTITION s0a
        DATA DIRECTORY = '/disk0'
        INDEX DIRECTORY = '/disk1',
      SUBPARTITION s0b
        DATA DIRECTORY = '/disk2'
```

```

        INDEX DIRECTORY = '/disk3'
    ),
    PARTITION p1 VALUES LESS THAN (2000) (
        SUBPARTITION s1a
            DATA DIRECTORY = '/disk4/data'
            INDEX DIRECTORY = '/disk4/idx',
        SUBPARTITION s1b
            DATA DIRECTORY = '/disk5/data'
            INDEX DIRECTORY = '/disk5/idx'
    ),
    PARTITION p2 VALUES LESS THAN MAXVALUE (
        SUBPARTITION s2a,
        SUBPARTITION s2b
    )
);

```

Here, the storage is as follows:

- Rows with `purchased` dates from before 1990 take up a vast amount of space, so are split up 4 ways, with a separate disk dedicated to the data and to the indexes for each of the two subpartitions (`s0a` and `s0b`) making up partition `p0`. In other words:
 - The data for subpartition `s0a` is stored on `/disk0`.
 - The indexes for subpartition `s0a` are stored on `/disk1`.
 - The data for subpartition `s0b` is stored on `/disk2`.
 - The indexes for subpartition `s0b` are stored on `/disk3`.
- Rows containing dates ranging from 1990 to 1999 (partition `p1`) do not require as much room as those from before 1990. These are split between 2 disks (`/disk4` and `/disk5`) rather than 4 disks as with the legacy records stored in `p0`:
 - Data and indexes belonging to `p1`'s first subpartition (`s1a`) are stored on `/disk4` — the data in `/disk4/data`, and the indexes in `/disk4/idx`.
 - Data and indexes belonging to `p1`'s second subpartition (`s1b`) are stored on `/disk5` — the data in `/disk5/data`, and the indexes in `/disk5/idx`.
- Rows reflecting dates from the year 2000 to the present (partition `p2`) do not take up as much space as required by either of the two previous ranges. Currently, it is sufficient to store all of these in the default location.

In future, when the number of purchases for the decade beginning with the year 2000 grows to a point where the default location no longer provides sufficient space, the corresponding rows can be moved using an `ALTER TABLE ... REORGANIZE PARTITION` statement. See [Section 16.3, “Partition Management”](#), for an explanation of how this can be done.

16.2.6. How MySQL Partitioning Handles `NULL` Values

Partitioning in MySQL does nothing to disallow `NULL` as the value of a partitioning expression, whether it is a column value or the value of a user-supplied expression. Even though it is permitted to use `NULL` as the value of an expression that must otherwise yield an integer, it is important to keep in mind that `NULL` is not a number. Beginning version 5.1.8, MySQL Partitioning treats `NULL` as being less than any non-`NULL` value, just as `ORDER BY` does.

Because of this, this treatment of `NULL` varies between partitioning of different types, and may produce behavior which you do not expect if you are not prepared for it. This being the case, we discuss in this section how each MySQL partitioning types handles `NULL` values when determining the partition in

which a row should be stored, and provide examples for each.

If you insert a row into a table partitioned by `RANGE` such that the column value used to determine the partition is `NULL`, the row is inserted into the lowest partition. For example, consider these two tables, created and populated as follows:

```
mysql> CREATE TABLE t1 (
->   c1 INT,
->   c2 VARCHAR(20)
-> )
-> PARTITION BY RANGE(c1) (
->   PARTITION p0 VALUES LESS THAN (0),
->   PARTITION p1 VALUES LESS THAN (10),
->   PARTITION p2 VALUES LESS THAN MAXVALUE
-> );
Query OK, 0 rows affected (0.09 sec)

mysql> CREATE TABLE t1 (
->   c1 INT,
->   c2 VARCHAR(20)
-> )
-> PARTITION BY RANGE(c1) (
->   PARTITION p0 VALUES LESS THAN (-5),
->   PARTITION p1 VALUES LESS THAN (0),
->   PARTITION p1 VALUES LESS THAN (10),
->   PARTITION p2 VALUES LESS THAN MAXVALUE
-> );
Query OK, 0 rows affected (0.09 sec)

mysql> INSERT INTO t1 VALUES (NULL, 'mothra');
Query OK, 1 row affected (0.00 sec)

mysql> INSERT INTO t2 VALUES (NULL, 'mothra');
Query OK, 1 row affected (0.00 sec)

mysql> SELECT * FROM t1;
+-----+-----+
| id | name |
+-----+-----+
| NULL | mothra |
+-----+-----+
1 row in set (0.00 sec)

mysql> SELECT * FROM t2;
+-----+-----+
| id | name |
+-----+-----+
| NULL | mothra |
+-----+-----+
1 row in set (0.00 sec)
```

You can see which partitions the rows are stored in by inspecting the filesystem and comparing the sizes of the `.MYD` files corresponding to the partitions:

```
/var/lib/mysql/test> ls -l *.MYD
-rw-rw---- 1 mysql mysql 20 2006-03-10 03:27 t1#P#p0.MYD
-rw-rw---- 1 mysql mysql 0 2006-03-10 03:17 t1#P#p1.MYD
-rw-rw---- 1 mysql mysql 0 2006-03-10 03:17 t1#P#p2.MYD
-rw-rw---- 1 mysql mysql 20 2006-03-10 03:27 t2#P#p0.MYD
-rw-rw---- 1 mysql mysql 0 2006-03-10 03:17 t2#P#p1.MYD
-rw-rw---- 1 mysql mysql 0 2006-03-10 03:17 t2#P#p2.MYD
-rw-rw---- 1 mysql mysql 0 2006-03-10 03:17 t2#P#p3.MYD
```

(Partition files are named according to the format `table_name#P#partition_name.extension`, so that `t1#P#p0.MYD` is the file in which data belonging to partition `p0` of table `t1` is stored. **Note:** Prior to MySQL 5.1.5, these files would have been named `t1_p0.MYD` and `t2_p0.MYD`, respectively. See [Section D.1.7, “Changes in release 5.1.6 \(01 February 2006\)”](#) and [Bug#13437](#) [<http://bugs.mysql.com/13437>] for information regarding how this change impacts upgrades.)

You can also demonstrate that these rows were stored in the lowest partition of the each table by dropping these partitions, and then re-running the `SELECT` statements:

```
mysql> ALTER TABLE t1 DROP PARTITION p0;
```

```
Query OK, 0 rows affected (0.16 sec)

mysql> ALTER TABLE t2 DROP PARTITION p0;
Query OK, 0 rows affected (0.16 sec)

mysql> SELECT * FROM t1;
Empty set (0.00 sec)

mysql> SELECT * FROM t2;
Empty set (0.00 sec)
```

(For more information on `ALTER TABLE ... DROP PARTITION`, see [Section 13.1.2, “ALTER TABLE Syntax”](#).)

Such treatment also holds true for partitioning expressions that use SQL functions. Suppose that we have a table such as this one:

```
CREATE TABLE tndate (
  id INT,
  dt DATE
)
PARTITION BY RANGE( YEAR(dt) ) (
  PARTITION p0 VALUES LESS THAN (1990),
  PARTITION p1 VALUES LESS THAN (2000),
  PARTITION p2 VALUES LESS THAN MAXVALUE
);
```

As with other MySQL functions, `YEAR(NULL)` returns `NULL`. A row with a `dt` column value of `NULL` is treated as though the partitioning expression evaluated to a value less than any other value, and so is inserted into partition `p0`.

A table that is partitioned by `LIST` admits `NULL` values if and only if one of its partitions is defined using that value-list that contains `NULL`. The converse of this is that a table partitioned by `LIST` which does not explicitly use `NULL` in a value list rejects rows resulting in a `NULL` value for the partitioning expression, as shown in this example:

```
mysql> CREATE TABLE ts1 (
->   c1 INT,
->   c2 VARCHAR(20)
-> )
-> PARTITION BY LIST(c1) (
->   PARTITION p0 VALUES IN (0, 3, 6),
->   PARTITION p1 VALUES IN (1, 4, 7),
->   PARTITION p2 VALUES IN (2, 5, 8)
-> );
Query OK, 0 rows affected (0.01 sec)

mysql> INSERT INTO ts1 VALUES (9, 'mothra');
ERROR 1504 (HY000): Table has no partition for value 9

mysql> INSERT INTO ts1 VALUES (NULL, 'mothra');
ERROR 1504 (HY000): Table has no partition for value NULL
```

Only rows having a `c1` value between 0 and 8 inclusive can be inserted into `ts1`. `NULL` falls outside this range, just like the number 9. We can create tables `ts2` and `ts3` having value lists containing `NULL`, as shown here:

```
mysql> CREATE TABLE ts2 (
->   c1 INT,
->   c2 VARCHAR(20)
-> )
-> PARTITION BY LIST(c1) (
->   PARTITION p0 VALUES IN (0, 3, 6),
->   PARTITION p1 VALUES IN (1, 4, 7),
->   PARTITION p2 VALUES IN (2, 5, 8),
->   PARTITION p3 VALUES IN (NULL)
-> );
Query OK, 0 rows affected (0.01 sec)

mysql> CREATE TABLE ts3 (
->   c1 INT,
```

```

->     c2 VARCHAR(20)
-> )
-> PARTITION BY LIST(c1) (
->     PARTITION p0 VALUES IN (0, 3, 6),
->     PARTITION p1 VALUES IN (1, 4, 7, NULL),
->     PARTITION p2 VALUES IN (2, 5, 8)
-> );
Query OK, 0 rows affected (0.01 sec)

```

When defining value lists for partitioning, you can treat `NULL` just as you would any other value, and so `VALUES IN (NULL)` and `VALUES IN (1, 4, 7, NULL)` are both valid (as are `VALUES IN (1, NULL, 4, 7)`, `VALUES IN (NULL, 1, 4, 7)`, and so on). You can insert a row having `NULL` for column `c1` into each of the tables `ts2` and `ts3`:

```

mysql> INSERT INTO ts2 VALUES (NULL, 'mothra');
Query OK, 1 row affected (0.00 sec)

mysql> INSERT INTO ts3 VALUES (NULL, 'mothra');
Query OK, 1 row affected (0.00 sec)

```

By inspecting the filesystem, you can verify that the first of these statements inserted a new row into partition `p3` of table `ts2`, and that the second statement inserted a new row into partition `p1` of table `ts3`:

```

/var/lib/mysql/test> ls -l ts2*.MYD
-rw-rw---- 1 mysql mysql 0 2006-03-10 10:35 ts2#P#p0.MYD
-rw-rw---- 1 mysql mysql 0 2006-03-10 10:35 ts2#P#p1.MYD
-rw-rw---- 1 mysql mysql 0 2006-03-10 10:35 ts2#P#p2.MYD
-rw-rw---- 1 mysql mysql 20 2006-03-10 10:35 ts2#P#p3.MYD

/var/lib/mysql/test> ls -l ts3*.MYD
-rw-rw---- 1 mysql mysql 0 2006-03-10 10:36 ts3#P#p0.MYD
-rw-rw---- 1 mysql mysql 20 2006-03-10 10:36 ts3#P#p1.MYD
-rw-rw---- 1 mysql mysql 0 2006-03-10 10:36 ts3#P#p2.MYD

```

As in earlier examples, we assume the use of the `bash` shell on a Unix operating system for listing files; use whatever your platform provides in this regard. For example, if you are using a DOS shell on a Windows operating system, the equivalent for the last listing might be obtained by running the command `dir ts3*.MYD` in the directory `C:\Program Files\MySQL\MySQL Server 5.1\data\test`.

As shown earlier in this section, you can also verify which partitions were used for storing the values by deleting them and then performing a `SELECT`.

`NULL` is handled somewhat differently for tables partitioned by `HASH` or `KEY`. In these cases, any partition expression that yields a `NULL` value is treated as though its return value were zero. We can verify this behavior by examining the effects on the filesystem of creating a table partitioned by `HASH` and populating it with a record containing appropriate values. Suppose that you have a table `th`, created in the `test` database, using this statement:

```

mysql> CREATE TABLE th (
->     c1 INT,
->     c2 VARCHAR(20)
-> )
-> PARTITION BY HASH(c1)
-> PARTITIONS 2;
Query OK, 0 rows affected (0.00 sec)

```

Assuming an RPM installation of MySQL on Linux, this statement creates two `.MYD` files in `/var/lib/mysql/test`, which can be viewed in the `bash` shell as follows:

```

/var/lib/mysql/test> ls th*.MYD -l
-rw-rw---- 1 mysql mysql 0 2005-11-04 18:41 th#P#p0.MYD
-rw-rw---- 1 mysql mysql 0 2005-11-04 18:41 th#P#p1.MYD

```

Note that the size of each file is 0 bytes. Now insert a row into `th` whose `c1` column value is `NULL`, and verify that this row was inserted:

```
mysql> INSERT INTO th VALUES (NULL, 'mothra');
Query OK, 1 row affected (0.00 sec)

mysql> SELECT * FROM th;
+-----+-----+
| c1    | c2    |
+-----+-----+
| NULL  | mothra |
+-----+-----+
1 row in set (0.01 sec)
```

Recall that for any integer `N`, the value of `NULL MOD N` is always `NULL`. For tables that are partitioned by `HASH` or `KEY`, this result is treated for determining the correct partition as `0`. Returning to the system shell (still assuming `bash` for this purpose), we can see that the value was inserted into the first partition (named `p0` by default) by listing the data files once again:

```
var/lib/mysql/test> ls *.MYD -l
-rw-rw---- 1 mysql mysql 20 2005-11-04 18:44 th#P#p0.MYD
-rw-rw---- 1 mysql mysql 0 2005-11-04 18:41 th#P#p1.MYD
```

You can see that the `INSERT` statement modified only the file `th#P#p0.MYD` (increasing its size on disk), without affecting the other data file.

Important: Prior to MySQL 5.1.8, `RANGE` partitioning treated a partitioning expression value of `NULL` as a zero with respect to determining placement (the only way to circumvent this was to design tables so as not to allow nulls, usually by declaring columns `NOT NULL`). If you have a `RANGE` partitioning scheme that depends on this earlier behavior, you will need to re-implement it when upgrading to MySQL 5.1.8 or later.

16.3. Partition Management

MySQL 5.1 provides a number of ways to modify partitioned tables. It is possible to add, drop, redefine, merge, or split existing partitions. All of these actions can be carried out using the partitioning extensions to the `ALTER TABLE` command (see [Section 13.1.2, “ALTER TABLE Syntax”](#), for syntax definitions). There are also ways to obtain information about partitioned tables and partitions. We discuss these topics in the sections that follow.

- For information about partition management in tables partitioned by `RANGE` or `LIST`, see [Section 16.3.1, “Management of RANGE and LIST Partitions”](#).
- For a discussion of managing `HASH` and `KEY` partitions, see [Section 16.3.2, “Management of HASH and KEY Partitions”](#).
- See [Section 16.3.4, “Obtaining Information About Partitions”](#), for a discussion of mechanisms provided in MySQL 5.1 for obtaining information about partitioned tables and partitions.
- For a discussion of performing maintenance operations on partitions, see [Section 16.3.3, “Maintenance of Partitions”](#).

Note: In MySQL 5.1, all partitions of a partitioned table must have the same number of subpartitions, and it is not possible to change the subpartitioning once the table has been created.

The statement `ALTER TABLE ... PARTITION BY ...` is available and is functional beginning with MySQL 5.1.6; previously in MySQL 5.1, this was accepted as valid syntax, but the statement did nothing.

To change a table's partitioning scheme, it is necessary only to use the `ALTER TABLE` command with a `partition_options` clause. This clause has the same syntax as that as used with `CREATE TABLE` for creating a partitioned table, and always begins with the keywords `PARTITION BY`. For example, suppose that you have a table partitioned by range using the following `CREATE TABLE` statement:

```
CREATE TABLE trb3 (id INT, name VARCHAR(50), purchased DATE)
PARTITION BY RANGE( YEAR(purchased) ) (
    PARTITION p0 VALUES LESS THAN (1990),
    PARTITION p1 VALUES LESS THAN (1995),
    PARTITION p2 VALUES LESS THAN (2000),
    PARTITION p3 VALUES LESS THAN (2005)
);
```

To repartition this table so that it is partitioned by key into two partitions using the `id` column value as the basis for the key, you can use this statement:

```
ALTER TABLE trb3 PARTITION BY KEY(id) PARTITIONS 2;
```

This has the same effect on the structure of the table as dropping the table and re-creating it using `CREATE TABLE trb3 PARTITION BY KEY(id) PARTITIONS 2;`

Important: In MySQL 5.1.7 and earlier MySQL 5.1 releases, `ALTER TABLE ... ENGINE = ...` removed all partitioning from the affected table. Beginning with MySQL 5.1.8, this statement changes only the storage engine used by the table, and leaves the table's partitioning scheme intact. As of MySQL 5.1.8, use `ALTER TABLE ... REMOVE PARTITIONING` to remove a table's partitioning. See [Section 13.1.2, “ALTER TABLE Syntax”](#).

16.3.1. Management of RANGE and LIST Partitions

Range and list partitions are very similar with regard to how the adding and dropping of partitions are handled. For this reason we discuss the management of both sorts of partitioning in this section. For information about working with tables that are partitioned by hash or key, see [Section 16.3.2, “Management of HASH and KEY Partitions”](#). Dropping a `RANGE` or `LIST` partition is more straightforward than adding one, so we discuss this first.

Dropping a partition from a table that is partitioned by either `RANGE` or by `LIST` can be accomplished using the `ALTER TABLE` statement with a `DROP PARTITION` clause. Here is a very basic example, which supposes that you have already created a table which is partitioned by range and then populated with 10 records using the following `CREATE TABLE` and `INSERT` statements:

```
mysql> CREATE TABLE tr (id INT, name VARCHAR(50), purchased DATE)
->     PARTITION BY RANGE( YEAR(purchased) ) (
->         PARTITION p0 VALUES LESS THAN (1990),
->         PARTITION p1 VALUES LESS THAN (1995),
->         PARTITION p2 VALUES LESS THAN (2000),
->         PARTITION p3 VALUES LESS THAN (2005)
->     );
Query OK, 0 rows affected (0.01 sec)

mysql> INSERT INTO tr VALUES
->     (1, 'desk organiser', '2003-10-15'),
->     (2, 'CD player', '1993-11-05'),
->     (3, 'TV set', '1996-03-10'),
->     (4, 'bookcase', '1982-01-10'),
->     (5, 'exercise bike', '2004-05-09'),
->     (6, 'sofa', '1987-06-05'),
->     (7, 'popcorn maker', '2001-11-22'),
->     (8, 'aquarium', '1992-08-04'),
->     (9, 'study desk', '1984-09-16'),
->     (10, 'lava lamp', '1998-12-25');
Query OK, 10 rows affected (0.01 sec)
```

You can see which items should have been inserted into partition `p2` as shown here:

```
mysql> SELECT * FROM tr
-> WHERE purchased BETWEEN '1995-01-01' AND '1999-12-31';
+-----+-----+-----+
| id   | name   | purchased |
+-----+-----+-----+
| 3    | TV set | 1996-03-10 |
| 10   | lava lamp | 1998-12-25 |
+-----+-----+-----+
2 rows in set (0.00 sec)
```

To drop the partition named `p2`, execute the following command:

```
mysql> ALTER TABLE tr DROP PARTITION p2;
Query OK, 0 rows affected (0.03 sec)
```

Note: In MySQL 5.1, the `NDB Cluster` storage engine does not support `ALTER TABLE ... DROP PARTITION`. It does, however, support the other partitioning-related extensions to `ALTER TABLE` that are described in this chapter.

It is very important to remember that, *when you drop a partition, you also delete all the data that was stored in that partition*. You can see that this is the case by re-running the previous `SELECT` query:

```
mysql> SELECT * FROM tr WHERE purchased
-> BETWEEN '1995-01-01' AND '1999-12-31';
Empty set (0.00 sec)
```

Because of this, the requirement was added in MySQL 5.1.10 that you have the `DROP` privilege for a table before you can execute `ALTER TABLE ... DROP PARTITION` on that table.

If you wish to drop all data from all partitions while preserving the table definition and its partitioning scheme, use the `TRUNCATE TABLE` command. (See [Section 13.2.9, “TRUNCATE Syntax”](#).)

If you intend to change the partitioning of a table *without* losing data, use `ALTER TABLE ... REORGANIZE PARTITION` instead. See below or in [Section 13.1.2, “ALTER TABLE Syntax”](#), for information about `REORGANIZE PARTITION`.

If you now execute a `SHOW CREATE TABLE` command, you can see how the partitioning makeup of the table has been changed:

```
mysql> SHOW CREATE TABLE tr\G
***** 1. row *****
      Table: tr
Create Table: CREATE TABLE `tr` (
  `id` int(11) default NULL,
  `name` varchar(50) default NULL,
  `purchased` date default NULL
) ENGINE=MyISAM DEFAULT CHARSET=latin1
PARTITION BY RANGE ( YEAR(purchased) ) (
  PARTITION p0 VALUES LESS THAN (1990) ENGINE = MyISAM,
  PARTITION p1 VALUES LESS THAN (1995) ENGINE = MyISAM,
  PARTITION p3 VALUES LESS THAN (2005) ENGINE = MyISAM
)
1 row in set (0.01 sec)
```

When you insert new rows into the changed table with `purchased` column values between `'1995-01-01'` and `'2004-12-31'` inclusive, those rows will be stored in partition `p3`. You can verify this as follows:

```
mysql> INSERT INTO tr VALUES (11, 'pencil holder', '1995-07-12');
Query OK, 1 row affected (0.00 sec)

mysql> SELECT * FROM tr WHERE purchased
-> BETWEEN '1995-01-01' AND '2004-12-31';
+-----+-----+-----+
| id   | name       | purchased |
+-----+-----+-----+
```

```

+----+-----+-----+
| 11 | pencil holder | 1995-07-12 |
| 1  | desk organiser | 2003-10-15 |
| 5  | exercise bike  | 2004-05-09 |
| 7  | popcorn maker  | 2001-11-22 |
+----+-----+-----+
4 rows in set (0.00 sec)

mysql> ALTER TABLE tr DROP PARTITION p3;
Query OK, 0 rows affected (0.03 sec)

mysql> SELECT * FROM tr WHERE purchased
-> BETWEEN '1995-01-01' AND '2004-12-31';
Empty set (0.00 sec)

```

Note that the number of rows dropped from the table as a result of `ALTER TABLE ... DROP PARTITION` is not reported by the server as it would be by the equivalent `DELETE` query.

Dropping `LIST` partitions uses exactly the same `ALTER TABLE ... DROP PARTITION` syntax as used for dropping `RANGE` partitions. However, there is one important difference in the effect this has on your use of the table afterward: You can no longer insert into the table any rows having any of the values that were included in the value list defining the deleted partition. (See [Section 16.2.2](#), “`LIST Partitioning`”, for an example.)

To add a new range or list partition to a previously partitioned table, use the `ALTER TABLE ... ADD PARTITION` statement. For tables which are partitioned by `RANGE`, this can be used to add a new range to the end of the list of existing partitions. For example, suppose that you have a partitioned table containing membership data for your organisation, which is defined as follows:

```

CREATE TABLE members (
  id INT,
  fname VARCHAR(25),
  lname VARCHAR(25),
  dob DATE
)
PARTITION BY RANGE( YEAR(dob) ) (
  PARTITION p0 VALUES LESS THAN (1970),
  PARTITION p1 VALUES LESS THAN (1980),
  PARTITION p2 VALUES LESS THAN (1990)
);

```

Suppose further that the minimum age for members is 16. As the calendar approaches the end of 2005, you realize that you will soon be admitting members who were born in 1990 (and later in years to come). You can modify the `members` table to accommodate new members born in the years 1990-1999 as shown here:

```
ALTER TABLE ADD PARTITION (PARTITION p3 VALUES LESS THAN (2000));
```

Important: With tables that are partitioned by range, you can use `ADD PARTITION` to add new partitions to the high end of the partitions list only. Trying to add a new partition in this manner between or before existing partitions will result in an error as shown here:

```

mysql> ALTER TABLE members
> ADD PARTITION (
> PARTITION p3 VALUES LESS THAN (1960));
ERROR 1463 (HY000): VALUES LESS THAN value must be strictly »
increasing for each partition

```

In a similar fashion, you can add new partitions to a table that is partitioned by `LIST`. For example, given a table defined like so:

```

CREATE TABLE tt (
  id INT,
  data INT
)
PARTITION BY LIST(data) (
  PARTITION p0 VALUES IN (5, 10, 15),
  PARTITION p1 VALUES IN (6, 12, 18)
)

```

```
);
```

You can add a new partition in which to store rows having the `data` column values 7, 14, and 21 as shown:

```
ALTER TABLE tt ADD PARTITION (PARTITION p2 VALUES IN (7, 14, 21));
```

Note that you *cannot* add a new `LIST` partition encompassing any values that are already included in the value list of an existing partition. If you attempt to do so, an error will result:

```
mysql> ALTER TABLE tt ADD PARTITION
> (PARTITION np VALUES IN (4, 8, 12));
ERROR 1465 (HY000): Multiple definition of same constant »
in list partitioning
```

Because any rows with the `data` column value 12 have already been assigned to partition `p1`, you cannot create a new partition on table `tt` that includes 12 in its value list. To accomplish this, you could drop `p1`, and add `np` and then a new `p1` with a modified definition. However, as discussed earlier, this would result in the loss of all data stored in `p1` — and it is often the case that this is not what you really want to do. Another solution might appear to be to make a copy of the table with the new partitioning and to copy the data into it using `CREATE TABLE ... SELECT ...`, then drop the old table and rename the new one, but this could be very time-consuming when dealing with a large amounts of data. This also might not be feasible in situations where high availability is a requirement.

Beginning with MySQL 5.1.6, you can add multiple partitions in a single `ALTER TABLE ... ADD PARTITION` statement as shown here:

```
CREATE TABLE employees (
  id INT NOT NULL,
  fname VARCHAR(50) NOT NULL,
  lname VARCHAR(50) NOT NULL,
  hired DATE NOT NULL
)
PARTITION BY RANGE( YEAR(hired) ) (
  PARTITION p1 VALUES LESS THAN (1991),
  PARTITION p2 VALUES LESS THAN (1996),
  PARTITION p3 VALUES LESS THAN (2001),
  PARTITION p4 VALUES LESS THAN (2005)
);

ALTER TABLE employees ADD PARTITION (
  PARTITION p5 VALUES LESS THAN (2010),
  PARTITION p6 VALUES LESS THAN MAXVALUE
);
```

Fortunately, MySQL's partitioning implementation provides ways to redefine partitions without losing data. Let us look first at a couple of simple examples involving `RANGE` partitioning. Recall the `members` table which is now defined as shown here:

```
mysql> SHOW CREATE TABLE members\G
***** 1. row *****
      Table: members
Create Table: CREATE TABLE `members` (
  `id` int(11) default NULL,
  `fname` varchar(25) default NULL,
  `lname` varchar(25) default NULL,
  `dob` date default NULL
) ENGINE=MyISAM DEFAULT CHARSET=latin1
PARTITION BY RANGE ( YEAR(dob) ) (
  PARTITION p0 VALUES LESS THAN (1970) ENGINE = MyISAM,
  PARTITION p1 VALUES LESS THAN (1980) ENGINE = MyISAM,
  PARTITION p2 VALUES LESS THAN (1990) ENGINE = MyISAM,
  PARTITION p3 VALUES LESS THAN (2000) ENGINE = MyISAM
)
```

Suppose that you would like to move all rows representing members born before 1960 into a separate partition. As we have already seen, this cannot be done using `ALTER TABLE ... ADD PARTITION`. However, you can use another partition-related extension to `ALTER TABLE` in order to accomplish this:

```
ALTER TABLE members REORGANIZE PARTITION p0 INTO (
  PARTITION s0 VALUES LESS THAN (1960),
  PARTITION s1 VALUES LESS THAN (1970)
);
```

In effect, this command splits partition `p0` into two new partitions `s0` and `s1`. It also moves the data that was stored in `p0` into the new partitions according to the rules embodied in the two `PARTITION ... VALUES ...` clauses, so that `s0` contains only those records for which `YEAR(dob)` is less than 1960 and `s1` contains those rows in which `YEAR(dob)` is greater than or equal to 1960 but less than 1970.

A `REORGANIZE PARTITION` clause may also be used for merging adjacent partitions. You can return the `members` table to its previous partitioning as shown here:

```
ALTER TABLE members REORGANIZE PARTITION s0,s1 INTO (
  PARTITION p0 VALUES LESS THAN (1970)
);
```

No data is lost in splitting or merging partitions using `REORGANIZE PARTITION`. In executing the above statement, MySQL moves all of the records that were stored in partitions `s0` and `s1` into partition `p0`.

The general syntax for `REORGANIZE PARTITION` is:

```
ALTER TABLE tbl_name
  REORGANIZE PARTITION partition_list
  INTO (partition_definitions);
```

Here, `tbl_name` is the name of the partitioned table, and `partition_list` is a comma-separated list of names of one or more existing partitions to be changed. `partition_definitions` is a comma-separated list of new partition definitions, which follow the same rules as for the `partition_definitions` list used in `CREATE TABLE` (see [Section 13.1.7, “CREATE TABLE Syntax”](#)). It should be noted that you are not limited to merging several partitions into one, or to splitting one partition into many, when using `REORGANIZE PARTITION`. For example, you can reorganize all four partitions of the `members` table into two, as follows:

```
ALTER TABLE members REORGANIZE PARTITION p0,p1,p2,p3 INTO (
  PARTITION m0 VALUES LESS THAN (1980),
  PARTITION m1 VALUES LESS THAN (2000)
);
```

You can also use `REORGANIZE PARTITION` with tables that are partitioned by `LIST`. Let us return to the problem of adding a new partition to the list-partitioned `tt` table and failing because the new partition had a value that was already present in the value-list of one of the existing partitions. We can handle this by adding a partition that contains only non-conflicting values, and then reorganizing the new partition and the existing one so that the value which was stored in the existing one is now moved to the new one:

```
ALTER TABLE tt ADD PARTITION (PARTITION np VALUES IN (4, 8));
ALTER TABLE tt REORGANIZE PARTITION p1,np INTO (
  PARTITION p1 VALUES IN (6, 18),
  PARTITION np VALUES in (4, 8, 12)
);
```

Here are some key points to keep in mind when using `ALTER TABLE ... REORGANIZE PARTI-`

ITION to repartition tables that are partitioned by **RANGE** or **LIST**:

- The **PARTITION** clauses used to determine the new partitioning scheme are subject to the same rules as those used with a **CREATE TABLE** statement.

Most importantly, you should remember that the new partitioning scheme cannot have any overlapping ranges (applies to tables partitioned by **RANGE**) or sets of values (when reorganizing tables partitioned by **LIST**).

Note: Prior to MySQL 5.1.4, you could not reuse the names of existing partitions in the **INTO** clause, even when those partitions were being dropped or redefined. See [Section D.1.9, “Changes in release 5.1.4 \(21 December 2005\)”](#), for more information.

- The combination of partitions in the *partition_definitions* list should account for the same range or set of values overall as the combined partitions named in the *partition_list*.

For instance, in the *members* table used as an example in this section, partitions **p1** and **p2** together cover the years 1980 through 1999. Therefore, any reorganization of these two partitions should cover the same range of years overall.

- For tables partitioned by **RANGE**, you can reorganize only adjacent partitions; you cannot skip over range partitions.

For instance, you could not reorganize the *members* table used as an example in this section using a statement beginning with **ALTER TABLE members REORGANIZE PARTITION p0,p2 INTO ...** because **p0** covers the years prior to 1970 and **p2** the years from 1990 through 1999 inclusive, and thus the two are not adjacent partitions.

- You cannot use **REORGANIZE PARTITION** to change the table's partitioning type; that is, you cannot (for example) change **RANGE** partitions to **HASH** partitions or *vice versa*. You also cannot use this command to change the partitioning expression or column. To accomplish either of these tasks without dropping and re-creating the table, you can use **ALTER TABLE ... PARTITION BY ...** For example:

```
ALTER TABLE members
PARTITION BY HASH( YEAR(dob) )
PARTITIONS 8;
```

16.3.2. Management of **HASH** and **KEY** Partitions

Tables which are partitioned by hash or by key are very similar to one another with regard to making changes in a partitioning setup, and both differ in a number of ways from tables which have been partitioned by range or list. For that reason, this section addresses the modification of tables partitioned by hash or by key only. For a discussion of adding and dropping of partitions of tables that are partitioned by range or list, see [Section 16.3.1, “Management of RANGE and LIST Partitions”](#).

You cannot drop partitions from tables that are partitioned by **HASH** or **KEY** in the same way that you can from tables that are partitioned by **RANGE** or **LIST**. However, you can merge **HASH** or **KEY** partitions using the **ALTER TABLE ... COALESCE PARTITION** command. For example, suppose that you have a table containing data about clients, which is divided into twelve partitions. The *clients* table is defined as shown here:

```
CREATE TABLE clients (
  id INT,
  fname VARCHAR(30),
  lname VARCHAR(30),
  signed DATE
)
PARTITION BY HASH( MONTH(signed) )
PARTITIONS 12;
```

To reduce the number of partitions from twelve to eight, execute the following `ALTER TABLE` command:

```
mysql> ALTER TABLE clients COALESCE PARTITION 4;
Query OK, 0 rows affected (0.02 sec)
```

`COALESCE` works equally well with tables that are partitioned by `HASH`, `KEY`, `LINEAR HASH`, or `LINEAR KEY`. Here is an example similar to the previous one, differing only in that the table is partitioned by `LINEAR KEY`:

```
mysql> CREATE TABLE clients_lk (
->   id INT,
->   fname VARCHAR(30),
->   lname VARCHAR(30),
->   signed DATE
-> )
-> PARTITION BY LINEAR KEY(signed)
-> PARTITIONS 12;
Query OK, 0 rows affected (0.03 sec)

mysql> ALTER TABLE clients_lk COALESCE PARTITION 4;
Query OK, 0 rows affected (0.06 sec)
Records: 0 Duplicates: 0 Warnings: 0
```

Note that the number following `COALESCE PARTITION` is the number of partitions to merge into the remainder — in other words, it is the number of partitions to remove from the table.

If you attempt to remove more partitions than the table has, the result is an error like the one shown:

```
mysql> ALTER TABLE clients COALESCE PARTITION 18;
ERROR 1478 (HY000): Cannot remove all partitions, use DROP TABLE instead
```

To increase the number of partitions for the `clients` table from 12 to 18, use `ALTER TABLE ... ADD PARTITION` as shown here:

```
ALTER TABLE clients ADD PARTITION PARTITIONS 6;
```

16.3.3. Maintenance of Partitions

A number of partitioning maintenance tasks can be carried out in MySQL 5.1. MySQL does not support the commands `CHECK TABLE`, `OPTIMIZE TABLE`, `ANALYZE TABLE`, or `REPAIR TABLE` for partitioned tables. Instead, you can use a number of extensions to `ALTER TABLE` which were implemented in MySQL 5.1.5. These can be used for performing operations of this type on one or more partitions directly, as described in the following list:

- **Rebuilding partitions:** Rebuilds the partition; this has the same effect as dropping all records stored in the partition, then reinserting them. This can be useful for purposes of defragmentation.

Example:

```
ALTER TABLE t1 REBUILD PARTITION p0, p1;
```

- **Optimizing partitions:** If you have deleted a large number of rows from a partition or if you have made many changes to a partitioned table with variable-length rows (that is, having `VARCHAR`, `BLOB`, or `TEXT` columns), you can use `ALTER TABLE ... OPTIMIZE PARTITION` to reclaim any unused space and to defragment the partition data file.

Example:

```
ALTER TABLE t1 OPTIMIZE PARTITION p0, p1;
```

Using `OPTIMIZE PARTITION` on a given partition is equivalent to running `CHECK PARTITION`, `ANALYZE PARTITION`, and `REPAIR PARTITION` on that partition.

- **Analyzing partitions:** This reads and stores the key distributions for partitions.

Example:

```
ALTER TABLE t1 ANALYZE PARTITION p3;
```

- **Repairing partitions:** This repairs corrupted partitions.

Example:

```
ALTER TABLE t1 REPAIR PARTITION p0,p1;
```

- **Checking partitions:** You can check partitions for errors in much the same way that you can use `CHECK TABLE` with non-partitioned tables.

Example:

```
ALTER TABLE trb3 CHECK PARTITION p1;
```

This command will tell you if the data or indexes in partition `p1` of table `t1` are corrupted. If this is the case, use `ALTER TABLE ... REPAIR PARTITION` to repair the partition.

You can also use the `mysqlcheck` or `myisamchk` utility to accomplish these tasks, operating on the separate `.MYI` files generated by partitioning a table. See [Section 8.10, “mysqlcheck — A Table Maintenance and Repair Program”](#).

16.3.4. Obtaining Information About Partitions

This section discusses obtaining information about existing partitions, which can be done in a number of ways. These include:

- Using the `SHOW CREATE TABLE` statement to view the partitioning clauses used in creating a partitioned table.
- Using the `SHOW TABLE STATUS` statement to determine whether a table is partitioned.
- Querying the `INFORMATION_SCHEMA.PARTITIONS` table.
- Using the statement `EXPLAIN PARTITIONS SELECT` to see which partitions are used by a given `SELECT`.

As discussed elsewhere in this chapter, `SHOW CREATE TABLE` includes in its output the `PARTITION BY` clause used to create a partitioned table. For example:

```
mysql> SHOW CREATE TABLE trb3\G
***** 1. row *****
      Table: trb3
Create Table: CREATE TABLE `trb3` (
```

```

`id` int(11) default NULL,
`name` varchar(50) default NULL,
`purchased` date default NULL
) ENGINE=MyISAM DEFAULT CHARSET=latin1
PARTITION BY RANGE (YEAR(purchased)) (
PARTITION p0 VALUES LESS THAN (1990) ENGINE = MyISAM,
PARTITION p1 VALUES LESS THAN (1995) ENGINE = MyISAM,
PARTITION p2 VALUES LESS THAN (2000) ENGINE = MyISAM,
PARTITION p3 VALUES LESS THAN (2005) ENGINE = MyISAM
)
1 row in set (0.00 sec)

```

Note: In early MySQL 5.1 releases, the `PARTITIONS` clause was not shown for tables partitioned by `HASH` or `KEY`. This issue was fixed in MySQL 5.1.6.

`SHOW TABLE STATUS` works with partitioned tables. Beginning with MySQL 5.1.9, its output is the same as that for non-partitioned tables, except that the `Create_options` column contains the string `partitioned`. In MySQL 5.1.8 and earlier, the `Engine` column always contained the value `PARTITION`; beginning with MySQL 5.1.9, this column contains the name of the storage engine used by all partitions of the table. (See [Section 13.5.4.26](#), “`SHOW TABLE STATUS Syntax`”, for more information about this command.)

You can also obtain information about partitions from `INFORMATION_SCHEMA`, which contains a `PARTITIONS` table. See [Section 22.19](#), “`The INFORMATION_SCHEMA PARTITIONS Table`”.

Beginning with MySQL 5.1.5, it is possible to determine which partitions of a partitioned table are involved in a given `SELECT` query using `EXPLAIN PARTITIONS`. The `PARTITIONS` keyword adds a `partitions` column to the output of `EXPLAIN` listing the partitions from which records would be matched by the query.

Suppose that you have a table `trb1` defined and populated as follows:

```

CREATE TABLE trb1 (id INT, name VARCHAR(50), purchased DATE)
PARTITION BY RANGE(id)
(
PARTITION p0 VALUES LESS THAN (3),
PARTITION p1 VALUES LESS THAN (7),
PARTITION p2 VALUES LESS THAN (9),
PARTITION p3 VALUES LESS THAN (11)
);

INSERT INTO trb1 VALUES
(1, 'desk organiser', '2003-10-15'),
(2, 'CD player', '1993-11-05'),
(3, 'TV set', '1996-03-10'),
(4, 'bookcase', '1982-01-10'),
(5, 'exercise bike', '2004-05-09'),
(6, 'sofa', '1987-06-05'),
(7, 'popcorn maker', '2001-11-22'),
(8, 'aquarium', '1992-08-04'),
(9, 'study desk', '1984-09-16'),
(10, 'lava lamp', '1998-12-25');

```

You can see which partitions are used in a query such as `SELECT * FROM trb1;`, as shown here:

```

mysql> EXPLAIN PARTITIONS SELECT * FROM trb1\G
***** 1. row *****
id: 1
select_type: SIMPLE
table: trb1
partitions: p0,p1,p2,p3
type: ALL
possible_keys: NULL
key: NULL
key_len: NULL
ref: NULL
rows: 10
Extra: Using filesort

```

In this case, all four partitions are searched. However, when a limiting condition making use of the partitioning key is added to the query, you can see that only those partitions containing matching values are scanned, as shown here:

```
mysql> EXPLAIN PARTITIONS SELECT * FROM trb1 WHERE id < 5\G
***** 1. row *****
      id: 1
  select_type: SIMPLE
        table: trb1
  partitions: p0,p1
         type: ALL
possible_keys: NULL
         key: NULL
      key_len: NULL
         ref: NULL
         rows: 10
      Extra: Using where
```

`EXPLAIN PARTITIONS` provides information about keys used and possible keys, just as with the standard `EXPLAIN SELECT` statement:

```
mysql> ALTER TABLE trb1 ADD PRIMARY KEY (id);
Query OK, 10 rows affected (0.03 sec)
Records: 10 Duplicates: 0 Warnings: 0

mysql> EXPLAIN PARTITIONS SELECT * FROM trb1 WHERE id < 5\G
***** 1. row *****
      id: 1
  select_type: SIMPLE
        table: trb1
  partitions: p0,p1
         type: range
possible_keys: PRIMARY
         key: PRIMARY
      key_len: 4
         ref: NULL
         rows: 7
      Extra: Using where
```

You should take note of the following restrictions and limitations on `EXPLAIN PARTITIONS`:

- You cannot use the `PARTITIONS` and `EXTENDED` keywords together in the same `EXPLAIN ... SELECT` statement. Attempting to do so produces a syntax error.
- If `EXPLAIN PARTITIONS` is used to examine a query against a non-partitioned table, no error is produced, but the value of the `partitions` column is always `NULL`.

See also [Section 7.2.1, “Optimizing Queries with EXPLAIN”](#).

16.4. Partition Pruning

This section discusses *partition pruning*, an optimisation which was implemented for partitioned tables in MySQL 5.1.6.

The core concept behind partition pruning is relatively simple, and can be described as “Do not scan partitions where there can be no matching values”. For example, suppose you have a partitioned table `t1` defined by this statement:

```
CREATE TABLE t1 (
  fname VARCHAR(50) NOT NULL,
  lname VARCHAR(50) NOT NULL,
  region_code TINYINT UNSIGNED NOT NULL,
  dob DATE NOT NULL
)
PARTITION BY RANGE( region_code ) (
```

```

PARTITION p0 VALUES LESS THAN (64),
PARTITION p1 VALUES LESS THAN (128),
PARTITION p2 VALUES LESS THAN (192)
PARTITION p3 VALUES LESS THAN MAXVALUE
);

```

Consider the case where you wish to obtain results from a query such as this one:

```

SELECT fname, lname, postcode, dob
FROM t1
WHERE region_code > 125 AND region_code < 130;

```

It is easy to see that none of the rows which ought to be returned will be in either of the partitions `p0` or `p3`; that is, we need to search only in partitions `p1` and `p2` to find matching rows. By doing so, it is possible to expend much more time and effort in finding matching rows than it is to scan all partitions in the table. This “cutting away” of unneeded partitions is known as *pruning*. When the optimiser can make use of partition pruning in performing a query, execution of the query can be an order of magnitude faster than the same query against a non-partitioned table containing the same column definitions and data.

The query optimiser can perform pruning whenever a `WHERE` condition can be reduced to either one of the following:

- `partition_column = constant`
- `partition_column IN (constant1, constant2, ..., constantN)`

In the first case, the optimizer simply evaluates the partitioning expression for the value given, determines which partition contains that value, and scans only this partition. In the second case, the optimizer evaluates the partitioning expression for each value in the list, creates a list of matching partitions, and then scans only the partitions in this partition list.

Pruning can also be applied to short ranges, which the optimizer can convert into equivalent lists of values. For instance, in the previous example, the `WHERE` clause can be converted to `WHERE region_code IN (125, 126, 127, 128, 129, 130)`. Then the optimizer can determine that the first three values in the list are found in partition `p1`, the remaining three values in partition `p2`, and that the other partitions contain no relevant values and so do not need to be searched for matching rows.

This type of optimization can be applied whenever the partitioning expression consists of an equality or a range which can be reduced to a set of equalities. It can also be employed when the partitioning expression represents an increasing or decreasing relationship or uses a function such as `YEAR()` or `TO_DAYS()` that produces an integer value when applied to a `DATE` or `DATETIME` column value. For example, suppose that table `t2`, defined as shown here, is partitioned on a `DATE` column:

```

CREATE TABLE t2 (
  fname VARCHAR(50) NOT NULL,
  lname VARCHAR(50) NOT NULL,
  region_code TINYINT UNSIGNED NOT NULL,
  dob DATE NOT NULL
)
PARTITION BY RANGE( YEAR(dob) ) (
  PARTITION d0 VALUES LESS THAN (1970),
  PARTITION d1 VALUES LESS THAN (1975),
  PARTITION d2 VALUES LESS THAN (1980),
  PARTITION d3 VALUES LESS THAN (1985),
  PARTITION d4 VALUES LESS THAN (1990),
  PARTITION d5 VALUES LESS THAN (2000),
  PARTITION d6 VALUES LESS THAN (2005),
  PARTITION d7 VALUES LESS THAN MAXVALUE
);

```

The following queries on `t2` can make use of partition pruning:

```
SELECT * FROM t2 WHERE dob = '1982-06-23';
SELECT * FROM t2 WHERE dob BETWEEN '1991-02-15' AND '1997-04-25';
SELECT * FROM t2 WHERE YEAR(dob)
    IN (1979, 1980, 1983, 1985, 1986, 1988);
SELECT * FROM t2 WHERE dob >= '1984-06-21' AND dob <= '1999-06-21'
```

In the case of the last query, the optimizer can also act as follows:

1. Find the partition containing the low end of the range.
`YEAR('1984-06-21')` yields the value `1984`, which is found in partition `d3`.
2. Find the partition containing the high end of the range.
`YEAR('1999-06-21')` evaluates to `1999`, which is found in partition `d5`.
3. Scan only these two partitions and any partitions that may lie between them.

In this case, this means that only partitions `d3`, `d4`, and `d5` are scanned. The remaining partitions may be safely ignored (and are ignored).

So far, we have looked only at examples using `RANGE` partitioning, but pruning can be applied with other partitioning types as well.

Consider a table that is partitioned by `LIST`, where the partitioning expression is increasing or decreasing, such as the table `t3` shown here. (In this example, we assume for the sake of brevity that the `region_code` column is limited to values between 1 and 10 inclusive.)

```
CREATE TABLE t3 (
    fname VARCHAR(50) NOT NULL,
    lname VARCHAR(50) NOT NULL,
    region_code TINYINT UNSIGNED NOT NULL,
    dob DATE NOT NULL
)
PARTITION BY LIST(region_code) (
    PARTITION r0 VALUES IN (1, 3),
    PARTITION r1 VALUES IN (2, 5, 8),
    PARTITION r2 VALUES IN (4, 9),
    PARTITION r3 VALUES IN (6, 7, 10)
);
```

For a query such as `SELECT * FROM t3 WHERE region_code BETWEEN 1 AND 3`, the optimizer determines in which partitions the values 1, 2, and 3 are found (`r0` and `r1`) and skips the remaining ones (`r2` and `r3`).

For tables that are partitioned by `HASH` or `KEY`, partition pruning is also possible in cases in which the `WHERE` clause uses a simple `=` relation against a column used in the partitioning expression. Consider a table created like this:

```
CREATE TABLE t4 (
    fname VARCHAR(50) NOT NULL,
    lname VARCHAR(50) NOT NULL,
    region_code TINYINT UNSIGNED NOT NULL,
    dob DATE NOT NULL
)
PARTITION BY KEY(region_code)
PARTITIONS 8;
```

Any query such as this one can be pruned:

```
SELECT * FROM t4 WHERE region_code = 7;
```

Pruning can also be employed for short ranges, because the optimizer can turn such conditions into `IN` relations. For example, using the same table `t4` as defined previously, queries such as these can be pruned:

```
SELECT * FROM t4 WHERE region_code > 2 AND region_code < 6;
SELECT * FROM t4 WHERE region_code BETWEEN 3 AND 5;
```

In both these cases, the `WHERE` clause is transformed by the optimizer into `WHERE region_code IN (3, 4, 5)`. **Important:** This optimization is used only if the range size is smaller than the number of partitions. Consider this query:

```
SELECT * FROM t4 WHERE region_code BETWEEN 4 AND 8;
```

The range in the `WHERE` clause covers 5 values (4, 5, 6, 7, 8), but `t4` has only 4 partitions. This means that the previous query cannot be pruned.

Pruning can be used only on integer columns of tables partitioned by `HASH` or `KEY`. For example, this query on table `t4` cannot use pruning because `dob` is a `DATE` column:

```
SELECT * FROM t4 WHERE dob >= '2001-04-14' AND dob <= '2005-10-15';
```

However, if the table stores year values in an `INT` column, then a query having `WHERE year_col >= 2001 AND year_col <= 2005` can be pruned.

16.5. Restrictions and Limitations on Partitioning

This section discusses current restrictions and limitations on MySQL partitioning support, as listed here:

- If, when creating tables with a very large number of partitions, you encounter an error message such as Got error 24 from storage engine, you may need to increase the value of the `open_files_limit` system variable. See [Section A.2.17, “File Not Found”](#).
- Partitioned tables do not support foreign keys. This includes partitioned tables employing the `InnoDB` storage engine.
- Partitioned tables do not support `FULLTEXT` indexes. This includes partitioned tables employing the `MyISAM` storage engine.
- Partitioned tables do not support `GEOMETRY` columns.
- As of MySQL 5.1.8, temporary tables cannot be partitioned. ([Bug#17497](#) [<http://bugs.mysql.com/17497>])
- Tables using the `MERGE` storage engine cannot be partitioned.

Partitioned tables using the `CSV` storage engine are not supported. Starting with MySQL 5.1.12, it is not possible to create partitioned `CSV` tables at all.

Prior to MySQL 5.1.6, tables using the `BLACKHOLE` storage engine also could not be partitioned.

Partitioning by [KEY](#) (or [LINEAR KEY](#)) is the only type of partitioning supported for the [NDB](#) storage engine. Beginning with MySQL 5.1.12, it is not possible to create a Cluster table using any partitioning type other than [\[LINEAR\] KEY](#), and attempting to do so gives rise to an error.

- When performing an upgrade, tables using any storage engine other than [NDBCLUSTER](#) and which are partitioned by [KEY](#) must be dumped and reloaded.
- All of a table's partitions and subpartitions (if there are any of the latter) must use the same storage engine.
- A partitioning key must be either an integer column or an expression that resolves to an integer. The column or expression value may also be [NULL](#). (See [Section 16.2.6, “How MySQL Partitioning Handles NULL Values”](#).)

The one exception to this restriction occurs when partitioning by [\[LINEAR\] KEY](#) — where it is possible to use columns of other types as partitioning keys — because MySQL's internal key-hashing functions produce the correct datatype from these types. For example, the following [CREATE TABLE](#) statement is valid:

```
CREATE TABLE tkc (c1 CHAR)
PARTITION BY KEY(c1)
PARTITIONS 4;
```

This exception does *not* apply to [BLOB](#) or [TEXT](#) column types.

- A partitioning key may not be a subquery, even if that subquery resolves to an integer value or [NULL](#).
- All columns used in the partitioning expression for a partitioned table must be part of every unique key that the table may have. In other words, every unique key on the table must use every column in the table's partitioning expression. For example, each of the following table creation statements is invalid:

```
CREATE TABLE t1 (
  col1 INT NOT NULL,
  col2 DATE NOT NULL,
  col3 INT NOT NULL,
  col4 INT NOT NULL,
  UNIQUE KEY (col1, col2)
)
PARTITION BY HASH(col3)
PARTITIONS 4;

CREATE TABLE t2 (
  col1 INT NOT NULL,
  col2 DATE NOT NULL,
  col3 INT NOT NULL,
  col4 INT NOT NULL,
  UNIQUE KEY (col1),
  UNIQUE KEY (col3)
)
PARTITION BY HASH(col1 + col3)
PARTITIONS 4;

CREATE TABLE t3 (
  col1 INT NOT NULL,
  col2 DATE NOT NULL,
  col3 INT NOT NULL,
  col4 INT NOT NULL,
  UNIQUE KEY (col1, col2),
  UNIQUE KEY (col3)
)
PARTITION BY HASH(col1 + col3)
PARTITIONS 4;
```

In each case, the proposed table would have at least one unique key that does not include all columns used in the partitioning expression.

Each of the following statements is valid, and represents one way in which the corresponding invalid table creation statement could be made to work:

```
CREATE TABLE t1 (
  col1 INT NOT NULL,
  col2 DATE NOT NULL,
  col3 INT NOT NULL,
  col4 INT NOT NULL,
  UNIQUE KEY (col1, col2, col3)
)
PARTITION BY HASH(col3)
PARTITIONS 4;

CREATE TABLE t2 (
  col1 INT NOT NULL,
  col2 DATE NOT NULL,
  col3 INT NOT NULL,
  col4 INT NOT NULL,
  UNIQUE KEY (col1, col3)
)
PARTITION BY HASH(col1 + col3)
PARTITIONS 4;

CREATE TABLE t3 (
  col1 INT NOT NULL,
  col2 DATE NOT NULL,
  col3 INT NOT NULL,
  col4 INT NOT NULL,
  UNIQUE KEY (col1, col2, col3),
  UNIQUE KEY (col3)
)
PARTITION BY HASH(col3)
PARTITIONS 4;
```

Since every primary key is by definition a unique key, this restriction also includes the table's primary key, if it has one. For example, the next two statements are invalid:

```
CREATE TABLE t4 (
  col1 INT NOT NULL,
  col2 DATE NOT NULL,
  col3 INT NOT NULL,
  col4 INT NOT NULL,
  PRIMARY KEY(col1, col2)
)
PARTITION BY HASH(col3)
PARTITIONS 4;

CREATE TABLE t5 (
  col1 INT NOT NULL,
  col2 DATE NOT NULL,
  col3 INT NOT NULL,
  col4 INT NOT NULL,
  PRIMARY KEY(col1, col3),
  UNIQUE KEY(col2)
)
PARTITION BY HASH( YEAR(col2) )
PARTITIONS 4;
```

In both cases, the primary key does not include all columns referenced in the partitioning expression. However, both of the next two statements are valid:

```
CREATE TABLE t6 (
  col1 INT NOT NULL,
  col2 DATE NOT NULL,
  col3 INT NOT NULL,
  col4 INT NOT NULL,
  PRIMARY KEY(col1, col2)
)
PARTITION BY HASH(col1 + YEAR(col2))
```

```
PARTITIONS 4;

CREATE TABLE t7 (
  col1 INT NOT NULL,
  col2 DATE NOT NULL,
  col3 INT NOT NULL,
  col4 INT NOT NULL,
  PRIMARY KEY(col1, col2, col4),
  UNIQUE KEY(col2, col1)
)
PARTITION BY HASH(col1 + YEAR(col2))
PARTITIONS 4;
```

If a table has no unique keys — this includes having no primary key — then this restriction does not apply, and you may use any column or columns in the partitioning expression as long as the column type is compatible with the partitioning type.

For the same reason, you cannot later add a unique key to a partitioned table unless the key includes all columns used by the table's partitioning expression. Consider given the partitioned table defined as shown here:

```
CREATE TABLE t_no_pk (c1 INT, c2 INT)
PARTITION BY RANGE(c1) (
  PARTITION p0 VALUES LESS THAN (10),
  PARTITION p1 VALUES LESS THAN (20),
  PARTITION p2 VALUES LESS THAN (30),
  PARTITION p3 VALUES LESS THAN (40)
);
```

It is possible to add a primary key to `t_no_pk` using either of these `ALTER TABLE` statements:

```
# possible PK
ALTER TABLE t_no_pk ADD PRIMARY KEY(c1);

# also a possible PK
ALTER TABLE t_no_pk ADD PRIMARY KEY(c1, c2);
```

However, the next statement fails, because `c1` is part of the partitioning key, but is not part of the proposed primary key:

```
# fails with ERROR 1482
ALTER TABLE t_no_pk ADD PRIMARY KEY(c2);
```

Since `t_no_pk` has only `c1` in its partitioning expression, attempting to adding a unique key on `c2` alone fails. However, you can add a unique key that uses both `c1` and `c2`.

These rules also apply to existing non-partitioned tables that you wish to partition using `ALTER TABLE ... PARTITION BY`. Consider a table `np_pk` defined as shown here:

```
CREATE TABLE np_pk (
  id INT NOT NULL AUTO_INCREMENT,
  name VARCHAR(50),
  added DATE,
  PRIMARY KEY (id)
);
```

The following `ALTER TABLE` statements fails with an error, because the `added` column is not part of any unique key in the table:

```
ALTER TABLE np_pk
PARTITION BY HASH( TO_DAYS(added) )
PARTITIONS 4;
```

This statement, however, would be valid:

```
ALTER TABLE np_pk
  PARTITION BY HASH(id)
  PARTITIONS 4;
```

In the case of `np_pk`, the only column that may be used as part of a partitioning expression is `id`; if you wish to partition this table using any other column or columns in the partitioning expression, you must first modify the table, either by adding the desired column or columns to the primary key, or by dropping the primary key altogether.

We are working to remove this limitation in a future MySQL release series.

- Subpartitions are limited to `HASH` or `KEY` partitioning. `HASH` and `KEY` partitions cannot be subpartitioned.

Chapter 17. Spatial Extensions

MySQL supports spatial extensions to allow the generation, storage, and analysis of geographic features. These features are available for [MyISAM](#), [InnoDB](#), [NDB](#), and [ARCHIVE](#) tables. (However, the [ARCHIVE](#) engine does not support indexing, so spatial columns in [ARCHIVE](#) columns cannot be indexed. MySQL Cluster also does not support indexing of spatial columns.)

Although spatial extensions are supported in [InnoDB](#) tables, use of spatial indexes may cause a crash. ([Bug#15860](#) [<http://bugs.mysql.com/15860>])

This chapter covers the following topics:

- The basis of these spatial extensions in the OpenGIS geometry model
- Data formats for representing spatial data
- How to use spatial data in MySQL
- Use of indexing for spatial data
- MySQL differences from the OpenGIS specification

Additional resources

- The Open Geospatial Consortium publishes the *OpenGIS® Simple Features Specifications For SQL*, a document that proposes several conceptual ways for extending an SQL RDBMS to support spatial data. This specification is available from the OGC Web site at <http://www.opengis.org/docs/99-049.pdf>.
- If you have questions or concerns about the use of the spatial extensions to MySQL, you can discuss them in the GIS forum: <http://forums.mysql.com/list.php?23>.

17.1. Introduction to MySQL Spatial Support

MySQL implements spatial extensions following the specification of the Open Geospatial Consortium (OGC). This is an international consortium of more than 250 companies, agencies, and universities participating in the development of publicly available conceptual solutions that can be useful with all kinds of applications that manage spatial data. The OGC maintains a Web site at <http://www.opengis.org/>.

In 1997, the Open Geospatial Consortium published the *OpenGIS® Simple Features Specifications For SQL*, a document that proposes several conceptual ways for extending an SQL RDBMS to support spatial data. This specification is available from the OGC Web site at <http://www.opengis.org/docs/99-049.pdf>. It contains additional information relevant to this chapter.

MySQL implements a subset of the **SQL with Geometry Types** environment proposed by OGC. This term refers to an SQL environment that has been extended with a set of geometry types. A geometry-valued SQL column is implemented as a column that has a geometry type. The specification describe a set of SQL geometry types, as well as functions on those types to create and analyze geometry values.

A **geographic feature** is anything in the world that has a location. A feature can be:

- An entity. For example, a mountain, a pond, a city.

- A space. For example, a postcode area, the tropics.
- A definable location. For example, a crossroad, as a particular place where two streets intersect.

Some documents use the term **geospatial feature** to refer to geographic features.

Geometry is another word that denotes a geographic feature. Originally the word **geometry** meant measurement of the earth. Another meaning comes from cartography, referring to the geometric features that cartographers use to map the world.

This chapter uses all of these terms synonymously: **geographic feature**, **geospatial feature**, **feature**, or **geometry**. Here, the term most commonly used is **geometry**, defined as *a point or an aggregate of points representing anything in the world that has a location*.

17.2. The OpenGIS Geometry Model

The set of geometry types proposed by OGC's **SQL with Geometry Types** environment is based on the **OpenGIS Geometry Model**. In this model, each geometric object has the following general properties:

- It is associated with a Spatial Reference System, which describes the coordinate space in which the object is defined.
- It belongs to some geometry class.

17.2.1. The Geometry Class Hierarchy

The geometry classes define a hierarchy as follows:

- `Geometry` (non-instantiable)
 - `Point` (instantiable)
 - `Curve` (non-instantiable)
 - `LineString` (instantiable)
 - `Line`
 - `LinearRing`
 - `Surface` (non-instantiable)
 - `Polygon` (instantiable)
 - `GeometryCollection` (instantiable)
 - `MultiPoint` (instantiable)
 - `MultiCurve` (non-instantiable)
 - `MultiLineString` (instantiable)
 - `MultiSurface` (non-instantiable)

- `MultiPolygon` (instantiateable)

It is not possible to create objects in non-instantiateable classes. It is possible to create objects in instantiateable classes. All classes have properties, and instantiateable classes may also have assertions (rules that define valid class instances).

`Geometry` is the base class. It is an abstract class. The instantiateable subclasses of `Geometry` are restricted to zero-, one-, and two-dimensional geometric objects that exist in two-dimensional coordinate space. All instantiateable geometry classes are defined so that valid instances of a geometry class are topologically closed (that is, all defined geometries include their boundary).

The base `Geometry` class has subclasses for `Point`, `Curve`, `Surface`, and `GeometryCollection`:

- `Point` represents zero-dimensional objects.
- `Curve` represents one-dimensional objects, and has subclass `LineString`, with sub-subclasses `Line` and `LinearRing`.
- `Surface` is designed for two-dimensional objects and has subclass `Polygon`.
- `GeometryCollection` has specialized zero-, one-, and two-dimensional collection classes named `MultiPoint`, `MultiLineString`, and `MultiPolygon` for modeling geometries corresponding to collections of `Points`, `LineStrings`, and `Polygons`, respectively. `MultiCurve` and `MultiSurface` are introduced as abstract superclasses that generalize the collection interfaces to handle `Curves` and `Surfaces`.

`Geometry`, `Curve`, `Surface`, `MultiCurve`, and `MultiSurface` are defined as non-instantiateable classes. They define a common set of methods for their subclasses and are included for extensibility.

`Point`, `LineString`, `Polygon`, `GeometryCollection`, `MultiPoint`, `MultiLineString`, and `MultiPolygon` are instantiateable classes.

17.2.2. Class `Geometry`

`Geometry` is the root class of the hierarchy. It is a non-instantiateable class but has a number of properties that are common to all geometry values created from any of the `Geometry` subclasses. These properties are described in the following list. Particular subclasses have their own specific properties, described later.

Geometry Properties

A geometry value has the following properties:

- Its **type**. Each geometry belongs to one of the instantiateable classes in the hierarchy.
- Its **SRID**, or Spatial Reference Identifier. This value identifies the geometry's associated Spatial Reference System that describes the coordinate space in which the geometry object is defined.

In MySQL, the SRID value is just an integer associated with the geometry value. All calculations are done assuming Euclidean (planar) geometry.

- Its **coordinates** in its Spatial Reference System, represented as double-precision (eight-byte) numbers. All non-empty geometries include at least one pair of (X,Y) coordinates. Empty geometries contain no coordinates.

Coordinates are related to the SRID. For example, in different coordinate systems, the distance between two objects may differ even when objects have the same coordinates, because the distance on the **planar** coordinate system and the distance on the **geocentric** system (coordinates on the Earth's surface) are different things.

- Its **interior**, **boundary**, and **exterior**.

Every geometry occupies some position in space. The exterior of a geometry is all space not occupied by the geometry. The interior is the space occupied by the geometry. The boundary is the interface between the geometry's interior and exterior.

- Its **MBR** (Minimum Bounding Rectangle), or Envelope. This is the bounding geometry, formed by the minimum and maximum (X,Y) coordinates:

```
((MINX MINY, MAXX MINY, MAXX MAXY, MINX MAXY, MINX MINY))
```

- Whether the value is **simple** or **non-simple**. Geometry values of types ([LineString](#), [MultiPoint](#), [MultiLineString](#)) are either simple or non-simple. Each type determines its own assertions for being simple or non-simple.
- Whether the value is **closed** or **not closed**. Geometry values of types ([LineString](#), [MultiString](#)) are either closed or not closed. Each type determines its own assertions for being closed or not closed.
- Whether the value is **empty** or **non-empty**. A geometry is empty if it does not have any points. Exterior, interior, and boundary of an empty geometry are not defined (that is, they are represented by a [NULL](#) value). An empty geometry is defined to be always simple and has an area of 0.
- Its **dimension**. A geometry can have a dimension of -1, 0, 1, or 2:
 - -1 for an empty geometry.
 - 0 for a geometry with no length and no area.
 - 1 for a geometry with non-zero length and zero area.
 - 2 for a geometry with non-zero area.

[Point](#) objects have a dimension of zero. [LineString](#) objects have a dimension of 1. [Polygon](#) objects have a dimension of 2. The dimensions of [MultiPoint](#), [MultiLineString](#), and [MultiPolygon](#) objects are the same as the dimensions of the elements they consist of.

17.2.3. Class [Point](#)

A [Point](#) is a geometry that represents a single location in coordinate space.

[Point](#) Examples

- Imagine a large-scale map of the world with many cities. A [Point](#) object could represent each city.
- On a city map, a [Point](#) object could represent a bus stop.

Point Properties

- X-coordinate value.
- Y-coordinate value.
- `Point` is defined as a zero-dimensional geometry.
- The boundary of a `Point` is the empty set.

17.2.4. Class `Curve`

A `Curve` is a one-dimensional geometry, usually represented by a sequence of points. Particular subclasses of `Curve` define the type of interpolation between points. `Curve` is a non-instantiable class.

Curve Properties

- A `Curve` has the coordinates of its points.
- A `Curve` is defined as a one-dimensional geometry.
- A `Curve` is simple if it does not pass through the same point twice.
- A `Curve` is closed if its start point is equal to its endpoint.
- The boundary of a closed `Curve` is empty.
- The boundary of a non-closed `Curve` consists of its two endpoints.
- A `Curve` that is simple and closed is a `LinearRing`.

17.2.5. Class `LineString`

A `LineString` is a `Curve` with linear interpolation between points.

LineString Examples

- On a world map, `LineString` objects could represent rivers.
- In a city map, `LineString` objects could represent streets.

LineString Properties

- A `LineString` has coordinates of segments, defined by each consecutive pair of points.
- A `LineString` is a `Line` if it consists of exactly two points.
- A `LineString` is a `LinearRing` if it is both closed and simple.

17.2.6. Class `Surface`

A [Surface](#) is a two-dimensional geometry. It is a non-instantiable class. Its only instantiable subclass is [Polygon](#).

Surface Properties

- A [Surface](#) is defined as a two-dimensional geometry.
- The OpenGIS specification defines a simple [Surface](#) as a geometry that consists of a single “patch” that is associated with a single exterior boundary and zero or more interior boundaries.
- The boundary of a simple [Surface](#) is the set of closed curves corresponding to its exterior and interior boundaries.

17.2.7. Class [Polygon](#)

A [Polygon](#) is a planar [Surface](#) representing a multisided geometry. It is defined by a single exterior boundary and zero or more interior boundaries, where each interior boundary defines a hole in the [Polygon](#).

Polygon Examples

- On a region map, [Polygon](#) objects could represent forests, districts, and so on.

Polygon Assertions

- The boundary of a [Polygon](#) consists of a set of [LinearRing](#) objects (that is, [LineString](#) objects that are both simple and closed) that make up its exterior and interior boundaries.
- A [Polygon](#) has no rings that cross. The rings in the boundary of a [Polygon](#) may intersect at a [Point](#), but only as a tangent.
- A [Polygon](#) has no lines, spikes, or punctures.
- A [Polygon](#) has an interior that is a connected point set.
- A [Polygon](#) may have holes. The exterior of a [Polygon](#) with holes is not connected. Each hole defines a connected component of the exterior.

The preceding assertions make a [Polygon](#) a simple geometry.

17.2.8. Class [GeometryCollection](#)

A [GeometryCollection](#) is a geometry that is a collection of one or more geometries of any class.

All the elements in a [GeometryCollection](#) must be in the same Spatial Reference System (that is, in the same coordinate system). There are no other constraints on the elements of a [GeometryCollection](#), although the subclasses of [GeometryCollection](#) described in the following sections may restrict membership. Restrictions may be based on:

- Element type (for example, a [MultiPoint](#) may contain only [Point](#) elements)
- Dimension

- Constraints on the degree of spatial overlap between elements

17.2.9. Class `MultiPoint`

A `MultiPoint` is a geometry collection composed of `Point` elements. The points are not connected or ordered in any way.

`MultiPoint` Examples

- On a world map, a `MultiPoint` could represent a chain of small islands.
- On a city map, a `MultiPoint` could represent the outlets for a ticket office.

`MultiPoint` Properties

- A `MultiPoint` is a zero-dimensional geometry.
- A `MultiPoint` is simple if no two of its `Point` values are equal (have identical coordinate values).
- The boundary of a `MultiPoint` is the empty set.

17.2.10. Class `MultiCurve`

A `MultiCurve` is a geometry collection composed of `Curve` elements. `MultiCurve` is a non-instantiable class.

`MultiCurve` Properties

- A `MultiCurve` is a one-dimensional geometry.
- A `MultiCurve` is simple if and only if all of its elements are simple; the only intersections between any two elements occur at points that are on the boundaries of both elements.
- A `MultiCurve` boundary is obtained by applying the “mod 2 union rule” (also known as the “odd-even rule”): A point is in the boundary of a `MultiCurve` if it is in the boundaries of an odd number of `MultiCurve` elements.
- A `MultiCurve` is closed if all of its elements are closed.
- The boundary of a closed `MultiCurve` is always empty.

17.2.11. Class `MultiLineString`

A `MultiLineString` is a `MultiCurve` geometry collection composed of `LineString` elements.

`MultiLineString` Examples

- On a region map, a `MultiLineString` could represent a river system or a highway system.

17.2.12. Class `MultiSurface`

A `MultiSurface` is a geometry collection composed of surface elements. `MultiSurface` is a non-instantiable class. Its only instantiable subclass is `MultiPolygon`.

`MultiSurface` Assertions

- Two `MultiSurface` surfaces have no interiors that intersect.
- Two `MultiSurface` elements have boundaries that intersect at most at a finite number of points.

17.2.13. Class `MultiPolygon`

A `MultiPolygon` is a `MultiSurface` object composed of `Polygon` elements.

`MultiPolygon` Examples

- On a region map, a `MultiPolygon` could represent a system of lakes.

`MultiPolygon` Assertions

- A `MultiPolygon` has no two `Polygon` elements with interiors that intersect.
- A `MultiPolygon` has no two `Polygon` elements that cross (crossing is also forbidden by the previous assertion), or that touch at an infinite number of points.
- A `MultiPolygon` may not have cut lines, spikes, or punctures. A `MultiPolygon` is a regular, closed point set.
- A `MultiPolygon` that has more than one `Polygon` has an interior that is not connected. The number of connected components of the interior of a `MultiPolygon` is equal to the number of `Polygon` values in the `MultiPolygon`.

`MultiPolygon` Properties

- A `MultiPolygon` is a two-dimensional geometry.
- A `MultiPolygon` boundary is a set of closed curves (`LineString` values) corresponding to the boundaries of its `Polygon` elements.
- Each `Curve` in the boundary of the `MultiPolygon` is in the boundary of exactly one `Polygon` element.
- Every `Curve` in the boundary of an `Polygon` element is in the boundary of the `MultiPolygon`.

17.3. Supported Spatial Data Formats

This section describes the standard spatial data formats that are used to represent geometry objects in queries. They are:

- Well-Known Text (WKT) format
- Well-Known Binary (WKB) format

Internally, MySQL stores geometry values in a format that is not identical to either WKT or WKB format.

17.3.1. Well-Known Text (WKT) Format

The Well-Known Text (WKT) representation of Geometry is designed to exchange geometry data in ASCII form.

Examples of WKT representations of geometry objects:

- A [Point](#):

```
POINT(15 20)
```

Note that point coordinates are specified with no separating comma.

- A [LineString](#) with four points:

```
LINESTRING(0 0, 10 10, 20 25, 50 60)
```

Note that point coordinate pairs are separated by commas.

- A [Polygon](#) with one exterior ring and one interior ring:

```
POLYGON((0 0,10 0,10 10,0 10,0 0),(5 5,7 5,7 7,5 7, 5 5))
```

- A [MultiPoint](#) with three [Point](#) values:

```
MULTIPOINT(0 0, 20 20, 60 60)
```

- A [MultiLineString](#) with two [LineString](#) values:

```
MULTILINESTRING((10 10, 20 20), (15 15, 30 15))
```

- A [MultiPolygon](#) with two [Polygon](#) values:

```
MULTIPOLYGON(((0 0,10 0,10 10,0 10,0 0)),((5 5,7 5,7 7,5 7, 5 5)))
```

- A [GeometryCollection](#) consisting of two [Point](#) values and one [LineString](#):

```
GEOMETRYCOLLECTION(POINT(10 10), POINT(30 30), LINESTRING(15 15, 20 20))
```

A Backus-Naur grammar that specifies the formal production rules for writing WKT values can be found in the OpenGIS specification document referenced near the beginning of this chapter.

17.3.2. Well-Known Binary (WKB) Format

The Well-Known Binary (WKB) representation for geometric values is defined by the OpenGIS spe-

cification. It is also defined in the ISO *SQL/MM Part 3: Spatial* standard.

WKB is used to exchange geometry data as binary streams represented by `BLOB` values containing geometric WKB information.

WKB uses one-byte unsigned integers, four-byte unsigned integers, and eight-byte double-precision numbers (IEEE 754 format). A byte is eight bits.

For example, a WKB value that corresponds to `POINT(1 1)` consists of this sequence of 21 bytes (each represented here by two hex digits):

```
010100000000000000000000F03F000000000000F03F
```

The sequence may be broken down into these components:

```
Byte order : 01
WKB type   : 01000000
X          : 00000000000000F03F
Y          : 00000000000000F03F
```

Component representation is as follows:

- The byte order may be either 0 or 1 to indicate little-endian or big-endian storage. The little-endian and big-endian byte orders are also known as Network Data Representation (NDR) and External Data Representation (XDR), respectively.
- The WKB type is a code that indicates the geometry type. Values from 1 through 7 indicate `Point`, `LineString`, `Polygon`, `MultiPoint`, `MultiLineString`, `MultiPolygon`, and `GeometryCollection`.
- A `Point` value has X and Y coordinates, each represented as a double-precision value.

WKB values for more complex geometry values are represented by more complex data structures, as detailed in the OpenGIS specification.

17.4. Creating a Spatially Enabled MySQL Database

This section describes the data types you can use for representing spatial data in MySQL, and the functions available for creating and retrieving spatial values.

17.4.1. MySQL Spatial Data Types

MySQL has data types that correspond to OpenGIS classes. Some of these types hold single geometry values:

- `GEOMETRY`
- `POINT`
- `LINestring`
- `POLYGON`

`GEOMETRY` can store geometry values of any type. The other single-value types (`POINT`, `LINES-`

`TRING`, and `POLYGON`) restrict their values to a particular geometry type.

The other data types hold collections of values:

- `MULTIPOINT`
- `MULTILINESTRING`
- `MULTIPOLYGON`
- `GEOMETRYCOLLECTION`

`GEOMETRYCOLLECTION` can store a collection of objects of any type. The other collection types (`MULTIPOINT`, `MULTILINESTRING`, `MULTIPOLYGON`, and `GEOMETRYCOLLECTION`) restrict collection members to those having a particular geometry type.

17.4.2. Creating Spatial Values

This section describes how to create spatial values using Well-Known Text and Well-Known Binary functions that are defined in the OpenGIS standard, and using MySQL-specific functions.

17.4.2.1. Creating Geometry Values Using WKT Functions

MySQL provides a number of functions that take as input parameters a Well-Known Text representation and, optionally, a spatial reference system identifier (SRID). They return the corresponding geometry.

`GeomFromText()` accepts a WKT of any geometry type as its first argument. An implementation also provides type-specific construction functions for construction of geometry values of each geometry type.

- `GeomCollFromText(wkt[,srid]), GeometryCollectionFromText(wkt[,srid])`
Constructs a `GEOMETRYCOLLECTION` value using its WKT representation and SRID.
- `GeomFromText(wkt[,srid]), GeometryFromText(wkt[,srid])`
Constructs a geometry value of any type using its WKT representation and SRID.
- `LineFromText(wkt[,srid]), LineStringFromText(wkt[,srid])`
Constructs a `LINestring` value using its WKT representation and SRID.
- `MLineFromText(wkt[,srid]), MultiLineStringFromText(wkt[,srid])`
Constructs a `MULTILINESTRING` value using its WKT representation and SRID.
- `MPointFromText(wkt[,srid]), MultiPointFromText(wkt[,srid])`
Constructs a `MULTIPOINT` value using its WKT representation and SRID.
- `MPolyFromText(wkt[,srid]), MultiPolygonFromText(wkt[,srid])`
Constructs a `MULTIPOLYGON` value using its WKT representation and SRID.
- `PointFromText(wkt[,srid])`
Constructs a `POINT` value using its WKT representation and SRID.

- `PolyFromText(wkt[,srid]), PolygonFromText(wkt[,srid])`

Constructs a `POLYGON` value using its WKT representation and SRID.

The OpenGIS specification also defines the following optional functions, which MySQL does not implement. These functions construct `Polygon` or `MultiPolygon` values based on the WKT representation of a collection of rings or closed `LineString` values. These values may intersect.

- `BdMPolyFromText(wkt,srid)`

Constructs a `MultiPolygon` value from a `MultiLineString` value in WKT format containing an arbitrary collection of closed `LineString` values.

- `BdPolyFromText(wkt,srid)`

Constructs a `Polygon` value from a `MultiLineString` value in WKT format containing an arbitrary collection of closed `LineString` values.

17.4.2.2. Creating Geometry Values Using WKB Functions

MySQL provides a number of functions that take as input parameters a `BLOB` containing a Well-Known Binary representation and, optionally, a spatial reference system identifier (SRID). They return the corresponding geometry.

`GeomFromWKB()` accepts a WKB of any geometry type as its first argument. An implementation also provides type-specific construction functions for construction of geometry values of each geometry type.

- `GeomCollFromWKB(wkb[,srid]), GeometryCollectionFromWKB(wkb[,srid])`

Constructs a `GEOMETRYCOLLECTION` value using its WKB representation and SRID.

- `GeomFromWKB(wkb[,srid]), GeometryFromWKB(wkb[,srid])`

Constructs a geometry value of any type using its WKB representation and SRID.

- `LineFromWKB(wkb[,srid]), LineStringFromWKB(wkb[,srid])`

Constructs a `LINESTRING` value using its WKB representation and SRID.

- `MLineFromWKB(wkb[,srid]), MultiLineStringFromWKB(wkb[,srid])`

Constructs a `MULTILINESTRING` value using its WKB representation and SRID.

- `MPointFromWKB(wkb[,srid]), MultiPointFromWKB(wkb[,srid])`

Constructs a `MULTIPOINT` value using its WKB representation and SRID.

- `MPolyFromWKB(wkb[,srid]), MultiPolygonFromWKB(wkb[,srid])`

Constructs a `MULTIPOLYGON` value using its WKB representation and SRID.

- `PointFromWKB(wkb[,srid])`

Constructs a `POINT` value using its WKB representation and SRID.

- `PolyFromWKB(wkb[,srid]), PolygonFromWKB(wkb[,srid])`

Constructs a `POLYGON` value using its WKB representation and SRID.

The OpenGIS specification also describes optional functions for constructing `Polygon` or `MultiPolygon` values based on the WKB representation of a collection of rings or closed `LineString` values. These values may intersect. MySQL does not implement these functions:

- `BdMPolyFromWKB(wkb,srid)`

Constructs a `MultiPolygon` value from a `MultiLineString` value in WKB format containing an arbitrary collection of closed `LineString` values.

- `BdPolyFromWKB(wkb,srid)`

Constructs a `Polygon` value from a `MultiLineString` value in WKB format containing an arbitrary collection of closed `LineString` values.

17.4.2.3. Creating Geometry Values Using MySQL-Specific Functions

MySQL provides a set of useful non-standard functions for creating geometry WKB representations. The functions described in this section are MySQL extensions to the OpenGIS specification. The results of these functions are `BLOB` values containing WKB representations of geometry values with no SRID. The results of these functions can be substituted as the first argument for any function in the `GeomFromWKB()` function family.

- `GeometryCollection(g1,g2,...)`

Constructs a WKB `GeometryCollection`. If any argument is not a well-formed WKB representation of a geometry, the return value is `NULL`.

- `LineString(pt1,pt2,...)`

Constructs a WKB `LineString` value from a number of WKB `Point` arguments. If any argument is not a WKB `Point`, the return value is `NULL`. If the number of `Point` arguments is less than two, the return value is `NULL`.

- `MultiLineString(ls1,ls2,...)`

Constructs a WKB `MultiLineString` value using WKB `LineString` arguments. If any argument is not a WKB `LineString`, the return value is `NULL`.

- `MultiPoint(pt1,pt2,...)`

Constructs a WKB `MultiPoint` value using WKB `Point` arguments. If any argument is not a WKB `Point`, the return value is `NULL`.

- `MultiPolygon(poly1,poly2,...)`

Constructs a WKB `MultiPolygon` value from a set of WKB `Polygon` arguments. If any argument is not a WKB `Polygon`, the return value is `NULL`.

- `Point(x,y)`

Constructs a WKB `Point` using its coordinates.

- `Polygon(ls1, ls2, ...)`

Constructs a WKB `Polygon` value from a number of WKB `LineString` arguments. If any argument does not represent the WKB of a `LinearRing` (that is, not a closed and simple `LineString`) the return value is `NULL`.

17.4.3. Creating Spatial Columns

MySQL provides a standard way of creating spatial columns for geometry types, for example, with `CREATE TABLE` or `ALTER TABLE`. Currently, spatial columns are supported for `MyISAM`, `InnoDB`, `NDB`, and `ARCHIVE` tables. See also the annotations about spatial indexes under [Section 17.6.1, “Creating Spatial Indexes”](#).

- Use the `CREATE TABLE` statement to create a table with a spatial column:

```
CREATE TABLE geom (g GEOMETRY);
```

- Use the `ALTER TABLE` statement to add or drop a spatial column to or from an existing table:

```
ALTER TABLE geom ADD pt POINT;
ALTER TABLE geom DROP pt;
```

17.4.4. Populating Spatial Columns

After you have created spatial columns, you can populate them with spatial data.

Values should be stored in internal geometry format, but you can convert them to that format from either Well-Known Text (WKT) or Well-Known Binary (WKB) format. The following examples demonstrate how to insert geometry values into a table by converting WKT values into internal geometry format:

- Perform the conversion directly in the `INSERT` statement:

```
INSERT INTO geom VALUES (GeomFromText('POINT(1 1)'));
SET @g = 'POINT(1 1)';
INSERT INTO geom VALUES (GeomFromText(@g));
```

- Perform the conversion prior to the `INSERT`:

```
SET @g = GeomFromText('POINT(1 1)');
INSERT INTO geom VALUES (@g);
```

The following examples insert more complex geometries into the table:

```
SET @g = 'LINESTRING(0 0,1 1,2 2)';
INSERT INTO geom VALUES (GeomFromText(@g));

SET @g = 'POLYGON((0 0,10 0,10 10,0 10,0 0),(5 5,7 5,7 7,5 7, 5 5))';
INSERT INTO geom VALUES (GeomFromText(@g));

SET @g =
'GEOMETRYCOLLECTION(POINT(1 1),LINESTRING(0 0,1 1,2 2,3 3,4 4))';
INSERT INTO geom VALUES (GeomFromText(@g));
```

The preceding examples all use `GeomFromText()` to create geometry values. You can also use type-

specific functions:

```
SET @g = 'POINT(1 1)';
INSERT INTO geom VALUES (PointFromText(@g));

SET @g = 'LINESTRING(0 0,1 1,2 2)';
INSERT INTO geom VALUES (LineStringFromText(@g));

SET @g = 'POLYGON((0 0,10 0,10 10,0 10,0 0),(5 5,7 5,7 7,5 7, 5 5))';
INSERT INTO geom VALUES (PolygonFromText(@g));

SET @g =
'GEOMETRYCOLLECTION(POINT(1 1),LINESTRING(0 0,1 1,2 2,3 3,4 4))';
INSERT INTO geom VALUES (GeomCollFromText(@g));
```

Note that if a client application program wants to use WKB representations of geometry values, it is responsible for sending correctly formed WKB in queries to the server. However, there are several ways of satisfying this requirement. For example:

- Inserting a `POINT(1 1)` value with hex literal syntax:

```
mysql> INSERT INTO geom VALUES
-> (GeomFromWKB(0x010100000000000000000000F03F000000000000F03F));
```

- An ODBC application can send a WKB representation, binding it to a placeholder using an argument of `BLOB` type:

```
INSERT INTO geom VALUES (GeomFromWKB(?))
```

Other programming interfaces may support a similar placeholder mechanism.

- In a C program, you can escape a binary value using `mysql_real_escape_string()` and include the result in a query string that is sent to the server. See [Section 24.2.3.52](#), “`mysql_real_escape_string()`”.

17.4.5. Fetching Spatial Data

Geometry values stored in a table can be fetched in internal format. You can also convert them into WKT or WKB format.

- Fetching spatial data in internal format:

Fetching geometry values using internal format can be useful in table-to-table transfers:

```
CREATE TABLE geom2 (g GEOMETRY) SELECT g FROM geom;
```

- Fetching spatial data in WKT format:

The `AsText()` function converts a geometry from internal format into a WKT string.

```
SELECT AsText(g) FROM geom;
```

- Fetching spatial data in WKB format:

The `AsBinary()` function converts a geometry from internal format into a `BLOB` containing the WKB value.

```
SELECT AsBinary(g) FROM geom;
```

17.5. Analyzing Spatial Information

After populating spatial columns with values, you are ready to query and analyze them. MySQL provides a set of functions to perform various operations on spatial data. These functions can be grouped into four major categories according to the type of operation they perform:

- Functions that convert geometries between various formats
- Functions that provide access to qualitative or quantitative properties of a geometry
- Functions that describe relations between two geometries
- Functions that create new geometries from existing ones

Spatial analysis functions can be used in many contexts, such as:

- Any interactive SQL program, such as `mysql` or MySQL Query Browser
- Application programs written in any language that supports a MySQL client API

17.5.1. Geometry Format Conversion Functions

MySQL supports the following functions for converting geometry values between internal format and either WKT or WKB format:

- `AsBinary(g)`

Converts a value in internal geometry format to its WKB representation and returns the binary result.

```
SELECT AsBinary(g) FROM geom;
```

- `AsText(g)`

Converts a value in internal geometry format to its WKT representation and returns the string result.

```
mysql> SET @g = 'LineString(1 1,2 2,3 3)';
mysql> SELECT AsText(GeomFromText(@g));
+-----+
| AsText(GeomFromText(@g)) |
+-----+
| LINESTRING(1 1,2 2,3 3) |
+-----+
```

- `GeomFromText(wkt[, srid])`

Converts a string value from its WKT representation into internal geometry format and returns the result. A number of type-specific functions are also supported, such as `PointFromText()` and `LineFromText()`. See [Section 17.4.2.1, “Creating Geometry Values Using WKT Functions”](#).

- `GeomFromWKB(wkb[, srid])`

Converts a binary value from its WKB representation into internal geometry format and returns the result. A number of type-specific functions are also supported, such as `PointFromWKB()` and `LineFromWKB()`. See [Section 17.4.2.2, “Creating Geometry Values Using WKB Functions”](#).

17.5.2. Geometry Functions

Each function that belongs to this group takes a geometry value as its argument and returns some quantitative or qualitative property of the geometry. Some functions restrict their argument type. Such functions return `NULL` if the argument is of an incorrect geometry type. For example, `Area()` returns `NULL` if the object type is neither `Polygon` nor `MultiPolygon`.

17.5.2.1. General Geometry Functions

The functions listed in this section do not restrict their argument and accept a geometry value of any type.

- `Dimension(g)`

Returns the inherent dimension of the geometry value *g*. The result can be `-1`, `0`, `1`, or `2`. The meaning of these values is given in [Section 17.2.2, “Class Geometry”](#).

```
mysql> SELECT Dimension(GeomFromText('LineString(1 1,2 2)'));
+-----+
| Dimension(GeomFromText('LineString(1 1,2 2)')) |
+-----+
| 1 |
+-----+
```

- `Envelope(g)`

Returns the Minimum Bounding Rectangle (MBR) for the geometry value *g*. The result is returned as a `Polygon` value.

The polygon is defined by the corner points of the bounding box:

```
POLYGON((MINX MINY, MAXX MINY, MAXX MAXY, MINX MAXY, MINX MINY))
```

```
mysql> SELECT AsText(Envelope(GeomFromText('LineString(1 1,2 2)')));
+-----+
| AsText(Envelope(GeomFromText('LineString(1 1,2 2)'))) |
+-----+
| POLYGON((1 1,2 1,2 2,1 2,1 1)) |
+-----+
```

- `GeometryType(g)`

Returns as a string the name of the geometry type of which the geometry instance *g* is a member. The name corresponds to one of the instantiable `Geometry` subclasses.

```
mysql> SELECT GeometryType(GeomFromText('POINT(1 1)'));
+-----+
| GeometryType(GeomFromText('POINT(1 1)')) |
+-----+
| POINT |
+-----+
```

- `SRID(g)`

Returns an integer indicating the Spatial Reference System ID for the geometry value *g*.

In MySQL, the SRID value is just an integer associated with the geometry value. All calculations are done assuming Euclidean (planar) geometry.

```
mysql> SELECT SRID(GeomFromText('LineString(1 1,2 2)',101));
+-----+
```

17.5.2.3. LineString Functions

A `LineString` consists of `Point` values. You can extract particular points of a `LineString`, count the number of points that it contains, or obtain its length.

- `EndPoint(ls)`

Returns the `Point` that is the endpoint of the `LineString` value `ls`.

```
mysql> SET @ls = 'LineString(1 1,2 2,3 3)';
mysql> SELECT AsText(EndPoint(GeomFromText(@ls)));
+-----+
| AsText(EndPoint(GeomFromText(@ls))) |
+-----+
| POINT(3 3) |
+-----+
```

- `GLength(ls)`

Returns as a double-precision number the length of the `LineString` value `ls` in its associated spatial reference.

```
mysql> SET @ls = 'LineString(1 1,2 2,3 3)';
mysql> SELECT GLength(GeomFromText(@ls));
+-----+
| GLength(GeomFromText(@ls)) |
+-----+
| 2.8284271247462 |
+-----+
```

`GLength()` is a non-standard name. It corresponds to the OpenGIS `Length()` function.

- `NumPoints(ls)`

Returns the number of `Point` objects in the `LineString` value `ls`.

```
mysql> SET @ls = 'LineString(1 1,2 2,3 3)';
mysql> SELECT NumPoints(GeomFromText(@ls));
+-----+
| NumPoints(GeomFromText(@ls)) |
+-----+
| 3 |
+-----+
```

- `PointN(ls,N)`

Returns the `N`-th `Point` in the `LineString` value `ls`. Points are numbered beginning with 1.

```
mysql> SET @ls = 'LineString(1 1,2 2,3 3)';
mysql> SELECT AsText(PointN(GeomFromText(@ls),2));
+-----+
| AsText(PointN(GeomFromText(@ls),2)) |
+-----+
| POINT(2 2) |
+-----+
```

- `StartPoint(ls)`

Returns the `Point` that is the start point of the `LineString` value `ls`.

```
mysql> SET @ls = 'LineString(1 1,2 2,3 3)';
mysql> SELECT AsText(StartPoint(GeomFromText(@ls)));
+-----+
| AsText(StartPoint(GeomFromText(@ls))) |
+-----+
```

```
+-----+
| POINT(1 1) |
+-----+
```

The OpenGIS specification also defines the following function, which MySQL does not implement:

- `IsRing(ls)`

Returns 1 if the `LineString` value `ls` is closed (that is, its `StartPoint()` and `EndPoint()` values are the same) and is simple (does not pass through the same point more than once). Returns 0 if `ls` is not a ring, and -1 if it is `NULL`.

17.5.2.4. MultiLineString Functions

- `GLength(mls)`

Returns as a double-precision number the length of the `MultiLineString` value `mls`. The length of `mls` is equal to the sum of the lengths of its elements.

```
mysql> SET @mls = 'MultiLineString((1 1,2 2,3 3),(4 4,5 5))';
mysql> SELECT GLength(GeomFromText(@mls));
+-----+
| GLength(GeomFromText(@mls)) |
+-----+
| 4.2426406871193 |
+-----+
```

`GLength()` is a non-standard name. It corresponds to the OpenGIS `Length()` function.

- `IsClosed(mls)`

Returns 1 if the `MultiLineString` value `mls` is closed (that is, the `StartPoint()` and `EndPoint()` values are the same for each `LineString` in `mls`). Returns 0 if `mls` is not closed, and -1 if it is `NULL`.

```
mysql> SET @mls = 'MultiLineString((1 1,2 2,3 3),(4 4,5 5))';
mysql> SELECT IsClosed(GeomFromText(@mls));
+-----+
| IsClosed(GeomFromText(@mls)) |
+-----+
| 0 |
+-----+
```

17.5.2.5. Polygon Functions

- `Area(poly)`

Returns as a double-precision number the area of the `Polygon` value `poly`, as measured in its spatial reference system.

```
mysql> SET @poly = 'Polygon((0 0,0 3,3 0,0 0),(1 1,1 2,2 1,1 1))';
mysql> SELECT Area(GeomFromText(@poly));
+-----+
| Area(GeomFromText(@poly)) |
+-----+
| 4 |
+-----+
```

- `ExteriorRing(poly)`

Returns the exterior ring of the `Polygon` value *poly* as a `LineString`.

```
mysql> SET @poly =
-> 'Polygon((0 0,0 3,3 3,3 0,0 0),(1 1,1 2,2 2,2 1,1 1))';
mysql> SELECT AsText(ExteriorRing(GeomFromText(@poly)));
+-----+
| AsText(ExteriorRing(GeomFromText(@poly))) |
+-----+
| LINESTRING(0 0,0 3,3 3,3 0,0 0)          |
+-----+
```

- `InteriorRingN(poly,N)`

Returns the *N*-th interior ring for the `Polygon` value *poly* as a `LineString`. Rings are numbered beginning with 1.

```
mysql> SET @poly =
-> 'Polygon((0 0,0 3,3 3,3 0,0 0),(1 1,1 2,2 2,2 1,1 1))';
mysql> SELECT AsText(InteriorRingN(GeomFromText(@poly),1));
+-----+
| AsText(InteriorRingN(GeomFromText(@poly),1)) |
+-----+
| LINESTRING(1 1,1 2,2 2,2 1,1 1)              |
+-----+
```

- `NumInteriorRings(poly)`

Returns the number of interior rings in the `Polygon` value *poly*.

```
mysql> SET @poly =
-> 'Polygon((0 0,0 3,3 3,3 0,0 0),(1 1,1 2,2 2,2 1,1 1))';
mysql> SELECT NumInteriorRings(GeomFromText(@poly));
+-----+
| NumInteriorRings(GeomFromText(@poly)) |
+-----+
| 1 |
+-----+
```

17.5.2.6. MultiPolygon Functions

- `Area(mpoly)`

Returns as a double-precision number the area of the `MultiPolygon` value *mpoly*, as measured in its spatial reference system.

```
mysql> SET @mpoly =
-> 'MultiPolygon(((0 0,0 3,3 3,3 0,0 0),(1 1,1 2,2 2,2 1,1 1)))';
mysql> SELECT Area(GeomFromText(@mpoly));
+-----+
| Area(GeomFromText(@mpoly)) |
+-----+
| 8 |
+-----+
```

The OpenGIS specification also defines the following functions, which MySQL does not implement:

- `Centroid(mpoly)`

Returns the mathematical centroid for the `MultiPolygon` value `mpoly` as a `Point`. The result is not guaranteed to be on the `MultiPolygon`.

- `PointOnSurface(mpoly)`

Returns a `Point` value that is guaranteed to be on the `MultiPolygon` value `mpoly`.

17.5.2.7. GeometryCollection Functions

- `GeometryN(gc,N)`

Returns the *N*-th geometry in the `GeometryCollection` value `gc`. Geometries are numbered beginning with 1.

```
mysql> SET @gc = 'GeometryCollection(Point(1 1),LineString(2 2, 3 3))';
mysql> SELECT AsText(GeometryN(GeomFromText(@gc),1));
```

```
+-----+
| AsText(GeometryN(GeomFromText(@gc),1)) |
+-----+
| POINT(1 1)                             |
+-----+
```

- `NumGeometries(gc)`

Returns the number of geometries in the `GeometryCollection` value `gc`.

```
mysql> SET @gc = 'GeometryCollection(Point(1 1),LineString(2 2, 3 3))';
mysql> SELECT NumGeometries(GeomFromText(@gc));
```

```
+-----+

17.5.3. Functions That Create New Geometries from Existing Ones

17.5.3.1. Geometry Functions That Produce New Geometries

Section 17.5.2, “Geometry Functions”, discusses several functions that construct new geometries from existing ones. See that section for descriptions of these functions:

- `Envelope(g)`
- `StartPoint(ls)`
- `EndPoint(ls)`
- `PointN(ls,N)`
- `ExteriorRing(poly)`
- `InteriorRingN(poly,N)`
- `GeometryN(gc,N)`

17.5.3.2. Spatial Operators

OpenGIS proposes a number of other functions that can produce geometries. They are designed to implement spatial operators.

These functions are not implemented in MySQL. They may appear in future releases.

- `Buffer(g,d)`
Returns a geometry that represents all points whose distance from the geometry value *g* is less than or equal to a distance of *d*.
- `ConvexHull(g)`
Returns a geometry that represents the convex hull of the geometry value *g*.
- `Difference(g1,g2)`
Returns a geometry that represents the point set difference of the geometry value *g1* with *g2*.
- `Intersection(g1,g2)`
Returns a geometry that represents the point set intersection of the geometry values *g1* with *g2*.
- `SymDifference(g1,g2)`
Returns a geometry that represents the point set symmetric difference of the geometry value *g1* with *g2*.
- `Union(g1,g2)`
Returns a geometry that represents the point set union of the geometry values *g1* and *g2*.

17.5.4. Functions for Testing Spatial Relations Between Geometric Objects

The functions described in these sections take two geometries as input parameters and return a qualitative or quantitative relation between them.

17.5.5. Relations on Geometry Minimal Bounding Rectangles (MBRs)

MySQL provides several functions that test relations between minimal bounding rectangles of two geometries *g1* and *g2*. The return values 1 and 0 indicate true and false, respectively.

- `MBRContains(g1,g2)`
Returns 1 or 0 to indicate whether the Minimum Bounding Rectangle of *g1* contains the Minimum Bounding Rectangle of *g2*.

```
mysql> SET @g1 = GeomFromText('Polygon((0 0,0 3,3 3,3 0,0 0))');
mysql> SET @g2 = GeomFromText('Point(1 1)');
mysql> SELECT MBRContains(@g1,@g2), MBRContains(@g2,@g1);
-----+-----
| MBRContains(@g1,@g2) | MBRContains(@g2,@g1) |
```

1	0
---	---

- `MBRDisjoint(g1,g2)`

Returns 1 or 0 to indicate whether the Minimum Bounding Rectangles of the two geometries *g1* and *g2* are disjoint (do not intersect).
- `MBREqual(g1,g2)`

Returns 1 or 0 to indicate whether the Minimum Bounding Rectangles of the two geometries *g1* and *g2* are the same.
- `MBRIntersects(g1,g2)`

Returns 1 or 0 to indicate whether the Minimum Bounding Rectangles of the two geometries *g1* and *g2* intersect.
- `MBROverlaps(g1,g2)`

Returns 1 or 0 to indicate whether the Minimum Bounding Rectangles of the two geometries *g1* and *g2* overlap.
- `MBRTouches(g1,g2)`

Returns 1 or 0 to indicate whether the Minimum Bounding Rectangles of the two geometries *g1* and *g2* touch.
- `MBRWithin(g1,g2)`

Returns 1 or 0 to indicate whether the Minimum Bounding Rectangle of *g1* is within the Minimum Bounding Rectangle of *g2*.

```
mysql> SET @g1 = GeomFromText('Polygon((0 0,0 3,3 3,3 0,0 0))');
mysql> SET @g2 = GeomFromText('Polygon((0 0,0 5,5 5,5 0,0 0))');
mysql> SELECT MBRWithin(@g1,@g2), MBRWithin(@g2,@g1);
```

MBRWithin(@g1,@g2)	MBRWithin(@g2,@g1)
1	0

17.5.6. Functions That Test Spatial Relationships Between Geometries

The OpenGIS specification defines the following functions. They test the relationship between two geometry values *g1* and *g2*.

Currently, MySQL does not implement these functions according to the specification. Those that are implemented return the same result as the corresponding MBR-based functions. This includes functions in the following list other than `Distance()` and `Related()`.

These functions may be implemented in future releases with full support for spatial analysis, not just MBR-based support.

The return values 1 and 0 indicate true and false, respectively.

- `Contains(g1,g2)`

Returns 1 or 0 to indicate whether *g1* completely contains *g2*.

- `Crosses(g1,g2)`

Returns 1 if *g1* spatially crosses *g2*. Returns `NULL` if *g1* is a `Polygon` or a `MultiPolygon`, or if *g2* is a `Point` or a `MultiPoint`. Otherwise, returns 0.

The term *spatially crosses* denotes a spatial relation between two given geometries that has the following properties:

- The two geometries intersect
- Their intersection results in a geometry that has a dimension that is one less than the maximum dimension of the two given geometries
- Their intersection is not equal to either of the two given geometries

- `Disjoint(g1,g2)`

Returns 1 or 0 to indicate whether *g1* is spatially disjoint from (does not intersect) *g2*.

- `Distance(g1,g2)`

Returns as a double-precision number the shortest distance between any two points in the two geometries.

- `Equals(g1,g2)`

Returns 1 or 0 to indicate whether *g1* is spatially equal to *g2*.

- `Intersects(g1,g2)`

Returns 1 or 0 to indicate whether *g1* spatially intersects *g2*.

- `Overlaps(g1,g2)`

Returns 1 or 0 to indicate whether *g1* spatially overlaps *g2*. The term *spatially overlaps* is used if two geometries intersect and their intersection results in a geometry of the same dimension but not equal to either of the given geometries.

- `Related(g1,g2,pattern_matrix)`

Returns 1 or 0 to indicate whether the spatial relationship specified by *pattern_matrix* exists between *g1* and *g2*. Returns -1 if the arguments are `NULL`. The pattern matrix is a string. Its specification will be noted here if this function is implemented.

- `Touches(g1,g2)`

Returns 1 or 0 to indicate whether *g1* spatially touches *g2*. Two geometries *spatially touch* if the interiors of the geometries do not intersect, but the boundary of one of the geometries intersects either the boundary or the interior of the other.

- `Within(g1,g2)`

Returns 1 or 0 to indicate whether *g1* is spatially within *g2*.

17.6. Optimizing Spatial Analysis

Search operations in non-spatial databases can be optimized using indexes. This is true for spatial databases as well. With the help of a great variety of multi-dimensional indexing methods that have previously been designed, it is possible to optimize spatial searches. The most typical of these are:

- Point queries that search for all objects that contain a given point
- Region queries that search for all objects that overlap a given region

MySQL uses **R-Trees with quadratic splitting** to index spatial columns. A spatial index is built using the MBR of a geometry. For most geometries, the MBR is a minimum rectangle that surrounds the geometries. For a horizontal or a vertical linestring, the MBR is a rectangle degenerated into the linestring. For a point, the MBR is a rectangle degenerated into the point.

It is also possible to create normal indexes on spatial columns. You are required to declare a prefix for any (non-spatial) index on a spatial column except for `POINT` columns.

17.6.1. Creating Spatial Indexes

MySQL can create spatial indexes using syntax similar to that for creating regular indexes, but extended with the `SPATIAL` keyword. Currently, spatial columns that are indexed must be declared `NOT NULL`. The following examples demonstrate how to create spatial indexes:

- With `CREATE TABLE`:

```
CREATE TABLE geom (g GEOMETRY NOT NULL, SPATIAL INDEX(g));
```

- With `ALTER TABLE`:

```
ALTER TABLE geom ADD SPATIAL INDEX(g);
```

- With `CREATE INDEX`:

```
CREATE SPATIAL INDEX sp_index ON geom (g);
```

For `MyISAM` tables, `SPATIAL INDEX` creates an R-tree index. For other storage engines that support spatial indexing, `SPATIAL INDEX` creates a B-tree index. A B-tree index on spatial values will be useful for exact-value lookups, but not for range scans.

To drop spatial indexes, use `ALTER TABLE` or `DROP INDEX`:

- With `ALTER TABLE`:

```
ALTER TABLE geom DROP INDEX g;
```

- With `DROP INDEX`:

```
DROP INDEX sp_index ON geom;
```

Example: Suppose that a table `geom` contains more than 32,000 geometries, which are stored in the

column `g` of type `GEOMETRY`. The table also has an `AUTO_INCREMENT` column `fid` for storing object ID values.

```
mysql> DESCRIBE geom;
+-----+-----+-----+-----+-----+-----+
| Field | Type      | Null | Key | Default | Extra          |
+-----+-----+-----+-----+-----+-----+
| fid   | int(11)   |      | PRI | NULL    | auto_increment |
| g     | geometry  |      |     |         |                |
+-----+-----+-----+-----+-----+-----+
2 rows in set (0.00 sec)

mysql> SELECT COUNT(*) FROM geom;
+-----+
| count(*) |
+-----+
|      32376 |
+-----+
1 row in set (0.00 sec)
```

To add a spatial index on the column `g`, use this statement:

```
mysql> ALTER TABLE geom ADD SPATIAL INDEX(g);
Query OK, 32376 rows affected (4.05 sec)
Records: 32376 Duplicates: 0 Warnings: 0
```

17.6.2. Using a Spatial Index

The optimizer investigates whether available spatial indexes can be involved in the search for queries that use a function such as `MBRContains()` or `MBRWithin()` in the `WHERE` clause. The following query finds all objects that are in the given rectangle:

```
mysql> SET @poly =
-> 'Polygon((30000 15000,
           31000 15000,
           31000 16000,
           30000 16000,
           30000 15000))';
mysql> SELECT fid,AsText(g) FROM geom WHERE
-> MBRContains(GeomFromText(@poly),g);
+-----+-----+
| fid | AsText(g) |
+-----+-----+
| 21 | LINESTRING(30350.4 15828.8,30350.6 15845,30333.8 15845,30 ... |

| 7 | LINESTRING(30200.6 15059.4,30185.6 15058.6,30186 15048.8, ... |
| 10 | LINESTRING(30179.6 15017.8,30181 15002.8,30190.8 15003.6, ... |
| 11 | LINESTRING(30154.2 15000.4,30168.6 15004.8,30166 15014.2, ... |
| 13 | LINESTRING(30105 15065.8,30108.4 15050.8,30118 15053,3011 ... |
| 154 | LINESTRING(30276.2 15143.8,30261.4 15141,30263 15131.4,30 ... |
| 155 | LINESTRING(30269.8 15084,30269.4 15093.4,30258.6 15093,30 ... |
| 157 | LINESTRING(30128.2 15011,30113.2 15010.2,30113.6 15000.4, ... |
+-----+-----+
20 rows in set (0.00 sec)
```

Use `EXPLAIN` to check the way this query is executed:

```
mysql> SET @poly =
-> 'Polygon((30000 15000,
           31000 15000,
           31000 16000,
```

```

                                30000 16000,
                                30000 15000)';
mysql> EXPLAIN SELECT fid,AsText(g) FROM geom WHERE
-> MBRContains(GeomFromText(@poly),g)\G
***** 1. row *****
      id: 1
  select_type: SIMPLE
        table: geom
         type: range
possible_keys: g
          key: g
         key_len: 32
          ref: NULL
         rows: 50
       Extra: Using where
1 row in set (0.00 sec)

```

Check what would happen without a spatial index:

```

mysql> SET @poly =
-> 'Polygon((30000 15000,
                                31000 15000,
                                31000 16000,
                                30000 16000,
                                30000 15000))';
mysql> EXPLAIN SELECT fid,AsText(g) FROM g IGNORE INDEX (g) WHERE
-> MBRContains(GeomFromText(@poly),g)\G
***** 1. row *****
      id: 1
  select_type: SIMPLE
        table: geom
         type: ALL
possible_keys: NULL
          key: NULL
         key_len: NULL
          ref: NULL
         rows: 32376
       Extra: Using where
1 row in set (0.00 sec)

```

Executing the `SELECT` statement without the spatial index yields the same result but causes the execution time to rise from 0.00 seconds to 0.46 seconds:

```

mysql> SET @poly =
-> 'Polygon((30000 15000,
                                31000 15000,
                                31000 16000,
                                30000 16000,
                                30000 15000))';
mysql> SELECT fid,AsText(g) FROM geom IGNORE INDEX (g) WHERE
-> MBRContains(GeomFromText(@poly),g);
+-----+-----+
| fid | AsText(g) |
+-----+-----+
| 1 | LINESTRING(30250.4 15129.2,30248.8 15138.4,30238.2 15136. ... |

| 249 | LINESTRING(30337.8 15938.6,30337.8 15946.8,30320.4 15946. ... |
+-----+-----+
20 rows in set (0.46 sec)

```

In future releases, spatial indexes may also be used for optimizing other functions. See [Section 17.5.4, “Functions for Testing Spatial Relations Between Geometric Objects”](#).

17.7. MySQL Conformance and Compatibility

MySQL does not yet implement the following GIS features:

- Additional Metadata Views

OpenGIS specifications propose several additional metadata views. For example, a system view named `GEOMETRY_COLUMNS` contains a description of geometry columns, one row for each geometry column in the database.

- The OpenGIS function `Length()` on `LineString` and `MultiLineString` currently should be called in MySQL as `GLength()`

The problem is that there is an existing SQL function `Length()` that calculates the length of string values, and sometimes it is not possible to distinguish whether the function is called in a textual or spatial context. We need either to solve this somehow, or decide on another function name.

Chapter 18. Stored Procedures and Functions

Stored routines (procedures and functions) are supported in MySQL 5.1. A stored procedure is a set of SQL statements that can be stored in the server. Once this has been done, clients don't need to keep reissuing the individual statements but can refer to the stored procedure instead.

Some situations where stored routines can be particularly useful:

- When multiple client applications are written in different languages or work on different platforms, but need to perform the same database operations.
- When security is paramount. Banks, for example, use stored procedures and functions for all common operations. This provides a consistent and secure environment, and routines can ensure that each operation is properly logged. In such a setup, applications and users would have no access to the database tables directly, but can only execute specific stored routines.

Stored routines can provide improved performance because less information needs to be sent between the server and the client. The tradeoff is that this does increase the load on the database server because more of the work is done on the server side and less is done on the client (application) side. Consider this if many client machines (such as Web servers) are serviced by only one or a few database servers.

Stored routines also allow you to have libraries of functions in the database server. This is a feature shared by modern application languages that allow such design internally (for example, by using classes). Using these client application language features is beneficial for the programmer even outside the scope of database use.

MySQL follows the SQL:2003 syntax for stored routines, which is also used by IBM's DB2.

The MySQL implementation of stored routines is still in progress. All syntax described in this chapter is supported and any limitations and extensions are documented where appropriate. Further discussion of restrictions on use of stored routines is given in [Section I.1, “Restrictions on Stored Routines and Triggers”](#).

Binary logging for stored routines takes place as described in [Section 18.5, “Binary Logging of Stored Routines and Triggers”](#).

Recursive stored procedures are disabled by default, but can be enabled on the server by setting the `max_sp_recursion_depth` server system variable to a nonzero value. See [Section 5.2.3, “System Variables”](#), for more information.

Stored functions cannot be recursive. See [Section I.1, “Restrictions on Stored Routines and Triggers”](#).

18.1. Stored Routines and the Grant Tables

Stored routines require the `proc` table in the `mysql` database. This table is created during the MySQL 5.1 installation procedure. If you are upgrading to MySQL 5.1 from an earlier version, be sure to update your grant tables to make sure that the `proc` table exists. See [Section 5.6.2, “mysql_upgrade — Check Tables for MySQL Upgrade”](#).

The server manipulates the `mysql.proc` table in response to statements that create, alter, or drop stored routines. It is not supported that the server will notice manual manipulation of this table.

The MySQL grant system takes stored routines into account as follows:

- The `CREATE ROUTINE` privilege is needed to create stored routines.
- The `ALTER ROUTINE` privilege is needed to alter or drop stored routines. This privilege is granted automatically to the creator of a routine.
- The `EXECUTE` privilege is required to execute stored routines. However, this privilege is granted automatically to the creator of a routine. Also, the default `SQL SECURITY` characteristic for a routine is `DEFINER`, which enables users who have access to the database with which the routine is associated to execute the routine.

18.2. Stored Routine Syntax

A stored routine is either a procedure or a function. Stored routines are created with `CREATE PROCEDURE` and `CREATE FUNCTION` statements. A procedure is invoked using a `CALL` statement, and can only pass back values using output variables. A function can be called from inside a statement just like any other function (that is, by invoking the function's name), and can return a scalar value. Stored routines may call other stored routines.

A stored procedure or function is associated with a particular database. This has several implications:

- When the routine is invoked, an implicit `USE db_name` is performed (and undone when the routine terminates). `USE` statements within stored routines are disallowed.
- You can qualify routine names with the database name. This can be used to refer to a routine that is not in the current database. For example, to invoke a stored procedure `p` or function `f` that is associated with the `test` database, you can say `CALL test.p()` or `test.f()`.
- When a database is dropped, all stored routines associated with it are dropped as well.

MySQL supports the very useful extension that allows the use of regular `SELECT` statements (that is, without using cursors or local variables) inside a stored procedure. The result set of such a query is simply sent directly to the client. Multiple `SELECT` statements generate multiple result sets, so the client must use a MySQL client library that supports multiple result sets. This means the client must use a client library from a version of MySQL at least as recent as 4.1. The client should also specify the `CLIENT_MULTI_STATEMENTS` option when it connects. For C programs, this can be done with the `mysql_real_connect()` C API function (see [Section 24.2.3.51](#), “`mysql_real_connect()`”).

The following sections describe the syntax used to create, alter, drop, and invoke stored procedures and functions.

18.2.1. `CREATE PROCEDURE` and `CREATE FUNCTION` Syntax

```
CREATE
  [DEFINER = { user | CURRENT_USER }]
  PROCEDURE sp_name ([proc_parameter[,...]])
  [characteristic ...] routine_body

CREATE
  [DEFINER = { user | CURRENT_USER }]
  FUNCTION sp_name ([func_parameter[,...]])
  RETURNS type
  [characteristic ...] routine_body

proc_parameter:
  [ IN | OUT | INOUT ] param_name type

func_parameter:
  param_name type

type:
```

```

Any valid MySQL data type

characteristic:
  LANGUAGE SQL
  { [NOT] DETERMINISTIC
    { CONTAINS SQL | NO SQL | READS SQL DATA | MODIFIES SQL DATA }
  SQL SECURITY { DEFINER | INVOKER }
  COMMENT 'string'

routine_body:
  Valid SQL procedure statement

```

These statements create stored routines. To use them, it is necessary to have the `CREATE ROUTINE` privilege. If binary logging is enabled, the `CREATE FUNCTION` statement might also require the `SUPER` privilege, as described in [Section 18.5, “Binary Logging of Stored Routines and Triggers”](#). MySQL automatically grants the `ALTER ROUTINE` and `EXECUTE` privileges to the routine creator.

By default, the routine is associated with the default database. To associate the routine explicitly with a given database, specify the name as `db_name.sp_name` when you create it.

If the routine name is the same as the name of a built-in SQL function, you must use a space between the name and the following parenthesis when defining the routine, or a syntax error occurs. This is also true when you invoke the routine later. For this reason, we suggest that it is better to avoid re-using the names of existing SQL functions for your own stored routines.

The `IGNORE_SPACE` SQL mode applies to built-in functions, not to stored routines. It is always allowable to have spaces after a routine name, regardless of whether `IGNORE_SPACE` is enabled.

The parameter list enclosed within parentheses must always be present. If there are no parameters, an empty parameter list of `()` should be used.

Each parameter can be declared to use any valid data type, except that the `COLLATE` attribute cannot be used.

Each parameter is an `IN` parameter by default. To specify otherwise for a parameter, use the keyword `OUT` or `INOUT` before the parameter name.

Note: Specifying a parameter as `IN`, `OUT`, or `INOUT` is valid only for a `PROCEDURE`. (`FUNCTION` parameters are always regarded as `IN` parameters.)

An `IN` parameter passes a value into a procedure. The procedure might modify the value, but the modification is not visible to the caller when the procedure returns. An `OUT` parameter passes a value from the procedure back to the caller. Its initial value is `NULL` within the procedure, and its value is visible to the caller when the procedure returns. An `INOUT` parameter is initialized by the caller, can be modified by the procedure, and any change made by the procedure is visible to the caller when the procedure returns.

For each `OUT` or `INOUT` parameter, pass a user-defined variable so that you can obtain its value when the procedure returns. (For an example, see [Section 18.2.4, “CALL Statement Syntax”](#).) If you are calling the procedure from within another stored procedure or function, you can also pass a routine parameter or local routine variable as an `IN` or `INOUT` parameter.

The `RETURNS` clause may be specified only for a `FUNCTION`, for which it is mandatory. It indicates the return type of the function, and the function body must contain a `RETURN value` statement.

The `routine_body` consists of a valid SQL procedure statement. This can be a simple statement such as `SELECT` or `INSERT`, or it can be a compound statement written using `BEGIN` and `END`. Compound statement syntax is described in [Section 18.2.5, “BEGIN . . . END Compound Statement Syntax”](#). Compound statements can contain declarations, loops, and other control structure statements. The syntax for these statements is described later in this chapter. See, for example, [Section 18.2.6, “DECLARE Statement Syntax”](#), and [Section 18.2.10, “Flow Control Constructs”](#). Some statements are not allowed in stored routines; see [Section I.1, “Restrictions on Stored Routines and Triggers”](#).

The `CREATE FUNCTION` statement was used in earlier versions of MySQL to support UDFs (user-defined functions). See [Section 26.3, “Adding New Functions to MySQL”](#). UDFs continue to be supported, even with the existence of stored functions. A UDF can be regarded as an external stored function. However, do note that stored functions share their namespace with UDFs.

A procedure or function is considered “deterministic” if it always produces the same result for the same input parameters, and “not deterministic” otherwise. If neither `DETERMINISTIC` nor `NOT DETERMINISTIC` is given in the routine definition, the default is `NOT DETERMINISTIC`.

A routine that contains the `NOW()` function (or its synonyms) or `RAND()` is non-deterministic, but it might still be replication-safe. For `NOW()`, the binary log includes the timestamp and replicates correctly. `RAND()` also replicates correctly as long as it is invoked only once within a routine. (You can consider the routine execution timestamp and random number seed as implicit inputs that are identical on the master and slave.)

Currently, the `DETERMINISTIC` characteristic is accepted, but not yet used by the optimizer. However, if binary logging is enabled, this characteristic affects which routine definitions MySQL accepts. See [Section 18.5, “Binary Logging of Stored Routines and Triggers”](#).

Several characteristics provide information about the nature of data use by the routine. `CONTAINS SQL` indicates that the routine does not contain statements that read or write data. `NO SQL` indicates that the routine contains no SQL statements. `READS SQL DATA` indicates that the routine contains statements that read data, but not statements that write data. `MODIFIES SQL DATA` indicates that the routine contains statements that may write data. `CONTAINS SQL` is the default if none of these characteristics is given explicitly. These characteristics are advisory only. The server does not use them to constrain what kinds of statements a routine will be allowed to execute.

The `SQL SECURITY` characteristic can be used to specify whether the routine should be executed using the permissions of the user who creates the routine or the user who invokes it. The default value is `DEFINER`. This feature is new in SQL:2003. The creator or invoker must have permission to access the database with which the routine is associated. It is necessary to have the `EXECUTE` privilege to be able to execute the routine. The user that must have this privilege is either the definer or invoker, depending on how the `SQL SECURITY` characteristic is set.

The optional `DEFINER` clause specifies the MySQL account to be used when checking access privileges at routine execution time for routines that have the `SQL SECURITY DEFINER` characteristic. The `DEFINER` clause was added in MySQL 5.1.8.

If a `user` value is given, it should be a MySQL account in `'user_name'@'host_name'` format (the same format used in the `GRANT` statement). The `user_name` and `host_name` values both are required. `CURRENT_USER` also can be given as `CURRENT_USER()`. The default `DEFINER` value is the user who executes the `CREATE PROCEDURE` or `CREATE FUNCTION` or statement. (This is the same as `DEFINER = CURRENT_USER`.)

If you specify the `DEFINER` clause, you cannot set the value to any account but your own unless you have the `SUPER` privilege. These rules determine the legal `DEFINER` user values:

- If you do not have the `SUPER` privilege, the only legal `user` value is your own account, either specified literally or by using `CURRENT_USER`. You cannot set the definer to some other account.
- If you have the `SUPER` privilege, you can specify any syntactically legal account name. If the account does not actually exist, a warning is generated.

Although it is possible to create routines with a non-existent `DEFINER` value, an error occurs if the routine executes with definer privileges but the definer does not exist at execution time.

MySQL stores the `sql_mode` system variable setting that is in effect at the time a routine is created,

and always executes the routine with this setting in force.

When the routine is invoked, an implicit `USE db_name` is performed (and undone when the routine terminates). `USE` statements within stored routines are disallowed.

The server uses the data type of a routine parameter or function return value as follows. These rules also apply to local routine variables created with the `DECLARE` statement (Section 18.2.7.1, “`DECLARE Local Variables`”).

- Assignments are checked for data type mismatches and overflow. Conversion and overflow problems result in warnings, or errors in strict mode.
- For character data types, if there is a `CHARACTER SET` clause in the declaration, the specified character set and its default collation are used. If there is no such clause, the database character set and collation that are in effect at the time the routine is created are used. (These are given by the values of the `character_set_database` and `collation_database` system variables.) The `COLLATE` attribute is not supported. (This includes use of `BINARY`, because in this context `BINARY` specifies the binary collation of the character set.)
- Only scalar values can be assigned to parameters or variables. For example, a statement such as `SET x = (SELECT 1, 2)` is invalid.

The `COMMENT` clause is a MySQL extension, and may be used to describe the stored routine. This information is displayed by the `SHOW CREATE PROCEDURE` and `SHOW CREATE FUNCTION` statements.

MySQL allows routines to contain DDL statements, such as `CREATE` and `DROP`. MySQL also allows stored procedures (but not stored functions) to contain SQL transaction statements such as `COMMIT`. Stored functions may not contain statements that do explicit or implicit commit or rollback. Support for these statements is not required by the SQL standard, which states that each DBMS vendor may decide whether to allow them.

Stored routines cannot use `LOAD DATA INFILE`.

Statements that return a result set cannot be used within a stored function. This includes `SELECT` statements that do not use `INTO` to fetch column values into variables, `SHOW` statements, and other statements such as `EXPLAIN`. For statements that can be determined at function definition time to return a result set, a `Not allowed to return a result set from a function` error occurs (`ER_SP_NO_RETSET_IN_FUNC`). For statements that can be determined only at runtime to return a result set, a `PROCEDURE %s can't return a result set in the given context` error occurs (`ER_SP_BADSELECT`).

The following is an example of a simple stored procedure that uses an `OUT` parameter. The example uses the `mysql` client `delimiter` command to change the statement delimiter from `;` to `//` while the procedure is being defined. This allows the `;` delimiter used in the procedure body to be passed through to the server rather than being interpreted by `mysql` itself.

```
mysql> delimiter //
mysql> CREATE PROCEDURE simpleproc (OUT param1 INT)
-> BEGIN
->   SELECT COUNT(*) INTO param1 FROM t;
-> END;
-> //
Query OK, 0 rows affected (0.00 sec)

mysql> delimiter ;
mysql> CALL simpleproc(@a);
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT @a;
```

```
+-----+
| @a   |
+-----+
| 3    |
+-----+
1 row in set (0.00 sec)
```

When using the `delimiter` command, you should avoid the use of the backslash (`\`) character because that is the escape character for MySQL.

The following is an example of a function that takes a parameter, performs an operation using an SQL function, and returns the result. In this case, it is unnecessary to use `delimiter` because the function definition contains no internal `;` statement delimiters:

```
mysql> CREATE FUNCTION hello (s CHAR(20)) RETURNS CHAR(50)
-> RETURN CONCAT('Hello, ',s,'!');
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT hello('world');
+-----+
| hello('world') |
+-----+
| Hello, world!  |
+-----+
1 row in set (0.00 sec)
```

A stored function returns a value of the data type specified in its `RETURNS` clause. If the `RETURN` statement returns a value of a different type, the value is coerced to the proper type. For example, if a function returns an `ENUM` or `SET` value, but the `RETURN` statement returns an integer, the value returned from the function is the string for the corresponding `ENUM` member of set of `SET` members.

18.2.2. ALTER PROCEDURE and ALTER FUNCTION Syntax

```
ALTER {PROCEDURE | FUNCTION} sp_name [characteristic ...]

characteristic:
{ CONTAINS SQL | NO SQL | READS SQL DATA | MODIFIES SQL DATA }
| SQL SECURITY { DEFINER | INVOKER }
| COMMENT 'string'
```

This statement can be used to change the characteristics of a stored procedure or function. You must have the `ALTER ROUTINE` privilege for the routine. (That privilege is granted automatically to the routine creator.) If binary logging is enabled, the `ALTER FUNCTION` statement might also require the `SUPER` privilege, as described in [Section 18.5, “Binary Logging of Stored Routines and Triggers”](#).

More than one change may be specified in an `ALTER PROCEDURE` or `ALTER FUNCTION` statement.

18.2.3. DROP PROCEDURE and DROP FUNCTION Syntax

```
DROP {PROCEDURE | FUNCTION} [IF EXISTS] sp_name
```

This statement is used to drop a stored procedure or function. That is, the specified routine is removed from the server. You must have the `ALTER ROUTINE` privilege for the routine. (That privilege is granted automatically to the routine creator.)

The `IF EXISTS` clause is a MySQL extension. It prevents an error from occurring if the procedure or function does not exist. A warning is produced that can be viewed with `SHOW WARNINGS`.

18.2.4. CALL Statement Syntax

```
CALL sp_name(parameter[,...])
```

The `CALL` statement invokes a procedure that was defined previously with `CREATE PROCEDURE`.

`CALL` can pass back values to its caller using parameters that are declared as `OUT` or `INOUT` parameters. It also “returns” the number of rows affected, which a client program can obtain at the SQL level by calling the `ROW_COUNT()` function and from C by calling the `mysql_affected_rows()` C API function.

To get back a value from a procedure using an `OUT` or `INOUT` parameter, pass the parameter by means of a user variable, and then check the value of the variable after the procedure returns. (If you are calling the procedure from within another stored procedure or function, you can also pass a routine parameter or local routine variable as an `IN` or `INOUT` parameter.) For an `INOUT` parameter, initialize its value before passing it to the procedure. The following procedure has an `OUT` parameter that the procedure sets to the current server version, and an `INOUT` value that the procedure increments by one from its current value:

```
CREATE PROCEDURE p (OUT ver_param VARCHAR(25), INOUT incr_param INT)
BEGIN
  # Set value of OUT parameter
  SELECT VERSION() INTO ver_param;
  # Increment value of INOUT parameter
  SET incr_param = incr_param + 1;
END;
```

Before calling the procedure, initialize the variable to be passed as the `INOUT` parameter. After calling the procedure, the values of the two variables will have been set or modified:

```
mysql> SET @increment = 10;
mysql> CALL p(@version, @increment);
mysql> SELECT @version, @increment;
+-----+-----+
| @version | @increment |
+-----+-----+
| 5.1.12-beta-log | 11 |
+-----+-----+
```

If you write C programs that execute stored procedures with the `CALL` SQL statement, you *must* set the `CLIENT_MULTI_RESULTS` flag when you call `mysql_real_connect()`, either explicitly, or implicitly by setting `CLIENT_MULTI_STATEMENTS`. This is because each `CALL` returns a result to indicate the call status, in addition to any results sets that might be returned by statements executed within the procedure. To process the result of a `CALL` statement, use a loop that calls `mysql_next_result()` to determine whether there are more results. For an example, see [Section 24.2.9, “C API Handling of Multiple Statement Execution”](#).

18.2.5. `BEGIN . . . END` Compound Statement Syntax

```
[begin_label:] BEGIN
  [statement_list]
END [end_label]
```

`BEGIN . . . END` syntax is used for writing compound statements, which can appear within stored routines and triggers. A compound statement can contain multiple statements, enclosed by the `BEGIN` and `END` keywords. `statement_list` represents a list of one or more statements. Each statement within `statement_list` must be terminated by a semicolon (`;`) statement delimiter. Note that `statement_list` is optional, which means that the empty compound statement (`BEGIN END`) is legal.

Use of multiple statements requires that a client is able to send statement strings containing the `;` statement delimiter. This is handled in the `mysql` command-line client with the `delimiter` command. Changing the `;` end-of-statement delimiter (for example, to `//`) allows `;` to be used in a routine body. For an example, see [Section 18.2.1, “CREATE PROCEDURE and CREATE FUNCTION Syntax”](#).

A compound statement can be labeled. `end_label` cannot be given unless `begin_label` also is present. If both are present, they must be the same.

The optional `[NOT] ATOMIC` clause is not yet supported. This means that no transactional savepoint is set at the start of the instruction block and the `BEGIN` clause used in this context has no effect on the current transaction.

18.2.6. DECLARE Statement Syntax

The `DECLARE` statement is used to define various items local to a routine:

- Local variables. See [Section 18.2.7, “Variables in Stored Routines”](#).
- Conditions and handlers. See [Section 18.2.8, “Conditions and Handlers”](#).
- Cursors. See [Section 18.2.9, “Cursors”](#).

The `SIGNAL` and `RESIGNAL` statements are not currently supported.

`DECLARE` is allowed only inside a `BEGIN . . . END` compound statement and must be at its start, before any other statements.

Declarations must follow a certain order. Cursors must be declared before declaring handlers, and variables and conditions must be declared before declaring either cursors or handlers.

18.2.7. Variables in Stored Routines

You may declare and use variables within a routine.

18.2.7.1. DECLARE Local Variables

```
DECLARE var_name[,...] type [DEFAULT value]
```

This statement is used to declare local variables. To provide a default value for the variable, include a `DEFAULT` clause. The value can be specified as an expression; it need not be a constant. If the `DEFAULT` clause is missing, the initial value is `NULL`.

Local variables are treated like routine parameters with respect to data type and overflow checking. See [Section 18.2.1, “CREATE PROCEDURE and CREATE FUNCTION Syntax”](#).

The scope of a local variable is within the `BEGIN . . . END` block where it is declared. The variable can be referred to in blocks nested within the declaring block, except those blocks that declare a variable with the same name.

18.2.7.2. Variable SET Statement

```
SET var_name = expr [, var_name = expr] ...
```

The `SET` statement in stored routines is an extended version of the general `SET` statement. Referenced variables may be ones declared inside a routine, or global system variables.

The `SET` statement in stored routines is implemented as part of the pre-existing `SET` syntax. This allows an extended syntax of `SET a=x, b=y, . . .` where different variable types (locally declared variables and global and session server variables) can be mixed. This also allows combinations of local vari-

ables and some options that make sense only for system variables; in that case, the options are recognized but ignored.

18.2.7.3. **SELECT ... INTO Statement**

```
SELECT col_name[,...] INTO var_name[,...] table_expr
```

This **SELECT** syntax stores selected columns directly into variables. Therefore, only a single row may be retrieved.

```
SELECT id,data INTO x,y FROM test.t1 LIMIT 1;
```

User variable names are not case sensitive. See [Section 9.3, “User-Defined Variables”](#).

Important: SQL variable names should not be the same as column names. If an SQL statement, such as a **SELECT ... INTO** statement, contains a reference to a column and a declared local variable with the same name, MySQL currently interprets the reference as the name of a variable. For example, in the following statement, `xname` is interpreted as a reference to the `xname` variable rather than the `xname` column:

```
CREATE PROCEDURE sp1 (x VARCHAR(5))
BEGIN
  DECLARE xname VARCHAR(5) DEFAULT 'bob';
  DECLARE newname VARCHAR(5);
  DECLARE xid INT;

  SELECT xname,id INTO newname,xid
    FROM table1 WHERE xname = xname;
  SELECT newname;
END;
```

When this procedure is called, the `newname` variable returns the value 'bob' regardless of the value of the `table1.xname` column.

See also [Section I.1, “Restrictions on Stored Routines and Triggers”](#).

18.2.8. Conditions and Handlers

Certain conditions may require specific handling. These conditions can relate to errors, as well as to general flow control inside a routine.

18.2.8.1. **DECLARE Conditions**

```
DECLARE condition_name CONDITION FOR condition_value

condition_value:
  SQLSTATE [VALUE] sqlstate_value
  | mysql_error_code
```

This statement specifies conditions that need specific handling. It associates a name with a specified error condition. The name can subsequently be used in a **DECLARE HANDLER** statement. See [Section 18.2.8.2, “DECLARE Handlers”](#).

A `condition_value` can be an SQLSTATE value or a MySQL error code.

18.2.8.2. **DECLARE Handlers**

```
DECLARE handler_type HANDLER FOR condition_value[,...] statement

handler_type:
  CONTINUE
```

```

EXIT
UNDO

condition_value:
  SQLSTATE [VALUE] sqlstate_value
  condition_name
  SQLWARNING
  NOT FOUND
  SQLEXCEPTION
  mysql_error_code

```

The `DECLARE ... HANDLER` statement specifies handlers that each may deal with one or more conditions. If one of these conditions occurs, the specified *statement* is executed. *statement* can be a simple statement (for example, `SET var_name = value`), or it can be a compound statement written using `BEGIN` and `END` (see [Section 18.2.5](#), “`BEGIN ... END Compound Statement Syntax`”).

For a `CONTINUE` handler, execution of the current routine continues after execution of the handler statement. For an `EXIT` handler, execution terminates for the `BEGIN ... END` compound statement in which the handler is declared. (This is true even if the condition occurs in an inner block.) The `UNDO` handler type statement is not yet supported.

If a condition occurs for which no handler has been declared, the default action is `EXIT`.

A *condition_value* can be any of the following values:

- An SQLSTATE value or a MySQL error code.
- A condition name previously specified with `DECLARE ... CONDITION`. See [Section 18.2.8.1](#), “`DECLARE Conditions`”.
- `SQLWARNING` is shorthand for all SQLSTATE codes that begin with `01`.
- `NOT FOUND` is shorthand for all SQLSTATE codes that begin with `02`.
- `SQLEXCEPTION` is shorthand for all SQLSTATE codes not caught by `SQLWARNING` or `NOT FOUND`.

Example:

```

mysql> CREATE TABLE test.t (s1 int,primary key (s1));
Query OK, 0 rows affected (0.00 sec)

mysql> delimiter //

mysql> CREATE PROCEDURE handlerdemo ()
-> BEGIN
->   DECLARE CONTINUE HANDLER FOR SQLSTATE '23000' SET @x2 = 1;
->   SET @x = 1;
->   INSERT INTO test.t VALUES (1);
->   SET @x = 2;
->   INSERT INTO test.t VALUES (1);
->   SET @x = 3;
-> END;
-> //
Query OK, 0 rows affected (0.00 sec)

mysql> CALL handlerdemo()//
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT @x//
+-----+
| @x    |
+-----+
| 3     |
+-----+
1 row in set (0.00 sec)

```

The example associates a handler with SQLSTATE 23000, which occurs for a duplicate-key error. Notice that @x is 3, which shows that MySQL executed to the end of the procedure. If the line `DECLARE CONTINUE HANDLER FOR SQLSTATE '23000' SET @x2 = 1;` had not been present, MySQL would have taken the default path (`EXIT`) after the second `INSERT` failed due to the `PRIMARY KEY` constraint, and `SELECT @x` would have returned 2.

If you want to ignore a condition, you can declare a `CONTINUE` handler for it and associate it with an empty block. For example:

```
DECLARE CONTINUE HANDLER FOR SQLWARNING BEGIN END;
```

18.2.9. Cursors

Simple cursors are supported inside stored procedures and functions. The syntax is as in embedded SQL. Cursors are currently asensitive, read-only, and non-scrolling. Asensitive means that the server may or may not make a copy of its result table.

Cursors must be declared before declaring handlers, and variables and conditions must be declared before declaring either cursors or handlers.

Example:

```
CREATE PROCEDURE curdemo()
BEGIN
  DECLARE done INT DEFAULT 0;
  DECLARE a CHAR(16);
  DECLARE b,c INT;
  DECLARE cur1 CURSOR FOR SELECT id,data FROM test.t1;
  DECLARE cur2 CURSOR FOR SELECT i FROM test.t2;
  DECLARE CONTINUE HANDLER FOR SQLSTATE '02000' SET done = 1;

  OPEN cur1;
  OPEN cur2;

  REPEAT
    FETCH cur1 INTO a, b;
    FETCH cur2 INTO c;
    IF NOT done THEN
      IF b < c THEN
        INSERT INTO test.t3 VALUES (a,b);
      ELSE
        INSERT INTO test.t3 VALUES (a,c);
      END IF;
    END IF;
  UNTIL done END REPEAT;

  CLOSE cur1;
  CLOSE cur2;
END
```

18.2.9.1. Declaring Cursors

```
DECLARE cursor_name CURSOR FOR select_statement
```

This statement declares a cursor. Multiple cursors may be declared in a routine, but each cursor in a given block must have a unique name.

The `SELECT` statement cannot have an `INTO` clause.

18.2.9.2. Cursor `OPEN` Statement

```
OPEN cursor_name
```

This statement opens a previously declared cursor.

18.2.9.3. Cursor **FETCH** Statement

```
FETCH cursor_name INTO var_name [, var_name] ...
```

This statement fetches the next row (if a row exists) using the specified open cursor, and advances the cursor pointer.

If no more rows are available, a No Data condition occurs with SQLSTATE value 02000. To detect this condition, you can set up a handler for it. An example is shown in [Section 18.2.9, “Cursors”](#).

18.2.9.4. Cursor **CLOSE** Statement

```
CLOSE cursor_name
```

This statement closes a previously opened cursor.

If not closed explicitly, a cursor is closed at the end of the compound statement in which it was declared.

18.2.10. Flow Control Constructs

The **IF**, **CASE**, **LOOP**, **WHILE**, **REPLACE ITERATE**, and **LEAVE** constructs are fully implemented.

Many of these constructs contain other statements, as indicated by the grammar specifications in the following sections. Such constructs may be nested. For example, an **IF** statement might contain a **WHILE** loop, which itself contains a **CASE** statement.

FOR loops are not currently supported.

18.2.10.1. **IF** Statement

```
IF search_condition THEN statement_list
  [ELSEIF search_condition THEN statement_list] ...
  [ELSE statement_list]
END IF
```

IF implements a basic conditional construct. If the *search_condition* evaluates to true, the corresponding SQL statement list is executed. If no *search_condition* matches, the statement list in the **ELSE** clause is executed. Each *statement_list* consists of one or more statements.

Note: There is also an **IF()** function, which differs from the **IF statement** described here. See [Section 12.2, “Control Flow Functions”](#).

18.2.10.2. **CASE** Statement

```
CASE case_value
  WHEN when_value THEN statement_list
  [WHEN when_value THEN statement_list] ...
  [ELSE statement_list]
END CASE
```

Or:

```
CASE
  WHEN search_condition THEN statement_list
  [WHEN search_condition THEN statement_list] ...
  [ELSE statement_list]
END CASE
```

The `CASE` statement for stored routines implements a complex conditional construct. If a `search_condition` evaluates to true, the corresponding SQL statement list is executed. If no search condition matches, the statement list in the `ELSE` clause is executed. Each `statement_list` consists of one or more statements.

Note: The syntax of the `CASE statement` shown here for use inside stored routines differs slightly from that of the SQL `CASE expression` described in Section 12.2, “Control Flow Functions”. The `CASE` statement cannot have an `ELSE NULL` clause, and it is terminated with `END CASE` instead of `END`.

18.2.10.3. LOOP Statement

```
[begin_label:] LOOP
    statement_list
END LOOP [end_label]
```

`LOOP` implements a simple loop construct, enabling repeated execution of the statement list, which consists of one or more statements. The statements within the loop are repeated until the loop is exited; usually this is accomplished with a `LEAVE` statement.

A `LOOP` statement can be labeled. `end_label` cannot be given unless `begin_label` also is present. If both are present, they must be the same.

18.2.10.4. LEAVE Statement

```
LEAVE label
```

This statement is used to exit any labeled flow control construct. It can be used within `BEGIN ... END` or loop constructs (`LOOP`, `REPEAT`, `WHILE`).

18.2.10.5. ITERATE Statement

```
ITERATE label
```

`ITERATE` can appear only within `LOOP`, `REPEAT`, and `WHILE` statements. `ITERATE` means “do the loop again.”

Example:

```
CREATE PROCEDURE doiterate(p1 INT)
BEGIN
    label1: LOOP
        SET p1 = p1 + 1;
        IF p1 < 10 THEN ITERATE label1; END IF;
        LEAVE label1;
    END LOOP label1;
    SET @x = p1;
END
```

18.2.10.6. REPEAT Statement

```
[begin_label:] REPEAT
    statement_list
UNTIL search_condition
END REPEAT [end_label]
```

The statement list within a `REPEAT` statement is repeated until the `search_condition` is true. Thus, a `REPEAT` always enters the loop at least once. `statement_list` consists of one or more statements.

A `REPEAT` statement can be labeled. `end_label` cannot be given unless `begin_label` also is present. If both are present, they must be the same.

Example:

```
mysql> delimiter //

mysql> CREATE PROCEDURE dorepeat(p1 INT)
-> BEGIN
->   SET @x = 0;
->   REPEAT SET @x = @x + 1; UNTIL @x > p1 END REPEAT;
-> END
-> //
Query OK, 0 rows affected (0.00 sec)

mysql> CALL dorepeat(1000)//
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT @x//
+-----+
| @x    |
+-----+
| 1001  |
+-----+
1 row in set (0.00 sec)
```

18.2.10.7. WHILE Statement

```
[begin_label:] WHILE search_condition DO
  statement_list
END WHILE [end_label]
```

The statement list within a `WHILE` statement is repeated as long as the `search_condition` is true. `statement_list` consists of one or more statements.

A `WHILE` statement can be labeled. `end_label` cannot be given unless `begin_label` also is present. If both are present, they must be the same.

Example:

```
CREATE PROCEDURE dowhile()
BEGIN
  DECLARE v1 INT DEFAULT 5;

  WHILE v1 > 0 DO
    ...
    SET v1 = v1 - 1;
  END WHILE;
END
```

18.3. Stored Procedures, Functions, Triggers, and `LAST_INSERT_ID()`

Within the body of a stored routine (procedure or function) or a trigger, the value of `LAST_INSERT_ID()` changes the same way as for statements executed outside the body of these kinds of objects (see [Section 12.10.3, “Information Functions”](#)). The effect of a stored routine or trigger upon the value of `LAST_INSERT_ID()` that is seen by following statements depends on the kind of routine:

- If a stored procedure executes statements that change the value of `LAST_INSERT_ID()`, the changed value will be seen by statements that follow the procedure call.

- For stored functions and triggers that change the value, the value is restored when the function or trigger ends, so following statements will not see a changed value.

18.4. Stored Procedures, Functions, Triggers, and Replication: Frequently Asked Questions

- Do MySQL 5.1 stored procedures and functions work with replication?

Yes, standard actions carried out in stored procedures and functions are replicated from a master MySQL server to a slave server. There are a few limitations that are described in detail in [Section 18.5, “Binary Logging of Stored Routines and Triggers”](#).

- Are stored procedures and functions created on a master server replicated to a slave?

Yes, creation of stored procedures and functions carried out through normal DDL statements on a master server are replicated to a slave, so the objects will exist on both servers. `ALTER` and `DROP` statements for stored procedures and functions are also replicated.

- How are actions that take place inside stored procedures and functions replicated?

MySQL records each DML event that occurs in a stored procedure and replicates those individual actions to a slave server. The actual calls made to execute stored procedures are not replicated.

Stored functions that change data are logged as function invocations, not as the DML events that occur inside each function.

- Are there special security requirements for using stored procedures and functions together with replication?

Yes. Because a slave server has authority to execute any statement read from a master's binary log, special security constraints exist for using stored functions with replication. If replication or binary logging in general (for the purpose of point-in-time recovery) is active, then MySQL DBAs have two security options open to them:

- Any user wishing to create stored functions must be granted the `SUPER` privilege.
- Alternatively, a DBA can set the `log_bin_trust_function_creators` system variable to 1, which enables anyone with the standard `CREATE ROUTINE` privilege to create stored functions.
- What limitations exist for replicating stored procedure and function actions?

Non-deterministic (random) or time-based actions embedded in stored procedures may not replicate properly. By their very nature, randomly produced results are not predictable and cannot be exactly reproduced, and therefore, random actions replicated to a slave will not mirror those performed on a master. Note that declaring stored functions to be `DETERMINISTIC` or setting the `log_bin_trust_function_creators` system variable to 0 will not allow random-valued operations to be invoked.

In addition, time-based actions cannot be reproduced on a slave because the timing of such actions in a stored procedure is not reproducible through the binary log used for replication. It records only DML events and does not factor in timing constraints.

Finally, non-transactional tables for which errors occur during large DML actions (such as bulk inserts) may experience replication issues in that a master may be partially updated from DML activ-

ity, but no updates are done to the slave because of the errors that occurred. A workaround is for a function's DML actions to be carried out with the `IGNORE` keyword so that updates on the master that cause errors are ignored and updates that do not cause errors are replicated to the slave.

- Do the preceding limitations affect MySQL's ability to do point-in-time recovery?

The same limitations that affect replication do affect point-in-time recovery.

- What will MySQL do to correct the aforementioned limitations?

As of MySQL 5.1.5, you can choose either statement-based replication or row-based replication. The original replication implementation is based on statement-based binary logging. Row-based binary logging resolves the limitations mentioned earlier. For additional information, see [Section 6.3, “Row-Based Replication”](#).

- Do triggers work with replication?

Triggers and replication in MySQL 5.1 work the same as in most other database engines: Actions carried out through triggers on a master are not replicated to a slave server. Instead, triggers that exist on tables that reside on a MySQL master server need to be created on the corresponding tables on any MySQL slave servers so that the triggers activate on the slaves as well as the master.

- How are actions carried out through triggers on a master replicated to a slave?

First, the triggers that exist on a master must be re-created on the slave server. Once this is done, the replication flow works as any other standard DML statement that participates in replication. For example, consider a table `EMP` that has an `AFTER` insert trigger, which exists on a master MySQL server. The same `EMP` table and `AFTER` insert trigger exist on the slave server as well. The replication flow would be:

1. An `INSERT` statement is made to `EMP`.
2. The `AFTER` trigger on `EMP` activates.
3. The `INSERT` statement is written to the binary log.
4. The replication slave picks up the `INSERT` statement to `EMP` and executes it.
5. The `AFTER` trigger on `EMP` that exists on the slave activates.

18.5. Binary Logging of Stored Routines and Triggers

The binary log contains information about SQL statements that modify database contents. This information is stored in the form of “events” that describe the modifications. The binary log has two important purposes:

- For replication, the master server sends the events contained in its binary log to its slaves, which execute those events to make the same data changes that were made on the master. See [Section 6.2, “Replication Implementation Overview”](#).
- Certain data recovery operations require use of the binary log. After a backup file has been restored, the events in the binary log that were recorded after the backup was made are re-executed. These events bring databases up to date from the point of the backup. See [Section 5.10.2.2, “Using Backups for Recovery”](#).

This section describes how MySQL 5.1 handles binary logging for stored routines (procedures and functions) and triggers. It also states the current conditions that the implementation places on the use of stored routines, and then provides additional information about the reasons for these conditions.

In general, the issues described here result from the fact that binary logging occurs at the SQL statement level. A future MySQL release is expected to implement row-level binary logging, which specifies the changes to make to individual rows as a result of executing SQL statements.

Unless noted otherwise, the remarks here assume that you have enabled binary logging by starting the server with the `--log-bin` option. (See [Section 5.12.4, “The Binary Log”](#).) If the binary log is not enabled, replication is not possible, nor is the binary log available for data recovery.

The current conditions on the use of stored functions in MySQL 5.1 can be summarized as follows. These conditions do not apply to stored procedures and they do not apply unless binary logging is enabled.

- To create or alter a stored function, you must have the `SUPER` privilege, in addition to the `CREATE ROUTINE` or `ALTER ROUTINE` privilege that is normally required.
- When you create a stored function, you must declare either that it is deterministic or that it does not modify data. Otherwise, it may be unsafe for data recovery or replication.
- To relax the preceding conditions on function creation (that you must have the `SUPER` privilege and that a function must be declared deterministic or to not modify data), set the global `log_bin_trust_function_creators` system variable to 1. By default, this variable has a value of 0, but you can change it like this:

```
mysql> SET GLOBAL log_bin_trust_function_creators = 1;
```

You can also set this variable by using the `--log-bin-trust-function-creators` option when starting the server.

If binary logging is not enabled, `log_bin_trust_function_creators` does not apply and `SUPER` is not required for function creation.

Triggers are similar to stored functions, so the preceding remarks regarding functions also apply to triggers with the following exception: `CREATE TRIGGER` does not have an optional `DETERMINISTIC` characteristic, so triggers are assumed to be always deterministic. However, this assumption might in some cases be invalid. For example, the `UUID()` function is non-deterministic (and does not replicate). You should be careful about using such functions in triggers.

Triggers can update tables, so error messages similar to those for stored functions occur with `CREATE TRIGGER` if you do not have the `SUPER` privilege and `log_bin_trust_function_creators` is 0.

The following discussion provides additional detail about the logging implementation and its implications.

- The server writes `CREATE PROCEDURE`, `CREATE FUNCTION`, `ALTER PROCEDURE`, `ALTER FUNCTION`, `DROP PROCEDURE`, and `DROP FUNCTION` statements to the binary log.
- A stored function invocation is logged as a `SELECT` statement if the function changes data and occurs within a statement that would not otherwise be logged. This prevents non-replication of data changes that result from use of stored functions in non-logged statements. For example, `SELECT` statements are not written to the binary log, but a `SELECT` might invoke a stored function that makes changes. To handle this, a `SELECT func_name()` statement is written to the binary log

when the given function makes a change. Suppose that the following statements are executed on the master:

```
CREATE FUNCTION f1(a INT) RETURNS INT
BEGIN
  IF (a < 3) THEN
    INSERT INTO t2 VALUES (a);
  END IF;
END;

CREATE TABLE t1 (a INT);
INSERT INTO t1 VALUES (1),(2),(3);

SELECT f1(a) FROM t1;
```

When the `SELECT` statement executes, the function `f1()` is invoked three times. Two of those invocations insert a row, and MySQL logs a `SELECT` statement for each of them. That is, MySQL writes the following statements to the binary log:

```
SELECT f1(1);
SELECT f1(2);
```

The server also logs a `SELECT` statement for a stored function invocation when the function invokes a stored procedure that causes an error. In this case, the server writes the `SELECT` statement to the log along with the expected error code. On the slave, if the same error occurs, that is the expected result and replication continues. Otherwise, replication stops.

Note: Before MySQL 5.1.7, you will see these `SELECT func_name()` statements logged as `DO func_name()`. The change to `SELECT` was made because use of `DO` was found to yield insufficient control over error code checking.

- Logging stored function invocations rather than the statements executed by a function has a security implication for replication, which arises from two factors:
 - It is possible for a function to follow different execution paths on master and slave servers.
 - Statements executed on a slave are processed by the slave SQL thread which has full privileges.

The implication is that although a user must have the `CREATE ROUTINE` privilege to create a function, the user can write a function containing a dangerous statement that will execute only on the slave where the statement is processed by the SQL thread that has full privileges. For example, if the master and slave servers have server ID values of 1 and 2, respectively, a user on the master server could create and invoke an unsafe function `unsafe_func()` as follows:

```
mysql> delimiter //
mysql> CREATE FUNCTION unsafe_func () RETURNS INT
-> BEGIN
->   IF @@server_id=2 THEN dangerous_statement; END IF;
->   RETURN 1;
-> END;
-> //
mysql> delimiter ;
mysql> INSERT INTO t VALUES(unsafe_func());
```

The `CREATE FUNCTION` and `INSERT` statements are written to the binary log, so the slave will execute them. Because the slave SQL thread has full privileges, it will execute the dangerous statement. Thus, the function invocation has different effects on the master and slave and is not replication-safe.

To guard against this danger for servers that have binary logging enabled, stored function creators must have the `SUPER` privilege, in addition to the usual `CREATE ROUTINE` privilege that is required. Similarly, to use `ALTER FUNCTION`, you must have the `SUPER` privilege in addition to the `ALTER ROUTINE` privilege. Without the `SUPER` privilege, an error will occur:

```
ERROR 1419 (HY000): You do not have the SUPER privilege and binary logging is enabled (you *might* want to use the less safe log_bin_trust_function_creators variable)
```

If you do not want to require function creators to have the `SUPER` privilege (for example, if all users with the `CREATE ROUTINE` privilege on your system are experienced application developers), set the global `log_bin_trust_function_creators` system variable to 1. You can also set this variable by using the `--log-bin-trust-function-creators` option when starting the server. If binary logging is not enabled, `log_bin_trust_function_creators` does not apply and `SUPER` is not required for function creation.

- If a function that performs updates is non-deterministic, it is not repeatable. This can have two undesirable effects:
 - It will make a slave different from the master.
 - Restored data will be different from the original data.

To deal with these problems, MySQL enforces the following requirement: On a master server, creation and alteration of a function is refused unless you declare the function to be deterministic or to not modify data. Two sets of function characteristics apply here:

- The `DETERMINISTIC` and `NOT DETERMINISTIC` characteristics indicate whether a function always produces the same result for given inputs. The default is `NOT DETERMINISTIC` if neither characteristic is given, so you must specify `DETERMINISTIC` explicitly to declare that a function is deterministic.

Use of the `NOW()` function (or its synonyms) or `RAND()` does not necessarily make a function non-deterministic. For `NOW()`, the binary log includes the timestamp and replicates correctly. `RAND()` also replicates correctly as long as it is invoked only once within a function. (You can consider the function execution timestamp and random number seed as implicit inputs that are identical on the master and slave.)

`SYSDATE()` is not affected by the timestamps in the binary log, so it causes stored routines to be non-deterministic if statement-based logging is used. This does not occur if row-based logging is used, or if the server is started with the `--sysdate-is-now` option to cause `SYS-DATE()` to be an alias for `NOW()`.

- The `CONTAINS SQL`, `NO SQL`, `READS SQL DATA`, and `MODIFIES SQL DATA` characteristics provide information about whether the function reads or writes data. Either `NO SQL` or `READS SQL DATA` indicates that a function does not change data, but you must specify one of these explicitly because the default is `CONTAINS SQL` if no characteristic is given.

By default, for a `CREATE FUNCTION` statement to be accepted, `DETERMINISTIC` or one of `NO SQL` and `READS SQL DATA` must be specified explicitly. Otherwise an error occurs:

```
ERROR 1418 (HY000): This function has none of DETERMINISTIC, NO SQL, or READS SQL DATA in its declaration and binary logging is enabled (you *might* want to use the less safe log_bin_trust_function_creators variable)
```

If you set `log_bin_trust_function_creators` to 1, the requirement that functions be deterministic or not modify data is dropped.

Assessment of the nature of a function is based on the “honesty” of the creator: MySQL does not check that a function declared `DETERMINISTIC` contains no statements that produce non-deterministic results.

- Stored procedure calls are logged at the statement level rather than at the `CALL` level. That is, the server does not log the `CALL` statement, it logs those statements within the procedure that actually execute. As a result, the same changes that occur on the master will be observed on slave servers. This prevents problems that could result from a procedure having different execution paths on different machines.

In general, statements executed within a stored procedure are written to the binary log using the same rules that would apply were the statements to be executed in standalone fashion. Some special care is taken when logging procedure statements because statement execution within procedures is not quite the same as in non-procedure context:

- A statement to be logged might contain references to local procedure variables. These variables do not exist outside of stored procedure context, so a statement that refers to such a variable cannot be logged literally. Instead, each reference to a local variable is replaced by this construct for logging purposes:

```
NAME_CONST(var_name, var_value)
```

`var_name` is the local variable name, and `var_value` is a constant indicating the value that the variable has at the time the statement is logged. `NAME_CONST()` has a value of `var_value`, and a “name” of `var_name`. Thus, if you invoke this function directly, you get a result like this:

```
mysql> SELECT NAME_CONST('myname', 14);
+-----+
| myname |
+-----+
|      14 |
+-----+
```

`NAME_CONST()` allows a logged standalone statement to be executed on a slave with the same effect as the original statement that was executed on the master within a stored procedure.

- A statement to be logged might contain references to user-defined variables. To handle this, MySQL writes a `SET` statement to the binary log to make sure that the variable exists on the slave with the same value as on the master. For example, if a statement refers to a variable `@my_var`, that statement will be preceded in the binary log by the following statement, where `value` is the value of `@my_var` on the master:

```
SET @my_var = value;
```

- Procedure calls can occur within a committed or rolled-back transaction. Previously, `CALL` statements were logged even if they occurred within a rolled-back transaction. As of MySQL 5.0.12, transactional context is accounted for so that the transactional aspects of procedure execution are replicated correctly. That is, the server logs those statements within the procedure that actually execute and modify data, and also logs `BEGIN`, `COMMIT`, and `ROLLBACK` statements as necessary. For example, if a procedure updates only transactional tables and is executed within a transaction that is rolled back, those updates are not logged. If the procedure occurs within a committed transaction, `BEGIN` and `COMMIT` statements are logged with the updates. For a procedure that executes within a rolled-back transaction, its statements are logged using the same rules that would apply if the statements were executed in standalone fashion:
 - Updates to transactional tables are not logged.
 - Updates to non-transactional tables are logged because rollback does not cancel them.
 - Updates to a mix of transactional and non-transactional tables are logged surrounded by `BEGIN` and `ROLLBACK` so that slaves will make the same changes and rollbacks as on the master.

- A stored procedure call is *not* written to the binary log at the statement level if the procedure is invoked from within a stored function. In that case, the only thing logged is the statement that invokes the function (if it occurs within a statement that is logged) or a `DO` statement (if it occurs within a statement that is not logged). For this reason, care should be exercised in the use of stored functions that invoke a procedure, even if the procedure is otherwise safe in itself.

Chapter 19. Triggers

A trigger is a named database object that is associated with a table and that is activated when a particular event occurs for the table. For example, the following statements create a table and an `INSERT` trigger. The trigger sums the values inserted into one of the table's columns:

```
mysql> CREATE TABLE account (acct_num INT, amount DECIMAL(10,2));
Query OK, 0 rows affected (0.03 sec)

mysql> CREATE TRIGGER ins_sum BEFORE INSERT ON account
-> FOR EACH ROW SET @sum = @sum + NEW.amount;
Query OK, 0 rows affected (0.06 sec)
```

This chapter describes the syntax for creating and dropping triggers, and shows some examples of how to use them. Discussion of restrictions on use of triggers is given in [Section I.1, “Restrictions on Stored Routines and Triggers”](#). Remarks regarding binary logging as it applies to triggers are given in [Section 18.5, “Binary Logging of Stored Routines and Triggers”](#).

19.1. CREATE TRIGGER Syntax

```
CREATE
[DEFINER = { user | CURRENT_USER }]
TRIGGER trigger_name trigger_time trigger_event
ON tbl_name FOR EACH ROW trigger_stmt
```

This statement creates a new trigger. A trigger is a named database object that is associated with a table, and that activates when a particular event occurs for the table. Currently, `CREATE TRIGGER` requires the `TRIGGER` privilege for the table associated with the trigger. (This statement requires the `SUPER` privilege prior to MySQL 5.1.6.)

The trigger becomes associated with the table named `tbl_name`, which must refer to a permanent table. You cannot associate a trigger with a `TEMPORARY` table or a view.

When the trigger is activated, the `DEFINER` clause determines the privileges that apply, as described later in this section.

`trigger_time` is the trigger action time. It can be `BEFORE` or `AFTER` to indicate that the trigger activates before or after the statement that activated it.

`trigger_event` indicates the kind of statement that activates the trigger. The `trigger_event` can be one of the following:

- `INSERT`: The trigger is activated whenever a new row is inserted into the table; for example, through `INSERT`, `LOAD DATA`, and `REPLACE` statements.
- `UPDATE`: The trigger is activated whenever a row is modified; for example, through `UPDATE` statements.
- `DELETE`: The trigger is activated whenever a row is deleted from the table; for example, through `DELETE` and `REPLACE` statements. However, `DROP TABLE` and `TRUNCATE` statements on the table do *not* activate this trigger, because they do not use `DELETE`. Dropping a partition does not activate `DELETE` triggers, either. See [Section 13.2.9, “TRUNCATE Syntax”](#).

It is important to understand that the `trigger_event` does not represent a literal type of SQL statement that activates the trigger so much as it represents a type of table operation. For example, an `INSERT` trigger is activated by not only `INSERT` statements but also `LOAD DATA` statements because

both statements insert rows into a table.

A potentially confusing example of this is the `INSERT INTO ... ON DUPLICATE KEY UPDATE ...` syntax: a `BEFORE INSERT` trigger will activate for every row, followed by either an `AFTER INSERT` trigger or both the `BEFORE UPDATE` and `AFTER UPDATE` triggers, depending on whether there was a duplicate key for the row.

There cannot be two triggers for a given table that have the same trigger action time and event. For example, you cannot have two `BEFORE UPDATE` triggers for a table. But you can have a `BEFORE UPDATE` and a `BEFORE INSERT` trigger, or a `BEFORE UPDATE` and an `AFTER UPDATE` trigger.

`trigger_stmt` is the statement to execute when the trigger activates. If you want to execute multiple statements, use the `BEGIN ... END` compound statement construct. This also enables you to use the same statements that are allowable within stored routines. See [Section 18.2.5, “BEGIN ... END Compound Statement Syntax”](#). Some statements are not allowed in triggers; see [Section I.1, “Restrictions on Stored Routines and Triggers”](#).

Note: Currently, triggers are not activated by cascaded foreign key actions. This limitation will be lifted as soon as possible.

In MySQL 5.1, you can write triggers containing direct references to tables by name, such as the trigger named `testref` shown in this example:

```
CREATE TABLE test1(a1 INT);
CREATE TABLE test2(a2 INT);
CREATE TABLE test3(a3 INT NOT NULL AUTO_INCREMENT PRIMARY KEY);
CREATE TABLE test4(
  a4 INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
  b4 INT DEFAULT 0
);

DELIMITER |

CREATE TRIGGER testref BEFORE INSERT ON test1
FOR EACH ROW BEGIN
  INSERT INTO test2 SET a2 = NEW.a1;
  DELETE FROM test3 WHERE a3 = NEW.a1;
  UPDATE test4 SET b4 = b4 + 1 WHERE a4 = NEW.a1;
END;
|

DELIMITER ;

INSERT INTO test3 (a3) VALUES
(NULL), (NULL), (NULL), (NULL), (NULL),
(NULL), (NULL), (NULL), (NULL), (NULL);

INSERT INTO test4 (a4) VALUES
(0), (0), (0), (0), (0), (0), (0), (0), (0), (0);
```

Suppose that you insert the following values into table `test1` as shown here:

```
mysql> INSERT INTO test1 VALUES
-> (1), (3), (1), (7), (1), (8), (4), (4);
Query OK, 8 rows affected (0.01 sec)
Records: 8 Duplicates: 0 Warnings: 0
```

As a result, the data in the four tables will be as follows:

```
mysql> SELECT * FROM test1;
+-----+
| a1    |
+-----+
| 1     |
| 3     |
| 1     |
| 7     |
| 1     |
| 8     |
| 4     |
| 4     |
+-----+
```

```

      4 |
      4 |
+-----+
8 rows in set (0.00 sec)

mysql> SELECT * FROM test2;
+-----+
| a2 |
+-----+
| 1 |
| 3 |
| 1 |
| 7 |
| 1 |
| 8 |
| 4 |
| 4 |
+-----+
8 rows in set (0.00 sec)

mysql> SELECT * FROM test3;
+-----+
| a3 |
+-----+
| 2 |
| 5 |
| 6 |
| 9 |
| 10 |
+-----+
5 rows in set (0.00 sec)

mysql> SELECT * FROM test4;
+-----+
| a4 | b4 |
+-----+
| 1 | 3 |
| 2 | 0 |
| 3 | 1 |
| 4 | 2 |
| 5 | 0 |
| 6 | 0 |
| 7 | 1 |
| 8 | 1 |
| 9 | 0 |
| 10 | 0 |
+-----+
10 rows in set (0.00 sec)

```

You can refer to columns in the subject table (the table associated with the trigger) by using the aliases `OLD` and `NEW`. `OLD.col_name` refers to a column of an existing row before it is updated or deleted. `NEW.col_name` refers to the column of a new row to be inserted or an existing row after it is updated.

The `DEFINER` clause specifies the MySQL account to be used when checking access privileges at trigger activation time. If a `user` value is given, it should be a MySQL account in `'user_name'@'host_name'` format (the same format used in the `GRANT` statement). The `user_name` and `host_name` values both are required. `CURRENT_USER` also can be given as `CURRENT_USER()`. The default `DEFINER` value is the user who executes the `CREATE TRIGGER` statement. (This is the same as `DEFINER = CURRENT_USER`.)

If you specify the `DEFINER` clause, you cannot set the value to any account but your own unless you have the `SUPER` privilege. These rules determine the legal `DEFINER` user values:

- If you do not have the `SUPER` privilege, the only legal `user` value is your own account, either specified literally or by using `CURRENT_USER`. You cannot set the definer to some other account.
- If you have the `SUPER` privilege, you can specify any syntactically legal account name. If the account does not actually exist, a warning is generated.

Although it is possible to create triggers with a non-existent `DEFINER` value, it is not a good idea for such triggers to be activated until the definer actually does exist. Otherwise, the behavior with re-

spect to privilege checking is undefined.

Note: Prior to MySQL 5.1.6, MySQL requires the `SUPER` privilege for the use of `CREATE TRIGGER`, so only the second of the preceding rules applies. As of 5.1.6, `CREATE TRIGGER` requires the `TRIGGER` privilege and `SUPER` is required only to be able to set `DEFINER` to a value other than your own account.

MySQL checks trigger privileges like this:

- At `CREATE TRIGGER` time, the user that issues the statement must have the `TRIGGER` privilege. (`SUPER` prior to MySQL 5.1.6.)
- At trigger activation time, privileges are checked against the `DEFINER` user. This user must have these privileges:
 - The `TRIGGER` privilege. (`SUPER` prior to MySQL 5.1.6.)
 - The `SELECT` privilege for the subject table if references to table columns occur via `OLD.col_name` or `NEW.col_name` in the trigger definition.
 - The `UPDATE` privilege for the subject table if table columns are targets of `SET NEW.col_name = value` assignments in the trigger definition.
 - Whatever other privileges normally are required for the statements executed by the trigger.

19.2. DROP TRIGGER Syntax

```
DROP TRIGGER [schema_name.]trigger_name
```

This statement drops a trigger. The schema (database) name is optional. If the schema is omitted, the trigger is dropped from the default schema. `DROP TRIGGER` was added in MySQL 5.0.2. Its use requires the `TRIGGER` privilege for the table associated with the trigger. (This statement requires the `SUPER` privilege prior to MySQL 5.1.6.)

Note: When upgrading from a version of MySQL older than MySQL 5.0.10 to 5.0.10 or newer — including all MySQL 5.1 releases — you must drop all triggers *before upgrading* and re-create them afterward, or else `DROP TRIGGER` does not work after the upgrade. See [Section 2.11.1, “Upgrading from MySQL 5.0 to 5.1”](#), for a suggested upgrade procedure.

19.3. Using Triggers

This section discusses how to use triggers in MySQL 5.1 and some limitations regarding their use. Additional information about trigger limitations is given in [Section I.1, “Restrictions on Stored Routines and Triggers”](#).

A trigger is a named database object that is associated with a table, and that activates when a particular event occurs for the table. Some uses for triggers are to perform checks of values to be inserted into a table or to perform calculations on values involved in an update.

A trigger is associated with a table and is defined to activate when an `INSERT`, `DELETE`, or `UPDATE` statement for the table executes. A trigger can be set to activate either before or after the triggering statement. For example, you can have a trigger activate before each row that is deleted from a table or after each row that is updated.

To create a trigger or drop a trigger, use the `CREATE TRIGGER` or `DROP TRIGGER` statement. The syntax for these statements is described in [Section 19.1, “CREATE TRIGGER Syntax”](#), and [Section 19.2, “DROP TRIGGER Syntax”](#).

Here is a simple example that associates a trigger with a table for `INSERT` statements. It acts as an accumulator to sum the values inserted into one of the columns of the table.

The following statements create a table and a trigger for it:

```
mysql> CREATE TABLE account (acct_num INT, amount DECIMAL(10,2));
mysql> CREATE TRIGGER ins_sum BEFORE INSERT ON account
-> FOR EACH ROW SET @sum = @sum + NEW.amount;
```

The `CREATE TRIGGER` statement creates a trigger named `ins_sum` that is associated with the `account` table. It also includes clauses that specify the trigger activation time, the triggering event, and what to do with the trigger activates:

- The keyword `BEFORE` indicates the trigger action time. In this case, the trigger should activate before each row inserted into the table. The other allowable keyword here is `AFTER`.
- The keyword `INSERT` indicates the event that activates the trigger. In the example, `INSERT` statements cause trigger activation. You can also create triggers for `DELETE` and `UPDATE` statements.
- The statement following `FOR EACH ROW` defines the statement to execute each time the trigger activates, which occurs once for each row affected by the triggering statement. In the example, the triggered statement is a simple `SET` that accumulates the values inserted into the `amount` column. The statement refers to the column as `NEW.amount` which means “the value of the `amount` column to be inserted into the new row.”

To use the trigger, set the accumulator variable to zero, execute an `INSERT` statement, and then see what value the variable has afterward:

```
mysql> SET @sum = 0;
mysql> INSERT INTO account VALUES(137,14.98),(141,1937.50),(97,-100.00);
mysql> SELECT @sum AS 'Total amount inserted';
+-----+
| Total amount inserted |
+-----+
| 1852.48                |
+-----+
```

In this case, the value of `@sum` after the `INSERT` statement has executed is $14.98 + 1937.50 - 100$, or `1852.48`.

To destroy the trigger, use a `DROP TRIGGER` statement. You must specify the schema name if the trigger is not in the default schema:

```
mysql> DROP TRIGGER test.ins_sum;
```

Trigger names exist in the schema namespace, meaning that all triggers must have unique names within a schema. Triggers in different schemas can have the same name.

In addition to the requirement that trigger names be unique for a schema, there are other limitations on the types of triggers you can create. In particular, you cannot have two triggers for a table that have the same activation time and activation event. For example, you cannot define two `BEFORE INSERT` triggers or two `AFTER UPDATE` triggers for a table. This should rarely be a significant limitation, because it is possible to define a trigger that executes multiple statements by using the `BEGIN ... END` compound statement construct after `FOR EACH ROW`. (An example appears later in this section.)

The `OLD` and `NEW` keywords enable you to access columns in the rows affected by a trigger. (`OLD` and `NEW` are not case sensitive.) In an `INSERT` trigger, only `NEW.col_name` can be used; there is no old row. In a `DELETE` trigger, only `OLD.col_name` can be used; there is no new row. In an `UPDATE` trigger, you can use `OLD.col_name` to refer to the columns of a row before it is updated and `NEW.col_name` to refer to the columns of the row after it is updated.

A column named with `OLD` is read-only. You can refer to it (if you have the `SELECT` privilege), but not modify it. A column named with `NEW` can be referred to if you have the `SELECT` privilege for it. In a `BEFORE` trigger, you can also change its value with `SET NEW.col_name = value` if you have the `UPDATE` privilege for it. This means you can use a trigger to modify the values to be inserted into a new row or that are used to update a row.

In a `BEFORE` trigger, the `NEW` value for an `AUTO_INCREMENT` column is 0, not the automatically generated sequence number that will be generated when the new record actually is inserted.

`OLD` and `NEW` are MySQL extensions to triggers.

By using the `BEGIN ... END` construct, you can define a trigger that executes multiple statements. Within the `BEGIN` block, you also can use other syntax that is allowed within stored routines such as conditionals and loops. However, just as for stored routines, if you use the `mysql` program to define a trigger that executes multiple statements, it is necessary to redefine the `mysql` statement delimiter so that you can use the `;` statement delimiter within the trigger definition. The following example illustrates these points. It defines an `UPDATE` trigger that checks the new value to be used for updating each row, and modifies the value to be within the range from 0 to 100. This must be a `BEFORE` trigger because the value needs to be checked before it is used to update the row:

```
mysql> delimiter //
mysql> CREATE TRIGGER upd_check BEFORE UPDATE ON account
-> FOR EACH ROW
-> BEGIN
->     IF NEW.amount < 0 THEN
->         SET NEW.amount = 0;
->     ELSEIF NEW.amount > 100 THEN
->         SET NEW.amount = 100;
->     END IF;
-> END; //
mysql> delimiter ;
```

It can be easier to define a stored procedure separately and then invoke it from the trigger using a simple `CALL` statement. This is also advantageous if you want to invoke the same routine from within several triggers.

There are some limitations on what can appear in statements that a trigger executes when activated:

- The trigger cannot use the `CALL` statement to invoke stored procedures that return data to the client or that use dynamic SQL. (Stored procedures are allowed to return data to the trigger through `OUT` or `INOUT` parameters.)
- The trigger cannot use statements that explicitly or implicitly begin or end a transaction such as `START TRANSACTION`, `COMMIT`, or `ROLLBACK`.

MySQL handles errors during trigger execution as follows:

- If a `BEFORE` trigger fails, the operation on the corresponding row is not performed.
- A `BEFORE` trigger is activated by the *attempt* to insert or modify the row, regardless of whether the attempt subsequently succeeds.

- An **AFTER** trigger is executed only if the **BEFORE** trigger (if any) and the row operation both execute successfully.
- An error during either a **BEFORE** or **AFTER** trigger results in failure of the entire statement that caused trigger invocation.
- For transactional tables, failure of a statement should cause rollback of all changes performed by the statement. Failure of a trigger causes the statement to fail, so trigger failure also causes rollback. For non-transactional tables, such rollback cannot be done, so although the statement fails, any changes performed prior to the point of the error remain in effect.

Chapter 20. Event Scheduler

This chapter describes the *MySQL Event Scheduler*, for which support was added in MySQL 5.1.6, and is divided into the following sections:

- [Section 20.1, “Event Scheduler Overview”](#) provides an introduction to and conceptual overview of MySQL Events.
- [Section 20.2, “Event Scheduler Syntax”](#) discusses the SQL commands introduced in MySQL 5.1.6 for creating, altering, and dropping MySQL Events.
- [Section 20.3, “Event Metadata”](#) shows how to obtain information about events and how this information is stored by the MySQL Server.
- [Section 20.5, “The Event Scheduler and MySQL Privileges”](#) discusses the privileges required to work with events and the ramifications that events have with regard to privileges when executing.
- [Section 20.6, “Event Scheduler Limitations and Restrictions”](#) describes the restrictions and limitations of MySQL's Event Scheduler implementation.

Additional Resources:

- You may find the [MySQL Event Scheduler User Forum](http://forums.mysql.com/list.php?119) [http://forums.mysql.com/list.php?119] of use when working with events. Here you can discuss the MySQL Event Scheduler with other MySQL users and the MySQL developers.

20.1. Event Scheduler Overview

MySQL Events are tasks that run according to a schedule. Therefore, we sometimes refer to them as *scheduled* events. When you create an event, you are creating a named database object containing one or more SQL statements to be executed at one or more regular intervals, beginning and ending at a specific date and time. Conceptually, this is similar to the idea of the Unix [crontab](#) (also known as a “cron job”) or the Windows Task Scheduler.

Scheduled tasks of this type are also sometimes known as “temporal triggers”, implying that these are objects that are triggered by the passage of time. While this is essentially correct, we prefer to use the term *events* in order to avoid confusion with triggers of the type discussed in [Chapter 19, Triggers](#). Events should more specifically not be confused with “temporary triggers”. Whereas a trigger is a database object whose statements are executed in response to a specific type of event that occurs on a given table, a (scheduled) event is an object whose statements are executed in response to the passage of a specified time interval.

While there is no provision in the SQL Standard for event scheduling, there are precedents in other database systems, and you may notice some similarities between these implementations and that found in the MySQL Server.

MySQL Events have the following major features and properties:

- In MySQL 5.1.12 and later, an event is uniquely identified by its name and the schema to which it is assigned. (Previously, an event was also unique to its definer.)
- An event performs a specific action according to a schedule. This action consists of an SQL state-

ment, which can be a compound statement in a `BEGIN . . . END` block if desired (see [Section 18.2.5, “BEGIN . . . END Compound Statement Syntax”](#)). An event's timing can be either *one-time* or *recurrent*. A one-time event executes one time only. A recurrent event repeats its action at a regular interval, and the schedule for a recurring event can be assigned a specific start day and time, end day and time, both, or neither. (By default, a recurring event's schedule begins as soon as it is created, and continues indefinitely, until it is disabled or dropped.)

- Users can create, modify, and drop scheduled events using SQL statements intended for these purposes. Syntactically invalid event creation and modification statements fail with an appropriate error message. *A user may include statements in an event's action which require privileges that the user does not actually have.* The event creation or modification statement succeeds but the event's action fails. See [Section 20.5, “The Event Scheduler and MySQL Privileges”](#) for details.
- Many of the properties of an event can be set or modified using SQL statements. These properties include the event's name, timing, persistence (that is, whether it is preserved following the expiration of its schedule), status (enabled or disabled), action to be performed, and the schema to which it is assigned. See [Section 20.2.2, “ALTER EVENT Syntax”](#).

The definer of an event is the user who created the event, unless the event has been altered, in which case the definer is the user who issued the last `ALTER EVENT` statement effecting that event. An event can be modified by any user having the `EVENT` privilege on the database for which the event is defined. (Prior to MySQL 5.1.12, only an event's definer, or a user having privileges on the `mysql.event` table, could modify a given event.) See [Section 20.5, “The Event Scheduler and MySQL Privileges”](#).

- An event's action statement may include most SQL statements permitted within stored routines.

Events are executed by a special *event scheduler thread*; when we refer to the Event Scheduler, we actually refer to this thread. When running, the event scheduler thread and its current state can be seen by users having the `SUPER` privilege in the output of `SHOW PROCESSLIST`, as shown in the discussion that follows.

The global variable `event_scheduler` determines whether the Event Scheduler is enabled and running on the server. Beginning with MySQL 5.1.12, it has one of these 3 values, which affect event scheduling as described here:

- **OFF:** The Event Scheduler is stopped. The event scheduler thread does not run, is not shown in the output of `SHOW PROCESSLIST`, and no scheduled events are executed. `OFF` is the default value for `event_scheduler`.

When the Event Scheduler is stopped (`event_scheduler` is `OFF`), it can be started by setting the value of `event_scheduler` to `ON`. (See next item.)

- **ON:** The Event Scheduler is started; the event scheduler thread runs and executes all scheduled events.

When the Event Scheduler is `ON`, the event scheduler thread is listed in the output of `SHOW PROCESSLIST` as a daemon process, and its state is represented as shown here:

```
mysql> SHOW PROCESSLIST\G
***** 1. row *****
  Id: 1
  User: root
  Host: localhost
  db: NULL
Command: Query
  Time: 0
  State: NULL
  Info: show processlist
***** 2. row *****
```

```

    Id: 2
    User: event_scheduler
    Host: localhost
    db: NULL
    Command: Daemon
    Time: 3
    State: Waiting for next activation
    Info: NULL
2 rows in set (0.00 sec)

```

Event scheduling can be stopped by setting the value of `event_scheduler` to `OFF`.

- **DISABLED**: This value renders the Event Scheduler non-operational. When the Event Scheduler is **DISABLED**, the event scheduler thread does not run (and so does not appear in the output of `SHOW PROCESSLIST`).

When the server is running `event_scheduler` can be toggled between `ON` and `OFF` (using `SET`). It is also possible to use `0` for `OFF`, and `1` for `ON` when setting this variable. Thus, any of the following 4 statements can be used in the `mysql` client to turn on the Event Scheduler:

```

SET GLOBAL event_scheduler = ON;
SET @@global.event_scheduler = ON;
SET GLOBAL event_scheduler = 1;
SET @@global.event_scheduler = 1;

```

Similarly, any of these 4 statements can be used to turn off the Event Scheduler:

```

SET GLOBAL event_scheduler = OFF;
SET @@global.event_scheduler = OFF;
SET GLOBAL event_scheduler = 0;
SET @@global.event_scheduler = 0;

```

Although `ON` and `OFF` have numeric equivalents, the value displayed for `event_scheduler` by `SELECT` or `SHOW VARIABLES` is always one of `OFF`, `ON`, or `DISABLED`. *DISABLED has no numeric equivalent*. For this reason, `ON` and `OFF` are usually preferred over `1` and `0` when setting this variable.

Note that attempting to set `event_scheduler` without specifying it as a global variable causes an error:

```

mysql> SET @@event_scheduler = OFF;
ERROR 1229 (HY000): Variable 'event_scheduler' is a GLOBAL
variable and should be set with SET GLOBAL

```

Important: It is not possible to enable or disable the Event Scheduler when the server is running. That is, you can change the value of `event_scheduler` to `DISABLED` — or from `DISABLED` to one of the other permitted values for this option — only when the server is stopped. Attempting to do so when the server is running fails with an error.

To disable the event scheduler, use one of the following two methods:

- As a command-line option when starting the server:

```
--event-scheduler=DISABLED
```

- In the server configuration file (`my.cnf`, or `my.ini` on Windows systems), include the line where it will be read by the server (for example, in a `[mysqld]` section):

```
event_scheduler=DISABLED
```

To enable the Event Scheduler, restart the server without the `--event-scheduler=DISABLED` command line option, or after removing or commenting out the line containing `event_scheduler=DISABLED` in the server configuration file, as appropriate. Alternatively, you can use `ON` (or `1`) or `OFF` (or `0`) in place of the `DISABLED` value when starting the server.

Note: You can issue event-manipulation statements when `event_scheduler` is set to `DISABLED`. No warnings or errors are generated in such cases (provided that the statements are themselves valid). However, scheduled events cannot execute until this variable is set to `ON` (or `1`). Once this has been done, the event scheduler thread executes all events whose scheduling conditions are satisfied.

In MySQL 5.1.11, `event_scheduler` behaved as follows: this variable could take one of the values `0` (or `OFF`), `1` (or `ON`), or `2`. Setting it to `0` turned event scheduling off, so that the event scheduler thread did not run; the `event_scheduler` variable could not be set to this value while the server was running. Setting it to `1` so that the event scheduler thread ran and executed scheduled events. In this state, the event scheduler thread appeared to be sleeping when viewed with `SHOW PROCESSLIST`. When `event_scheduler` was set to `2` (which was the default value), the Event Scheduler was considered to be “suspended”; the event scheduler thread ran and could be seen in the output of `SHOW PROCESSLIST` (where `Suspended` was displayed in the `State` column), but did not execute any scheduled events. The value of `event_scheduler` could be changed only between `1` (or `ON`) and `2` while the server was running. Setting it to `0` (or `OFF`) required a server restart, as did changing its value from `0` (or `OFF`) to `1` (or `ON`) or `2`.

Prior to MySQL 5.1.11, `event_scheduler` could take one of only the 2 values `0|OFF` or `1|ON`, and the default value was `0|OFF`. It was also possible to start and stop the event scheduler thread while the MySQL server was running.

For more information concerning the reasons for these changes in behaviour, see [Bug#17619](http://bugs.mysql.com/17619) [<http://bugs.mysql.com/17619>].

For SQL statements used to create, alter, and drop events, see [Section 20.2, “Event Scheduler Syntax”](#).

MySQL 5.1.6 and later provides an `EVENTS` table in the `INFORMATION_SCHEMA` database. This table can be queried to obtain information about scheduled events which have been defined on the server. See [Section 20.3, “Event Metadata”](#), and [Section 22.20, “The INFORMATION_SCHEMA EVENTS Table”](#), for more information.

For information regarding event scheduling and the MySQL privilege system, see [Section 20.5, “The Event Scheduler and MySQL Privileges”](#).

20.2. Event Scheduler Syntax

MySQL 5.1.6 and later provides several SQL statements for working with scheduled events:

- New events are defined using the `CREATE EVENT` statement. See [Section 20.2.1, “CREATE EVENT Syntax”](#).
- The definition of an existing event can be changed by means of the `ALTER EVENT` statement. See [Section 20.2.2, “ALTER EVENT Syntax”](#).
- When a scheduled event is no longer wanted or needed, it can be deleted from the server by its definer using the `DROP EVENT` statement. See [Section 20.2.3, “DROP EVENT Syntax”](#). (Whether an event persists past the end of its schedule also depends on its `ON COMPLETION` clause, if it has one. See [Section 20.2.1, “CREATE EVENT Syntax”](#).)

An event can be deleted by any user having the `EVENT` privilege for the database on which the event is defined. Prior to MySQL 5.12, a user other than the definer required privileges on the `mysql.event` table. See [Section 20.5, “The Event Scheduler and MySQL Privileges”](#).

20.2.1. CREATE EVENT Syntax

```
CREATE EVENT [IF NOT EXISTS] event_name
ON SCHEDULE schedule
[ON COMPLETION [NOT] PRESERVE]
[ENABLE | DISABLE]
[COMMENT 'comment']
DO sql_statement;

schedule:
  AT timestamp [+ INTERVAL interval]
  | EVERY interval [STARTS timestamp] [ENDS timestamp]

interval:
  quantity {YEAR | QUARTER | MONTH | DAY | HOUR | MINUTE |
             WEEK | SECOND | YEAR_MONTH | DAY_HOUR | DAY_MINUTE |
             DAY_SECOND | HOUR_MINUTE | HOUR_SECOND | MINUTE_SECOND}
```

This statement creates and schedules a new event. The minimum requirements for a valid `CREATE EVENT` statement are as follows:

- The keywords `CREATE EVENT` plus an event name, which uniquely identifies the event in the current schema.
(Prior to MySQL 5.1.12, the event name needed to be unique only among events created by the same user on a given database.)
- An `ON SCHEDULE` clause, which determines when and how often the event executes.
- A `DO` clause, which contains the SQL statement to be executed by an event.

This is an example of a minimal `CREATE EVENT` statement:

```
CREATE EVENT myevent
ON SCHEDULE AT CURRENT_TIMESTAMP + INTERVAL 1 HOUR
DO
  UPDATE myschema.mytable SET mycol = mycol + 1;
```

The previous statement creates an event named `myevent`. This event executes once — one hour following its creation — by running an SQL statement that increments the value of the `myschema.mytable` table's `mycol` column by 1.

The `event_name` must be a valid MySQL identifier with a maximum length of 64 characters. It may be delimited using back ticks, and may be qualified with the name of a database schema. An event is associated with both a MySQL user (the definer) and a schema, and its name must be unique among names of events within that schema. In general, the rules governing event names are the same as those for names of stored routines. See [Section 9.2, “Database, Table, Index, Column, and Alias Names”](#).

If no schema is indicated as part of `event_name`, then the default (current) schema is assumed. The definer is always the current MySQL user.

(Prior to MySQL 5.1.12, it was possible for two different users to create different events having the same name on the same database schema.)

Note: MySQL uses case-insensitive comparisons when checking for the uniqueness of event names. This means that, for example, you cannot have two events named `myevent` and `MyEvent` in the same database schema.

`IF NOT EXISTS` functions in the much the same fashion with `CREATE EVENT` as it does when used with a `CREATE TABLE` statement; if an event named `event_name` already exists in the same schema, no action is taken, and no error results. (However, a warning is generated.)

The `ON SCHEDULE` clause determines when, how often, and for how long the `sql_statement` defined for the event repeats. This clause takes one of two forms:

- `AT timestamp` is used for a one-time event. It specifies that the event executes one time only at the date and time, given as the `timestamp`, which must include both the date and time, or must be an expression that resolves to a datetime value. You may use a value which is of either the `DATE-TIME` or `TIMESTAMP` type for this purpose. The `timestamp` must also be in the future — you cannot schedule an event to take place in the past. Trying to do so fails with an error, as shown here:

```
mysql> SELECT NOW();
+-----+
| NOW() |
+-----+
| 2006-02-10 23:59:01 |
+-----+
1 row in set (0.04 sec)

mysql> CREATE EVENT e_totals
-> ON SCHEDULE AT '2006-02-10 23:59:00'
-> DO INSERT INTO test.totals VALUES (NOW());
ERROR 1522 (HY000): Activation (AT) time is in the past
```

`CREATE EVENT` statements which are themselves invalid — for whatever reason — fail with an error.

You may use `CURRENT_TIMESTAMP` to specify the current date and time. In such a case, the event acts as soon as it is created.

In order to create an event which occurs at some point in the future relative to the current date and time — such as that expressed by the phrase “three weeks from now” — you can use the optional clause `+ INTERVAL interval`. The `interval` portion consists of two parts, a quantity and a unit of time, and follows the same syntax rules that govern intervals used in the `DATE_ADD()` function (see [Section 12.5, “Date and Time Functions”](#)). The units keywords are also the same, except that you cannot use any units involving microseconds when defining an event.

You can also combine intervals. For example, `AT CURRENT_TIMESTAMP + INTERVAL 3 WEEK + INTERVAL 2 DAY` is equivalent to “three weeks and two days from now”. Each portion of such a clause must begin with `+ INTERVAL`.

- For actions which are to be repeated at a regular interval, you can use an `EVERY` clause. The `EVERY` keyword is followed by an `interval` as described in the previous discussion of the `AT` keyword. (`+ INTERVAL` is *not* used with `EVERY`.) For example, `EVERY 6 WEEK` means “every six weeks”.

It is not possible to combine `+ INTERVAL` clauses in a single `EVERY` clause; however, you can use the same complex time units allowed in a `+ INTERVAL`. For example, “every two minutes and ten seconds” can be expressed as `EVERY '2:10' MINUTE_SECOND`.

An `EVERY` clause may also contain an optional `STARTS` clause. `STARTS` is followed by a `timestamp` value which indicates when the action should begin repeating, and may also use `+ INTERVAL interval` in order to specify an amount of time “from now”. For example, `EVERY 3 MONTH STARTS CURRENT_TIMESTAMP + 1 WEEK` means “every three months, beginning one week from now”. Similarly, you can express “every two weeks, beginning six hours and fifteen minutes from now” as `EVERY 2 WEEK STARTS CURRENT_TIMESTAMP + '6:15' HOUR_MINUTE`. Not specifying `STARTS` is the same as using `STARTS CURRENT_TIMESTAMP` — that is, the action specified for the event begins repeating immediately upon creation of the event.

An `EVERY` clause may also contain an optional `ENDS` clause. The `ENDS` keyword is followed by a `timestamp` value which tells MySQL when the event should stop repeating. You may also use `+ INTERVAL interval` with `ENDS`; for instance, `EVERY 12 HOUR STARTS CURRENT_TIMESTAMP + INTERVAL 30 MINUTE ENDS CURRENT_TIMESTAMP + INTER-`

`VAL 4 WEEK` is equivalent to “every twelve hours, beginning thirty minutes from now, and ending four weeks from now”. Not using `ENDS` means that the event continues executing indefinitely.

`ENDS` supports the same syntax for complex time units as `STARTS` does.

You may use `STARTS`, `ENDS`, both, or neither in an `EVERY` clause.

Note: Where `STARTS` or `ENDS` is given as a datetime value, it is taken to mean local time on the server. However, the values for both of these are currently reported using Universal Time in the `INFORMATION_SCHEMA.EVENTS` and `mysql.event` tables, as well as in the output from `SHOW EVENTS`. This is not intended behaviour and your application should not rely on it, as it is subject to change ([Bug#16420](http://bugs.mysql.com/16420) [<http://bugs.mysql.com/16420>]). For additional information, see [Section 22.20](#), “The `INFORMATION_SCHEMA.EVENTS` Table”.

The `ON SCHEDULE` clause may not use subselects. This is true for both `CREATE EVENT` and `ALTER EVENT` statements.

Normally, once an event has expired, it is immediately dropped. You can override this behavior by specifying `ON COMPLETION PRESERVE`. Using `ON COMPLETION NOT PRESERVE` merely makes the default non-persistent behavior explicit.

You can create an event but keep it from being active using the `DISABLE` keyword. Alternatively, you may use `ENABLE` to make explicit the default status, which is active. This is most useful in conjunction with `ALTER EVENT` (see [Section 20.2.2](#), “`ALTER EVENT Syntax`”).

You may supply a comment for an event using a `COMMENT` clause. *comment* may be any string of up to 64 characters that you wish to use for describing the event. The comment text, being a string literal, must be surrounded by quotation marks.

The `DO` clause specifies an action carried by the event, and consists of an SQL statement. Nearly any valid MySQL statement which can be used in a stored routine can also be used as the action statement for a scheduled event. (See [Section I.1](#), “Restrictions on Stored Routines and Triggers”.) For example, the following event `e_hourly` deletes all rows from the `sessions` table once per hour, where this table is part of the `site_activity` schema:

```
CREATE EVENT e_hourly
ON SCHEDULE
  EVERY 1 HOUR
  COMMENT 'Clears out sessions table each hour.'
DO
  DELETE FROM site_activity.sessions;
```

Note: The `SHOW` statement and `SELECT` statements that merely return a result set have no effect when used in an event; the output from these is not sent to the MySQL Monitor, nor is it stored anywhere. However, you can use statements such as `SELECT INTO` and `INSERT ... SELECT` that store a result. (See the next example in this section for an instance of the latter.)

Any reference in the `DO` clause to a table in other than the same database schema to which the event belongs must be qualified with the name of the schema in which the table occurs. (In MySQL 5.1.6, all tables referenced in event `DO` clauses had to include a reference to the database.)

As with stored routines, you can use multiple statements in the `DO` clause by bracketing them with the `BEGIN` and `END` keywords, as shown here:

```
DELIMITER |
CREATE EVENT e_daily
ON SCHEDULE
  EVERY 1 DAY
  COMMENT 'Saves total number of sessions then clears the table each day.'
DO
```

```

BEGIN
  INSERT INTO site_activity.totals (when, total)
    SELECT CURRENT_TIMESTAMP, COUNT(*)
      FROM site_activity.sessions;
  DELETE FROM site_activity.sessions;
END |
DELIMITER ;

```

Note the use of the `DELIMITER` statement to change the statement delimiter, as with stored routines. See [Section 18.2.1, “CREATE PROCEDURE and CREATE FUNCTION Syntax”](#).

More complex compound statements, such as those used in stored routines, are possible in an event. This example uses local variables, an error handler, and a flow control construct:

```

DELIMITER |
CREATE EVENT e
  ON SCHEDULE
    EVERY 5 SECOND
  DO
    BEGIN
      DECLARE v INTEGER;
      DECLARE CONTINUE HANDLER FOR SQLEXCEPTION BEGIN END;

      SET v = 0;

      WHILE v < 5 DO
        INSERT INTO t1 VALUES (0);
        UPDATE t2 SET s1 = s1 + 1;
        SET v = v + 1;
      END WHILE;
    END |
DELIMITER ;

```

There is no way to pass parameters directly to or from events; however, it is possible to invoke a stored routine with parameters:

```

CREATE EVENT e_call_myproc
  ON SCHEDULE
    AT CURRENT_TIMESTAMP + 1 DAY
  DO CALL myproc(5, 27);

```

In addition, if the event's definer has the `SUPER` privilege, that event may read and write global variables. As granting this privilege entails a potential for abuse, extreme care must be taken in doing so.

Generally, any statements which are valid in stored routines may be used for action statements executed by events. For more information about statements allowable within stored routines, see [Section 18.2, “Stored Routine Syntax”](#). You can create an event as part of a stored routine, but an event cannot be created by another event.

20.2.2. ALTER EVENT Syntax

```

ALTER EVENT event_name
  [ON SCHEDULE schedule]
  [RENAME TO new_event_name]
  [ON COMPLETION [NOT] PRESERVE]
  [COMMENT 'comment']
  [ENABLE | DISABLE]
  [DO sql_statement]

```

The `ALTER EVENT` statement is used to change one or more of the characteristics of an existing event without the need to drop and recreate it. The syntax for each of the `ON SCHEDULE`, `ON COMPLETION`, `COMMENT`, `ENABLE / DISABLE`, and `DO` clauses is exactly the same as when used with `CREATE EVENT`. (See [Section 20.2.1, “CREATE EVENT Syntax”](#).)

Beginning with MySQL 5.1.12, any user can alter an event defined on a database for which that user has the `EVENT` privilege. When a user executes a successful `ALTER EVENT` statement, that user becomes the definer for the effected event.

(In MySQL 5.1.11 and earlier, an event could be altered only by its definer, or by a user having the `SUPER` privilege.)

`ALTER EVENT` works only with an existing event:

```
mysql> ALTER EVENT no_such_event
>     ON SCHEDULE
>     EVERY '2:3' DAY_HOUR;
ERROR 1517 (HY000): Unknown event 'no_such_event'
```

In each of the following examples, assume that the event named `myevent` is defined as shown here:

```
CREATE EVENT myevent
ON SCHEDULE
  EVERY 6 HOUR
  COMMENT 'A sample comment.'
DO
  UPDATE myschema.mytable SET mycol = mycol + 1;
```

The following statement changes the schedule for `myevent` from once every six hours starting immediately to once every twelve hours, starting four hours from the time the statement is run:

```
ALTER EVENT myevent
ON SCHEDULE
  EVERY 12 HOUR
  STARTS CURRENT_TIMESTAMP + 4 HOUR;
```

To disable `myevent`, use this `ALTER EVENT` statement:

```
ALTER EVENT myevent
DISABLE;
```

It is possible to change multiple characteristics of an event in a single statement. This example changes the SQL statement executed by `myevent` to one that deletes all records from `mytable`; it also changes the schedule for the event such that it executes once, one day after this `ALTER EVENT` statement is run.

```
ALTER TABLE myevent
ON SCHEDULE
  AT CURRENT_TIMESTAMP + INTERVAL 1 DAY
DO
  TRUNCATE TABLE myschema.mytable;
```

To rename an event, use the `ALTER EVENT` statement's `RENAME TO` clause, as shown here:

```
ALTER EVENT myevent
RENAME TO yourevent;
```

The previous statement renames the event `myevent` to `yourevent`. (**Note:** There is no `RENAME EVENT` statement.)

You can also move an event to a different schema using `ALTER EVENT ... RENAME TO ...` and `schema_name.table_name` notation, as shown here:

```
ALTER EVENT oldschema.myevent
RENAME TO newschema.myevent;
```

In order to execute the previous statement, the user executing it must have the `EVENT` privilege on both

the `oldschema` and `newschema` database schemas.

It is necessary to include only those options in an `ALTER EVENT` statement which correspond to characteristics that you actually wish to change; options which are omitted retain their existing values. This includes any default values for `CREATE EVENT` such as `ENABLE`.

20.2.3. DROP EVENT Syntax

```
DROP EVENT [IF EXISTS] event_name
```

This statement drops the event named `event_name`. The event immediately ceases being active, and is deleted completely from the server.

If the event does not exist, the error `ERROR 1517 (HY000): Unknown event 'event_name'` results. You can override this and cause the statement to fail silently by using `IF EXISTS`.

Beginning with MySQL 5.1.12, an event can be dropped by any user having the `EVENT` privilege on the database schema to which the event to be dropped belongs. (In MySQL 5.1.11 and earlier, an event could be dropped only by its definer, or by a user having the `SUPER` privilege.)

20.3. Event Metadata

Information about events can be obtained as follows:

- Querying the `EVENTS` table of the `INFORMATION_SCHEMA` database. See [Section 22.20, “The INFORMATION_SCHEMA EVENTS Table”](#).
- Using the `SHOW EVENTS` statement. See [Section 13.5.4.15, “SHOW EVENTS”](#).
- Using the `SHOW CREATE EVENT` statement. See [Section 13.5.4.7, “SHOW CREATE EVENT”](#).
- A record of events executed on the server can be read from the MySQL Server's error log (see [Section 20.5, “The Event Scheduler and MySQL Privileges”](#) for an example).

20.4. Event Scheduler Status

Information about the state of the Event Scheduler for debugging and troubleshooting purposes can be obtained as follows:

- In MySQL 5.1.11 `-debug` builds, you can use the `SHOW SCHEDULER STATUS` statement; see [Section 13.5.4.24, “SHOW SCHEDULER STATUS Syntax”](#).

Important: This statement was removed in MySQL 5.1.12. We intend to implement an SQL statement providing similar functionality in a future MySQL release.

- Beginning with MySQL 5.1.12, event scheduler status information can be obtained by running the `mysqladmin debug` (see [Section 8.8, “mysqladmin — Client for Administering a MySQL Server”](#)); after running this command, the error log contains output relating to the Event Scheduler, similar to what is shown here:

```
Events status:
LLA = Last Locked At   LUA = Last Unlocked At
WOC = Waiting On Condition  DL = Data Locked

Event scheduler status:
State      : INITIALIZED
Thread id  : 0
```

```

LLA      : init_scheduler:313
LUA      : init_scheduler:318
WOC      : NO
Workers  : 0
Executed  : 0
Data locked: NO

Event queue status:
Element count : 1
Data locked   : NO
Attempting lock : NO
LLA          : init_queue:148
LUA          : init_queue:168
WOC          : NO
Next activation : 0000-00-00 00:00:00

```

20.5. The Event Scheduler and MySQL Privileges

To enable or disable the execution of scheduled events, it is necessary to set the value of the global `event_scheduler` variable. This requires the `SUPER` privilege.

MySQL 5.1.6 introduces a privilege governing the creation, modification, and deletion of events, the `EVENT` privilege. This privilege can be bestowed using `GRANT`. For example, this `GRANT` statement confers the `EVENT` privilege for the schema named `myschema` on the user `jon@ghidora`:

```
GRANT EVENT ON myschema.* TO jon@ghidora;
```

(We assume that this user account already exists, and that we wish for it to remain unchanged otherwise.)

To grant this same user the `EVENT` privilege on all schemas would require the following statement:

```
GRANT EVENT ON *.* TO jon@ghidora;
```

The `EVENT` privilege has schema-level scope. Therefore, trying to grant it on a single table results in an error as shown:

```
mysql> GRANT EVENT ON myschema.mytable TO jon@ghidora;
ERROR 1144 (42000): Illegal GRANT/REVOKE command; please
consult the manual to see which privileges can be used
```

It is important to understand that an event is executed with the privileges of its definer, and that it cannot perform any actions for which its definer does not have the requisite privileges. For example, suppose that `jon@ghidora` has the `EVENT` privilege for `myschema`. Suppose also that this user has the `SELECT` privilege for `myschema`, but no other privileges for this schema. It is possible for `jon@ghidora` to create a new event such as this one:

```
CREATE EVENT e_store_ts
ON SCHEDULE
  EVERY 10 SECOND
DO
  INSERT INTO myschema.mytable VALUES (UNIX_TIMESTAMP());
```

The user waits for a minute or so, and then performs a `SELECT * FROM mytable;` query, expecting to see several new rows in the table. Instead, he finds that the table is empty. Since he does not have the `INSERT` privilege for the table in question, the event has no effect.

If you inspect the MySQL error log (`hostname.err`), you can see that the event is executing, but the action it is attempting to perform fails, as indicated by `RetCode=0`:

```

060209 22:39:44 [Note] EVEX EXECUTING event newdb.e [EXPR:10]
060209 22:39:44 [Note] EVEX EXECUTED event newdb.e [EXPR:10]. RetCode=0
060209 22:39:54 [Note] EVEX EXECUTING event newdb.e [EXPR:10]
060209 22:39:54 [Note] EVEX EXECUTED event newdb.e [EXPR:10]. RetCode=0
060209 22:40:04 [Note] EVEX EXECUTING event newdb.e [EXPR:10]
060209 22:40:04 [Note] EVEX EXECUTED event newdb.e [EXPR:10]. RetCode=0

```

Since this user very likely does not have access to the error log, he can verify whether the event's action statement is valid by running it himself:

```

mysql> INSERT INTO myschema.mytable VALUES (UNIX_TIMESTAMP());
ERROR 1142 (42000): INSERT command denied to user
'jon'@'ghidora' for table 'mytable'

```

Inspection of the `INFORMATION_SCHEMA.EVENTS` table shows that `e_store_ts` exists and is enabled, but its `LAST_EXECUTED` column is `NULL`:

```

mysql> SELECT * FROM INFORMATION_SCHEMA.EVENTS
> WHERE EVENT_NAME='e_store_ts'
> AND EVENT_SCHEMA='myschema'\G
***** 1. row *****
EVENT_CATALOG: NULL
EVENT_SCHEMA: myschema
EVENT_NAME: e_store_ts
DEFINER: jon@ghidora
EVENT_BODY: SQL
EVENT_DEFINITION: INSERT INTO myschema.mytable VALUES (UNIX_TIMESTAMP())
EVENT_TYPE: RECURRING
EXECUTE_AT: NULL
INTERVAL_VALUE: 5
INTERVAL_FIELD: INTERVAL_SECOND
SQL_MODE: NULL
STARTS: 0000-00-00 00:00:00
ENDS: 0000-00-00 00:00:00
STATUS: ENABLED
ON_COMPLETION: NOT PRESERVE
CREATED: 2006-02-09 22:36:06
LAST_ALTERED: 2006-02-09 22:36:06
LAST_EXECUTED: NULL
EVENT_COMMENT:
1 row in set (0.00 sec)

```

(**Note:** Prior to MySQL 5.1.12, there was no `EVENT_DEFINITION` column, and `EVENT_BODY` contained the SQL statement or statements to be executed. See [Section 22.20, “The INFORMATION_SCHEMA EVENTS Table”](#), for more information.)

To rescind the `EVENT` privilege, use the `REVOKE` statement. In this example, the `EVENT` privilege on the schema `myschema` is removed from the `jon@ghidora` user account:

```

REVOKE EVENT ON myschema.* FROM jon@ghidora;

```

Important: Revoking the `EVENT` privilege from a user account does *not* delete or disable any events that may have been created by that account.

For example, suppose that that user `jon@ghidora` has been granted the `EVENT` and `INSERT` privileges on the `myschema` schema. This user then creates the following event:

```

CREATE EVENT e_insert
ON SCHEDULE
EVERY 7 SECOND
DO
INSERT INTO myschema.mytable;

```

After this event has been created, `root` revokes the `EVENT` privilege for `jon@ghidora`. However, `e_insert` continues to execute, inserting a new row into `mytable` each seven seconds.

Event definitions are stored in the `mysql.event` table, which was added in MySQL 5.1.6. To drop an event created by another user account, the MySQL `root` user (or another user with the necessary privileges) can delete rows from this table. For example, to remove the event `e_insert` shown previously, `root` can use the following statement:

```
DELETE FROM mysql.event
WHERE db = 'myschema'
  AND definer = 'jon@ghidora'
  AND name = 'e_insert';
```

It is very important to match the event name, database schema name, and user account when deleting rows from the `mysql.event` table. This is because the same user can create different events of the same name in different schemas.

Note: The namespace for scheduled events changed in MySQL 5.1.12. Prior to that MySQL version, different users could create different events having the same name in the same database; in MySQL 5.1.12 and later, that is no longer the case. When upgrading to MySQL 5.1.12 or later from MySQL 5.1.11 or earlier, it is extremely important to make sure that no events in the same database share the same name, *prior to performing the upgrade*.

Users' `EVENT` privileges are stored in the `Event_priv` columns of the `mysql.user` and `mysql.db` tables. In both cases, this column holds one of the values 'Y' or 'N'. 'N' is the default. `mysql.user.Event_priv` is set to 'Y' for a given user only if that user has the global `EVENT` privilege (that is, if the privilege was bestowed using `GRANT EVENT ON *.*`). For a schema-level `EVENT` privilege, `GRANT` creates a row in `mysql.db` and sets that row's `Db` column to the name of the schema, the `User` column to the name of the user, and the `Event_priv` column to 'Y'. There should never be any need to manipulate these tables directly, since the `GRANT EVENT` and `REVOKE EVENT` statements perform the required operations on them.

MySQL 5.1.6 introduces five status variables providing counts of event-related operations (but *not* of statements executed by events — see [Section 20.6, “Event Scheduler Limitations and Restrictions”](#)). These are:

- `Com_create_event`: The number of `CREATE EVENT` statements executed since the last server restart.
- `Com_alter_event`: The number of `ALTER EVENT` statements executed since the last server restart.
- `Com_drop_event`: The number of `DROP EVENT` statements executed since the last server restart.
- `Com_show_create_event`: The number of `SHOW CREATE EVENT` statements executed since the last server restart.
- `Com_show_events`: The number of `SHOW EVENTS` statements executed since the last server restart.

You can view current values for all of these at one time by running the statement `SHOW STATUS LIKE '%event%';`

20.6. Event Scheduler Limitations and Restrictions

This section lists restrictions and limitations applying to event scheduling in MySQL.

In MySQL 5.1.6, any table referenced in an event's action statement must be fully qualified with the

name of the schema in which it occurs (that is, as `schema_name.table_name`).

An event may not be created, altered, or dropped by a trigger, stored routine, or another event. An event also may not create, alter, or drop triggers or stored routines. (Bug#16409 [http://bugs.mysql.com/16409], Bug#18896 [http://bugs.mysql.com/18896])

Event timings using the intervals `YEAR`, `QUARTER`, `MONTH`, and `YEAR_MONTH` are resolved in months; those using any other interval are resolved in seconds. There is no way to cause events scheduled to occur at the same second to execute in a given order. In addition — due to rounding, the nature of threaded applications, and the fact that a non-zero length of time is required to create events and to signal their execution — events may be delayed by as much as 1 or 2 seconds. However, the time shown in the `INFORMATION_SCHEMA.EVENTS` table's `LAST_EXECUTED` column or the `mysql.event` table's `last_executed` column is always accurate to within one second of the time the event was actually executed. (See also Bug#16522 [http://bugs.mysql.com/16522].)

Execution of event statements have no affect on the server's statement counts such as `Com_select` and `Com_insert` that are displayed by `SHOW STATUS`.

Prior to MySQL 5.1.12, you could not view another user's events in the `INFORMATION_SCHEMA.EVENTS` table. In other words, any query made against this table was treated as though it contained the condition `DEFINER = CURRENT_USER()` in the `WHERE` clause.

Events cannot be created with a start time that is in the past.

Events do not support times later than the end of the Unix Epoch; this is approximately the end of the year 2037). Prior to MySQL 5.1.8, handling in scheduled events of dates later than this was buggy; starting with MySQL 5.1.8, such dates are specifically disallowed by the Event Scheduler. (Bug#16396 [http://bugs.mysql.com/16396])

In MySQL 5.1.6, `INFORMATION_SCHEMA.EVENTS` shows `NULL` in the `SQL_MODE` column. Beginning with MySQL 5.1.7, the `SQL_MODE` displayed is that in effect when the event was created.

In MySQL 5.1.6, the only way to drop or alter an event created by a user who was not the definer of that event was by manipulation of the `mysql.event` system table by the MySQL `root` user or by another user with privileges on this table. Beginning with MySQL 5.1.7, `DROP USER` drops all events for which that user was the definer; also beginning with MySQL 5.1.7 `DROP SCHEMA` drops all events associated with the dropped schema.

As with stored routines, events are not migrated to the new schema by the `RENAME SCHEMA` (or `RENAME DATABASE`) statement. See Section 13.1.15, “`RENAME DATABASE Syntax`”.

Beginning with MySQL 5.1.8, event names are handled in case-insensitive fashion. For example, this means that you cannot have two events in the same database and with the same definer, and having the names `anEvent` and `AnEvent`. **Important:** If you have events created in MySQL 5.1.7 or earlier, which are assigned to the same database and have the same definer, and whose names differ only with respect to lettercase, then you must rename these events to respect case-sensitive handling before upgrading to MySQL 5.1.8 or later.

Chapter 21. Views

Views (including updatable views) are available in MySQL Server 5.1.

This chapter discusses the following topics:

- Creating or altering views with `CREATE VIEW` or `ALTER VIEW`
- Destroying views with `DROP VIEW`

Discussion of restrictions on use of views is given in [Section I.4, “Restrictions on Views”](#).

To use views if you have upgraded to MySQL 5.1 from an older release that did not support views, you should upgrade your grant tables so that they contain the view-related privileges. See [Section 5.6.2, “mysql_upgrade — Check Tables for MySQL Upgrade”](#).

Metadata about views can be obtained from the `INFORMATION_SCHEMA.VIEWS` table and by using the `SHOW CREATE VIEW` statement. See [Section 22.15, “The INFORMATION_SCHEMA VIEWS Table”](#), and [Section 13.5.4.10, “SHOW CREATE VIEW Syntax”](#).

21.1. ALTER VIEW Syntax

```
ALTER
[ALGORITHM = {UNDEFINED | MERGE | TEMPTABLE}]
[DEFINER = { user | CURRENT_USER }]
[SQL SECURITY { DEFINER | INVOKER }]
VIEW view_name [(column_list)]
AS select_statement
[WITH [CASCADED | LOCAL] CHECK OPTION]
```

This statement changes the definition of an existing view. The syntax is similar to that for `CREATE VIEW`. See [Section 21.2, “CREATE VIEW Syntax”](#). This statement requires the `CREATE VIEW` and `DROP` privileges for the view, and some privilege for each column referred to in the `SELECT` statement.

21.2. CREATE VIEW Syntax

```
CREATE
[OR REPLACE]
[ALGORITHM = {UNDEFINED | MERGE | TEMPTABLE}]
[DEFINER = { user | CURRENT_USER }]
[SQL SECURITY { DEFINER | INVOKER }]
VIEW view_name [(column_list)]
AS select_statement
[WITH [CASCADED | LOCAL] CHECK OPTION]
```

This statement creates a new view, or replaces an existing one if the `OR REPLACE` clause is given. The `select_statement` is a `SELECT` statement that provides the definition of the view. The statement can select from base tables or other views.

This statement requires the `CREATE VIEW` privilege for the view, and some privilege for each column selected by the `SELECT` statement. For columns used elsewhere in the `SELECT` statement you must have the `SELECT` privilege. If the `OR REPLACE` clause is present, you must also have the `DROP` privilege for the view.

A view belongs to a database. By default, a new view is created in the default database. To create the view explicitly in a given database, specify the name as `db_name.view_name` when you create it.

```
mysql> CREATE VIEW test.v AS SELECT * FROM t;
```

Base tables and views share the same namespace within a database, so a database cannot contain a base table and a view that have the same name.

Views must have unique column names with no duplicates, just like base tables. By default, the names of the columns retrieved by the `SELECT` statement are used for the view column names. To define explicit names for the view columns, the optional `column_list` clause can be given as a list of comma-separated identifiers. The number of names in `column_list` must be the same as the number of columns retrieved by the `SELECT` statement.

Columns retrieved by the `SELECT` statement can be simple references to table columns. They can also be expressions that use functions, constant values, operators, and so forth.

Unqualified table or view names in the `SELECT` statement are interpreted with respect to the default database. A view can refer to tables or views in other databases by qualifying the table or view name with the proper database name.

A view can be created from many kinds of `SELECT` statements. It can refer to base tables or other views. It can use joins, `UNION`, and subqueries. The `SELECT` need not even refer to any tables. The following example defines a view that selects two columns from another table, as well as an expression calculated from those columns:

```
mysql> CREATE TABLE t (qty INT, price INT);
mysql> INSERT INTO t VALUES(3, 50);
mysql> CREATE VIEW v AS SELECT qty, price, qty*price AS value FROM t;
mysql> SELECT * FROM v;
```

qty	price	value
3	50	150

A view definition is subject to the following restrictions:

- The `SELECT` statement cannot contain a subquery in the `FROM` clause.
- The `SELECT` statement cannot refer to system or user variables.
- The `SELECT` statement cannot refer to prepared statement parameters.
- Within a stored routine, the definition cannot refer to routine parameters or local variables.
- Any table or view referred to in the definition must exist. However, after a view has been created, it is possible to drop a table or view that the definition refers to. In this case, use of the view results in an error. To check a view definition for problems of this kind, use the `CHECK TABLE` statement.
- The definition cannot refer to a `TEMPORARY` table, and you cannot create a `TEMPORARY` view.
- The tables named in the view definition must already exist.
- You cannot associate a trigger with a view.

`ORDER BY` is allowed in a view definition, but it is ignored if you select from a view using a statement that has its own `ORDER BY`.

For other options or clauses in the definition, they are added to the options or clauses of the statement that references the view, but the effect is undefined. For example, if a view definition includes a `LIMIT` clause, and you select from the view using a statement that has its own `LIMIT` clause, it is undefined

which limit applies. This same principle applies to options such as [ALL](#), [DISTINCT](#), or [SQL_SMALL_RESULT](#) that follow the [SELECT](#) keyword, and to clauses such as [INTO](#), [FOR UPDATE](#), [LOCK IN SHARE MODE](#), and [PROCEDURE](#).

If you create a view and then change the query processing environment by changing system variables, that may affect the results that you get from the view:

```
mysql> CREATE VIEW v AS SELECT CHARSET(CHAR(65)), COLLATION(CHAR(65));
Query OK, 0 rows affected (0.00 sec)

mysql> SET NAMES 'latin1';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT * FROM v;
+-----+-----+
| CHARSET(CHAR(65)) | COLLATION(CHAR(65)) |
+-----+-----+
| latin1           | latin1_swedish_ci   |
+-----+-----+
1 row in set (0.00 sec)

mysql> SET NAMES 'utf8';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT * FROM v;
+-----+-----+
| CHARSET(CHAR(65)) | COLLATION(CHAR(65)) |
+-----+-----+
| utf8             | utf8_general_ci     |
+-----+-----+
1 row in set (0.00 sec)
```

The [DEFINER](#) and [SQL SECURITY](#) clauses specify the security context to be used when checking access privileges at view invocation time. They were added in MySQL 5.1.2.

[CURRENT_USER](#) also can be given as [CURRENT_USER\(\)](#).

Within a stored routine that is defined with the [SQL SECURITY DEFINER](#) characteristic, [CURRENT_USER](#) returns the routine creator. This also affects a view defined within such a routine, if the view definition contains a [DEFINER](#) value of [CURRENT_USER](#).

The default [DEFINER](#) value is the user who executes the [CREATE VIEW](#) statement. (This is the same as [DEFINER = CURRENT_USER](#).) If a *user* value is given, it should be a MySQL account in '*user_name*'@'*host_name*' format (the same format used in the [GRANT](#) statement). The *user_name* and *host_name* values both are required.

If you specify the [DEFINER](#) clause, you cannot set the value to any user but your own unless you have the [SUPER](#) privilege. These rules determine the legal [DEFINER](#) user values:

- If you do not have the [SUPER](#) privilege, the only legal *user* value is your own account, either specified literally or by using [CURRENT_USER](#). You cannot set the definer to some other account.
- If you have the [SUPER](#) privilege, you can specify any syntactically legal account name. If the account does not actually exist, a warning is generated.

The [SQL SECURITY](#) characteristic determines which MySQL account to use when checking access privileges for the view when the view is executed. The legal characteristic values are [DEFINER](#) and [INVOKER](#). These indicate that the view must be executable by the user who defined it or invoked it, respectively. The default [SQL SECURITY](#) value is [DEFINER](#).

As of MySQL 5.1.2 (when the [DEFINER](#) and [SQL SECURITY](#) clauses were implemented), view privileges are checked like this:

- At view definition time, the view creator must have the privileges needed to use the top-level objects accessed by the view. For example, if the view definition refers to a stored function, only the privileges needed to invoke the function can be checked. The privileges required when the function runs can be checked only as it executes: For different invocations of the function, different execution paths within the function might be taken.
- At view execution time, privileges for objects accessed by the view are checked against the privileges held by the view creator or invoker, depending on whether the `SQL SECURITY` characteristic is `DEFINER` or `INVOKER`, respectively.
- If view execution causes execution of a stored function, privilege checking for statements executed within the function depend on whether the function is defined with a `SQL SECURITY` characteristic of `DEFINER` or `INVOKER`. If the security characteristic is `DEFINER`, the function runs with the privileges of its creator. If the characteristic is `INVOKER`, the function runs with the privileges determined by the view's `SQL SECURITY` characteristic.

Prior to MySQL 5.1.2 (before the `DEFINER` and `SQL SECURITY` clauses were implemented), privileges required for objects used in a view are checked at view creation time.

Example: A view might depend on a stored function, and that function might invoke other stored routines. For example, the following view invokes a stored function `f()`:

```
CREATE VIEW v AS SELECT * FROM t WHERE t.id = f(t.name);
```

Suppose that `f()` contains a statement such as this:

```
IF name IS NULL then
  CALL p1();
ELSE
  CALL p2();
END IF;
```

The privileges required for executing statements within `f()` need to be checked when `f()` executes. This might mean that privileges are needed for `p1()` or `p2()`, depending on the execution path within `f()`. Those privileges need to be checked at runtime, and the user who must possess the privileges is determined by the `SQL SECURITY` values of the function `f()` and the view `v`.

The `DEFINER` and `SQL SECURITY` clauses for views are extensions to standard SQL. In standard SQL, views are handled using the rules for `SQL SECURITY INVOKER`.

If you invoke a view that was created before MySQL 5.0.13/5.1.2, it is treated as though it was created with a `SQL SECURITY DEFINER` clause and with a `DEFINER` value that is the same as your account. However, because the actual definer is unknown, MySQL issues a warning. To make the warning go away, it is sufficient to re-create the view so that the view definition includes a `DEFINER` clause.

The optional `ALGORITHM` clause is a MySQL extension to standard SQL. `ALGORITHM` takes three values: `MERGE`, `TEMPTABLE`, or `UNDEFINED`. The default algorithm is `UNDEFINED` if no `ALGORITHM` clause is present. The algorithm affects how MySQL processes the view.

For `MERGE`, the text of a statement that refers to the view and the view definition are merged such that parts of the view definition replace corresponding parts of the statement.

For `TEMPTABLE`, the results from the view are retrieved into a temporary table, which then is used to execute the statement.

For `UNDEFINED`, MySQL chooses which algorithm to use. It prefers `MERGE` over `TEMPTABLE` if possible, because `MERGE` is usually more efficient and because a view cannot be updatable if a temporary table is used.

A reason to choose `TEMPTABLE` explicitly is that locks can be released on underlying tables after the temporary table has been created and before it is used to finish processing the statement. This might result in quicker lock release than the `MERGE` algorithm so that other clients that use the view are not blocked as long.

A view algorithm can be `UNDEFINED` for three reasons:

- No `ALGORITHM` clause is present in the `CREATE VIEW` statement.
- The `CREATE VIEW` statement has an explicit `ALGORITHM = UNDEFINED` clause.
- `ALGORITHM = MERGE` is specified for a view that can be processed only with a temporary table. In this case, MySQL generates a warning and sets the algorithm to `UNDEFINED`.

As mentioned earlier, `MERGE` is handled by merging corresponding parts of a view definition into the statement that refers to the view. The following examples briefly illustrate how the `MERGE` algorithm works. The examples assume that there is a view `v_merge` that has this definition:

```
CREATE ALGORITHM = MERGE VIEW v_merge (vc1, vc2) AS
SELECT c1, c2 FROM t WHERE c3 > 100;
```

Example 1: Suppose that we issue this statement:

```
SELECT * FROM v_merge;
```

MySQL handles the statement as follows:

- `v_merge` becomes `t`
- `*` becomes `vc1, vc2`, which corresponds to `c1, c2`
- The view `WHERE` clause is added

The resulting statement to be executed becomes:

```
SELECT c1, c2 FROM t WHERE c3 > 100;
```

Example 2: Suppose that we issue this statement:

```
SELECT * FROM v_merge WHERE vc1 < 100;
```

This statement is handled similarly to the previous one, except that `vc1 < 100` becomes `c1 < 100` and the view `WHERE` clause is added to the statement `WHERE` clause using an `AND` connective (and parentheses are added to make sure the parts of the clause are executed with correct precedence). The resulting statement to be executed becomes:

```
SELECT c1, c2 FROM t WHERE (c3 > 100) AND (c1 < 100);
```

Effectively, the statement to be executed has a `WHERE` clause of this form:

```
WHERE (select WHERE) AND (view WHERE)
```

The `MERGE` algorithm requires a one-to-one relationship between the rows in the view and the rows in

the underlying table. If this relationship does not hold, a temporary table must be used instead. Lack of a one-to-one relationship occurs if the view contains any of a number of constructs:

- Aggregate functions (`SUM()`, `MIN()`, `MAX()`, `COUNT()`, and so forth)
- `DISTINCT`
- `GROUP BY`
- `HAVING`
- `UNION` or `UNION ALL`
- Refers only to literal values (in this case, there is no underlying table)

Some views are updatable. That is, you can use them in statements such as `UPDATE`, `DELETE`, or `INSERT` to update the contents of the underlying table. For a view to be updatable, there must be a one-to-one relationship between the rows in the view and the rows in the underlying table. There are also certain other constructs that make a view non-updatable. To be more specific, a view is not updatable if it contains any of the following:

- Aggregate functions (`SUM()`, `MIN()`, `MAX()`, `COUNT()`, and so forth)
- `DISTINCT`
- `GROUP BY`
- `HAVING`
- `UNION` or `UNION ALL`
- Subquery in the select list
- Join
- Non-updatable view in the `FROM` clause
- A subquery in the `WHERE` clause that refers to a table in the `FROM` clause
- Refers only to literal values (in this case, there is no underlying table to update)
- `ALGORITHM = TEMPTABLE` (use of a temporary table always makes a view non-updatable)

With respect to insertability (being updatable with `INSERT` statements), an updatable view is insertable if it also satisfies these additional requirements for the view columns:

- There must be no duplicate view column names.
- The view must contain all columns in the base table that do not have a default value.
- The view columns must be simple column references and not derived columns. A derived column is one that is not a simple column reference but is derived from an expression. These are examples of derived columns:

```
3.14159  
col1 + 3  
UPPER(col2)
```

```
col3 / col4
(subquery)
```

A view that has a mix of simple column references and derived columns is not insertable, but it can be updatable if you update only those columns that are not derived. Consider this view:

```
CREATE VIEW v AS SELECT col1, 1 AS col2 FROM t;
```

This view is not insertable because `col2` is derived from an expression. But it is updatable if the update does not try to update `col2`. This update is allowable:

```
UPDATE v SET col1 = 0;
```

This update is not allowable because it attempts to update a derived column:

```
UPDATE v SET col2 = 0;
```

It is sometimes possible for a multiple-table view to be updatable, assuming that it can be processed with the [MERGE](#) algorithm. For this to work, the view must use an inner join (not an outer join or a [UNION](#)). Also, only a single table in the view definition can be updated, so the [SET](#) clause must name only columns from one of the tables in the view. Views that use [UNION ALL](#) are disallowed even though they might be theoretically updatable, because the implementation uses temporary tables to process them.

For a multiple-table updatable view, [INSERT](#) can work if it inserts into a single table. [DELETE](#) is not supported.

The [WITH CHECK OPTION](#) clause can be given for an updatable view to prevent inserts or updates to rows except those for which the [WHERE](#) clause in the *select_statement* is true.

In a [WITH CHECK OPTION](#) clause for an updatable view, the [LOCAL](#) and [CASCADED](#) keywords determine the scope of check testing when the view is defined in terms of another view. The [LOCAL](#) keyword restricts the [CHECK OPTION](#) only to the view being defined. [CASCADED](#) causes the checks for underlying views to be evaluated as well. When neither keyword is given, the default is [CASCADED](#). Consider the definitions for the following table and set of views:

```
mysql> CREATE TABLE t1 (a INT);
mysql> CREATE VIEW v1 AS SELECT * FROM t1 WHERE a < 2
-> WITH CHECK OPTION;
mysql> CREATE VIEW v2 AS SELECT * FROM v1 WHERE a > 0
-> WITH LOCAL CHECK OPTION;
mysql> CREATE VIEW v3 AS SELECT * FROM v1 WHERE a > 0
-> WITH CASCADED CHECK OPTION;
```

Here the `v2` and `v3` views are defined in terms of another view, `v1`. `v2` has a [LOCAL](#) check option, so inserts are tested only against the `v2` check. `v3` has a [CASCADED](#) check option, so inserts are tested not only against its own check, but against those of underlying views. The following statements illustrate these differences:

```
mysql> INSERT INTO v2 VALUES (2);
Query OK, 1 row affected (0.00 sec)
mysql> INSERT INTO v3 VALUES (2);
ERROR 1369 (HY000): CHECK OPTION failed 'test.v3'
```

The updatability of views may be affected by the value of the [updatable_views_with_limit](#) system variable. See [Section 5.2.3, “System Variables”](#).

21.3. DROP VIEW Syntax

```
DROP VIEW [IF EXISTS]
  view_name [, view_name] ...
  [RESTRICT | CASCADE]
```

`DROP VIEW` removes one or more views. You must have the `DROP` privilege for each view. If any of the views named in the argument list do not exist, MySQL returns an error indicating by name which non-existing views it was unable to drop, but it also drops all of the views in the list that do exist.

The `IF EXISTS` clause prevents an error from occurring for views that don't exist. When this clause is given, a `NOTE` is generated for each non-existent view. See [Section 13.5.4.30](#), “`SHOW WARNINGS Syntax`”.

`RESTRICT` and `CASCADE`, if given, are parsed and ignored.

Chapter 22. The `INFORMATION_SCHEMA` Database

`INFORMATION_SCHEMA` provides access to database metadata.

Metadata is data about the data, such as the name of a database or table, the data type of a column, or access privileges. Other terms that sometimes are used for this information are *data dictionary* and *system catalog*.

`INFORMATION_SCHEMA` is the information database, the place that stores information about all the other databases that the MySQL server maintains. Inside `INFORMATION_SCHEMA` there are several read-only tables. They are actually views, not base tables, so there are no files associated with them.

In effect, we have a database named `INFORMATION_SCHEMA`, although the server does not create a database directory with that name. It is possible to select `INFORMATION_SCHEMA` as the default database with a `USE` statement, but it is possible only to read the contents of tables. You cannot insert into them, update them, or delete from them.

Here is an example of a statement that retrieves information from `INFORMATION_SCHEMA`:

```
mysql> SELECT table_name, table_type, engine
-> FROM information_schema.tables
-> WHERE table_schema = 'db5'
-> ORDER BY table_name DESC;
+-----+-----+-----+
| table_name | table_type | engine |
+-----+-----+-----+
| v56        | VIEW       | NULL   |
| v3         | VIEW       | NULL   |
| v2         | VIEW       | NULL   |
| v          | VIEW       | NULL   |
| tables     | BASE TABLE | MyISAM |
| t7         | BASE TABLE | MyISAM |
| t3         | BASE TABLE | MyISAM |
| t2         | BASE TABLE | MyISAM |
| t          | BASE TABLE | MyISAM |
| pk         | BASE TABLE | InnoDB |
| loop       | BASE TABLE | MyISAM |
| kurs       | BASE TABLE | MyISAM |
| k          | BASE TABLE | MyISAM |
| into       | BASE TABLE | MyISAM |
| goto       | BASE TABLE | MyISAM |
| fk2        | BASE TABLE | InnoDB |
| fk         | BASE TABLE | InnoDB |
+-----+-----+-----+
17 rows in set (0.01 sec)
```

Explanation: The statement requests a list of all the tables in database `db5`, in reverse alphabetical order, showing just three pieces of information: the name of the table, its type, and its storage engine.

Each MySQL user has the right to access these tables, but can see only the rows in the tables that correspond to objects for which the user has the proper access privileges. In some cases (for example, the `ROUTINE_DEFINITION` column in the `INFORMATION_SCHEMA.ROUTINES` table), users who have insufficient privileges will see `NULL`.

The `SELECT ... FROM INFORMATION_SCHEMA` statement is intended as a more consistent way to provide access to the information provided by the various `SHOW` statements that MySQL supports (`SHOW DATABASES`, `SHOW TABLES`, and so forth). Using `SELECT` has these advantages, compared to `SHOW`:

- It conforms to Codd's rules. That is, all access is done on tables.

- Nobody needs to learn a new statement syntax. Because they already know how `SELECT` works, they only need to learn the object names.
- The implementor need not worry about adding keywords.
- There are millions of possible output variations, instead of just one. This provides more flexibility for applications that have varying requirements about what metadata they need.
- Migration is easier because every other DBMS does it this way.

However, because `SHOW` is popular with MySQL employees and users, and because it might be confusing were it to disappear, the advantages of conventional syntax are not a sufficient reason to eliminate `SHOW`. In fact, along with the implementation of `INFORMATION_SCHEMA`, there are enhancements to `SHOW` as well. These are described in [Section 22.27, “Extensions to SHOW Statements”](#).

There is no difference between the privileges required for `SHOW` statements and those required to select information from `INFORMATION_SCHEMA`. In either case, you have to have some privilege on an object in order to see information about it.

The implementation for the `INFORMATION_SCHEMA` table structures in MySQL follows the ANSI/ISO SQL:2003 standard Part 11 *Schemata*. Our intent is approximate compliance with SQL:2003 core feature F021 *Basic information schema*.

Users of SQL Server 2000 (which also follows the standard) may notice a strong similarity. However, MySQL has omitted many columns that are not relevant for our implementation, and added columns that are MySQL-specific. One such column is the `ENGINE` column in the `INFORMATION_SCHEMA.TABLES` table.

Although other DBMSs use a variety of names, like `syscat` or `system`, the standard name is `INFORMATION_SCHEMA`.

The following sections describe each of the tables and columns that are in `INFORMATION_SCHEMA`. For each column, there are three pieces of information:

- “`INFORMATION_SCHEMA Name`” indicates the name for the column in the `INFORMATION_SCHEMA` table. This corresponds to the standard SQL name unless the “Remarks” field says “MySQL extension.”
- “`SHOW Name`” indicates the equivalent field name in the closest `SHOW` statement, if there is one.
- “Remarks” provides additional information where applicable. If this field is `NULL`, it means that the value of the column is always `NULL`. If this field says “MySQL extension,” the column is a MySQL extension to standard SQL.

To avoid using any name that is reserved in the standard or in DB2, SQL Server, or Oracle, we changed the names of some columns marked “MySQL extension”. (For example, we changed `COLLATION` to `TABLE_COLLATION` in the `TABLES` table.) See the list of reserved words near the end of this article: <http://www.dbazine.com/gulutzan5.shtml>.

The definition for character columns (for example, `TABLES.TABLE_NAME`) is generally `VARCHAR(N) CHARACTER SET utf8` where `N` is at least 64.

Each section indicates what `SHOW` statement is equivalent to a `SELECT` that retrieves information from `INFORMATION_SCHEMA`, if there is such a statement.

Note: At present, there are some missing columns and some columns out of order. We are working on

this and update the documentation as changes are made.

22.1. The INFORMATION_SCHEMA SCHEMATA Table

A schema is a database, so the SCHEMATA table provides information about databases.

INFORMATION_SCHEMA Name	SHOW Name	Remarks
CATALOG_NAME		NULL
SCHEMA_NAME		Database
DEFAULT_CHARACTER_SET_NAME		
DEFAULT_COLLATION_NAME		
SQL_PATH		NULL

The following statements are equivalent:

```
SELECT SCHEMA_NAME AS `Database`
FROM INFORMATION_SCHEMA.SCHEMATA
 [WHERE SCHEMA_NAME LIKE 'wild']

SHOW DATABASES
 [LIKE 'wild']
```

22.2. The INFORMATION_SCHEMA TABLES Table

The TABLES table provides information about tables in databases.

INFORMATION_SCHEMA Name	SHOW Name	Remarks
TABLE_CATALOG		NULL
TABLE_SCHEMA	Table_...	
TABLE_NAME	Table_...	
TABLE_TYPE		
ENGINE	Engine	MySQL extension
VERSION	Version	MySQL extension
ROW_FORMAT	Row_format	MySQL extension
TABLE_ROWS	Rows	MySQL extension
AVG_ROW_LENGTH	Avg_row_length	MySQL extension
DATA_LENGTH	Data_length	MySQL extension
MAX_DATA_LENGTH	Max_data_length	MySQL extension
INDEX_LENGTH	Index_length	MySQL extension
DATA_FREE	Data_free	MySQL extension
AUTO_INCREMENT	Auto_increment	MySQL extension
CREATE_TIME	Create_time	MySQL extension
UPDATE_TIME	Update_time	MySQL extension
CHECK_TIME	Check_time	MySQL extension
TABLE_COLLATION	Collation	MySQL extension
CHECKSUM	Checksum	MySQL extension
CREATE_OPTIONS	Create_options	MySQL extension

TABLE_COMMENT	Comment	MySQL extension
---------------	---------	-----------------

Notes:

- TABLE_SCHEMA and TABLE_NAME are a single field in a SHOW display, for example Table_in_db1.
- TABLE_TYPE should be BASE TABLE or VIEW. If table is temporary, then TABLE_TYPE = TEMPORARY. (There are no temporary views, so this is not ambiguous.)
- For partitioned tables, beginning with MySQL 5.1.9, the ENGINE column shows the name of the storage engine used by all partitions. (Previously, this column showed PARTITION for such tables.)
- The TABLE_ROWS column is NULL if the table is in the INFORMATION_SCHEMA database. For InnoDB tables, the row count is only a rough estimate used in SQL optimization.
- For tables using the NDBCLUSTER storage engine, beginning with MySQL 5.1.12, the DATA_LENGTH column reflects the true amount of storage for variable-width columns. (See Bug#18413 [http://bugs.mysql.com/18413].)

Note: Because MySQL Cluster allocates storage for variable-width columns in 10-page extents of 32 kilobytes each, space usage for such columns is reported in increments of 320 KB.

- We have nothing for the table's default character set. TABLE_COLLATION is close, because collation names begin with a character set name.
- Beginning with MySQL 5.1.9, the CREATE_OPTIONS column shows *partitioned* if the table is partitioned.

The following statements are equivalent:

```
SELECT table_name FROM INFORMATION_SCHEMA.TABLES
  [WHERE table_schema = 'db_name']
  [WHERE|AND table_name LIKE 'wild']

SHOW TABLES
  [FROM db_name]
  [LIKE 'wild']
```

22.3. The INFORMATION_SCHEMA COLUMNS Table

The COLUMNS table provides information about columns in tables.

INFORMATION_SCHEMA Name	SHOW Name	Remarks
TABLE_CATALOG		NULL
TABLE_SCHEMA		
TABLE_NAME		
COLUMN_NAME	Field	
ORDINAL_POSITION		see notes
COLUMN_DEFAULT	Default	
IS_NULLABLE	Null	
DATA_TYPE	Type	

CHARACTER_MAXIMUM_LENGTH	Type	
CHARACTER_OCTET_LENGTH		
NUMERIC_PRECISION	Type	
NUMERIC_SCALE	Type	
CHARACTER_SET_NAME		
COLLATION_NAME	Collation	
COLUMN_TYPE	Type	MySQL extension
COLUMN_KEY	Key	MySQL extension
EXTRA	Extra	MySQL extension
COLUMN_COMMENT	Comment	MySQL extension

Notes:

- In `SHOW`, the `Type` display includes values from several different `COLUMNS` columns.
- `ORDINAL_POSITION` is necessary because you might want to say `ORDER BY ORDINAL_POSITION`. Unlike `SHOW`, `SELECT` does not have automatic ordering.
- `CHARACTER_OCTET_LENGTH` should be the same as `CHARACTER_MAXIMUM_LENGTH`, except for multi-byte character sets.
- `CHARACTER_SET_NAME` can be derived from `Collation`. For example, if you say `SHOW FULL COLUMNS FROM t`, and you see in the `Collation` column a value of `latin1_swedish_ci`, the character set is what's before the first underscore: `latin1`.

The following statements are nearly equivalent:

```
SELECT COLUMN_NAME, DATA_TYPE, IS_NULLABLE, COLUMN_DEFAULT
FROM INFORMATION_SCHEMA.COLUMNS
WHERE table_name = 'tbl_name'
[AND table_schema = 'db_name']
[AND column_name LIKE 'wild']

SHOW COLUMNS
FROM tbl_name
[FROM db_name]
[LIKE 'wild']
```

22.4. The INFORMATION_SCHEMA STATISTICS Table

The `STATISTICS` table provides information about table indexes.

INFORMATION_SCHEMA Name	SHOW Name	Remarks
TABLE_CATALOG		NULL
TABLE_SCHEMA		= Database
TABLE_NAME	Table	
NON_UNIQUE	Non_unique	
INDEX_SCHEMA		= Database
INDEX_NAME	Key_name	
SEQ_IN_INDEX	Seq_in_index	

COLUMN_NAME	Column_name	
COLLATION	Collation	
CARDINALITY	Cardinality	
SUB_PART	Sub_part	MySQL extension
PACKED	Packed	MySQL extension
NULLABLE	Null	MySQL extension
INDEX_TYPE	Index_type	MySQL extension
COMMENT	Comment	MySQL extension

Notes:

- There is no standard table for indexes. The preceding list is similar to what SQL Server 2000 returns for `sp_statistics`, except that we replaced the name `QUALIFIER` with `CATALOG` and we replaced the name `OWNER` with `SCHEMA`.

Clearly, the preceding table and the output from `SHOW INDEX` are derived from the same parent. So the correlation is already close.

The following statements are equivalent:

```
SELECT * FROM INFORMATION_SCHEMA.STATISTICS
  WHERE table_name = 'tbl_name'
  [AND table_schema = 'db_name']

SHOW INDEX
  FROM tbl_name
  [FROM db_name]
```

22.5. The INFORMATION_SCHEMA USER_PRIVILEGES Table

The `USER_PRIVILEGES` table provides information about global privileges. This information comes from the `mysql.user` grant table.

INFORMATION_SCHEMA Name	SHOW Name	Remarks
GRANTEE		<code>host_na</code> <code>'user_name'@'me'</code> value, MySQL extension
TABLE_CATALOG		<code>NULL</code> , MySQL extension
PRIVILEGE_TYPE		MySQL extension
IS_GRANTABLE		MySQL extension

Notes:

- This is a non-standard table. It takes its values from the `mysql.user` table.

22.6. The INFORMATION_SCHEMA SCHEMA_PRIVILEGES Table

The `SCHEMA_PRIVILEGES` table provides information about schema (database) privileges. This information comes from the `mysql.db` grant table.

INFORMATION_SCHEMA Name	SHOW Name	Remarks
GRANTEE		<i>host_na</i> <i>'user_name'@'me'</i> value, MySQL extension
TABLE_CATALOG		NULL, MySQL extension
TABLE_SCHEMA		MySQL extension
PRIVILEGE_TYPE		MySQL extension
IS_GRANTABLE		MySQL extension

Notes:

- This is a non-standard table. It takes its values from the `mysql.db` table.

22.7. The INFORMATION_SCHEMA TABLE_PRIVILEGES Table

The `TABLE_PRIVILEGES` table provides information about table privileges. This information comes from the `mysql.tables_priv` grant table.

INFORMATION_SCHEMA Name	SHOW Name	Remarks
GRANTEE		<i>host_na</i> <i>'user_name'@'me'</i> value
TABLE_CATALOG		NULL
TABLE_SCHEMA		
TABLE_NAME		
PRIVILEGE_TYPE		
IS_GRANTABLE		

Notes:

- `PRIVILEGE_TYPE` can contain one (and only one) of these values: `SELECT`, `INSERT`, `UPDATE`, `REFERENCES`, `ALTER`, `INDEX`, `DROP`, `CREATE VIEW`.

The following statements are *not* equivalent:

```
SELECT ... FROM INFORMATION_SCHEMA.TABLE_PRIVILEGES
SHOW GRANTS ...
```

22.8. The INFORMATION_SCHEMA COLUMN_PRIVILEGES Table

The `COLUMN_PRIVILEGES` table provides information about column privileges. This information comes from the `mysql.columns_priv` grant table.

INFORMATION_SCHEMA Name	SHOW Name	Remarks
GRANTEE		<code>host_name</code> ' <code>user_name</code> '@' <code>me</code> ' value
TABLE_CATALOG		NULL
TABLE_SCHEMA		
TABLE_NAME		
COLUMN_NAME		
PRIVILEGE_TYPE		
IS_GRANTABLE		

Notes:

- In the output from `SHOW FULL COLUMNS`, the privileges are all in one field and in lowercase, for example, `select,insert,update,references`. In `COLUMN_PRIVILEGES`, there is one privilege per row, in uppercase.
- `PRIVILEGE_TYPE` can contain one (and only one) of these values: `SELECT`, `INSERT`, `UPDATE`, `REFERENCES`.
- If the user has `GRANT OPTION` privilege, `IS_GRANTABLE` should be `YES`. Otherwise, `IS_GRANTABLE` should be `NO`. The output does not list `GRANT OPTION` as a separate privilege.

The following statements are *not* equivalent:

```
SELECT ... FROM INFORMATION_SCHEMA.COLUMN_PRIVILEGES
SHOW GRANTS ...
```

22.9. The INFORMATION_SCHEMA CHARACTER_SETS Table

The `CHARACTER_SETS` table provides information about available character sets.

INFORMATION_SCHEMA Name	SHOW Name	Remarks
CHARACTER_SET_NAME	Charset	
DEFAULT_COLLATE_NAME	Default collation	
DESCRIPTION	Description	MySQL extension
MAXLEN	Maxlen	MySQL extension

The following statements are equivalent:

```
SELECT * FROM INFORMATION_SCHEMA.CHARACTER_SETS
```

```
[WHERE name LIKE 'wild']
SHOW CHARACTER SET
[LIKE 'wild']
```

22.10. The INFORMATION_SCHEMA COLLATIONS Table

The `COLLATIONS` table provides information about collations for each character set.

INFORMATION_SCHEMA Name	SHOW Name	Remarks
COLLATION_NAME	Collation	
CHARACTER_SET_NAME	Charset	MySQL extension
ID	Id	MySQL extension
IS_DEFAULT	Default	MySQL extension
IS_COMPILED	Compiled	MySQL extension
SORTLEN	Sortlen	MySQL extension

The following statements are equivalent:

```
SELECT COLLATION_NAME FROM INFORMATION_SCHEMA.COLLATIONS
[WHERE collation_name LIKE 'wild']

SHOW COLLATION
[LIKE 'wild']
```

22.11. The INFORMATION_SCHEMA COLLATION_CHARACTER_SET_APPLICABILITY Table

The `COLLATION_CHARACTER_SET_APPLICABILITY` table indicates what character set is applicable for what collation. The columns are equivalent to the first two display fields that we get from `SHOW COLLATION`.

INFORMATION_SCHEMA Name	SHOW Name	Remarks
COLLATION_NAME	Collation	
CHARACTER_SET_NAME	Charset	

22.12. The INFORMATION_SCHEMA TABLE_CONSTRAINTS Table

The `TABLE_CONSTRAINTS` table describes which tables have constraints.

INFORMATION_SCHEMA Name	SHOW Name	Remarks
CONSTRAINT_CATALOG		NULL
CONSTRAINT_SCHEMA		
CONSTRAINT_NAME		
TABLE_SCHEMA		
TABLE_NAME		

CONSTRAINT_TYPE		
-----------------	--	--

Notes:

- The `CONSTRAINT_TYPE` value can be `UNIQUE`, `PRIMARY KEY`, or `FOREIGN KEY`.
- The `UNIQUE` and `PRIMARY KEY` information is about the same as what you get from the `Key_name` field in the output from `SHOW INDEX` when the `Non_unique` field is 0.
- The `CONSTRAINT_TYPE` column can contain one of these values: `UNIQUE`, `PRIMARY KEY`, `FOREIGN KEY`, `CHECK`. This is a `CHAR` (not `ENUM`) column. The `CHECK` value is not available until we support `CHECK`.

22.13. The INFORMATION_SCHEMA KEY_COLUMN_USAGE Table

The `KEY_COLUMN_USAGE` table describes which key columns have constraints.

INFORMATION_SCHEMA Name	SHOW Name	Remarks
<code>CONSTRAINT_CATALOG</code>		<code>NULL</code>
<code>CONSTRAINT_SCHEMA</code>		
<code>CONSTRAINT_NAME</code>		
<code>TABLE_CATALOG</code>		
<code>TABLE_SCHEMA</code>		
<code>TABLE_NAME</code>		
<code>COLUMN_NAME</code>		
<code>ORDINAL_POSITION</code>		
<code>POSITION_IN_UNIQUE_CONSTRAINT</code>		
<code>REFERENCED_TABLE_SCHEMA</code>		
<code>REFERENCED_TABLE_NAME</code>		
<code>REFERENCED_COLUMN_NAME</code>		

Notes:

- If the constraint is a foreign key, then this is the column of the foreign key, not the column that the foreign key references.
- The value of `ORDINAL_POSITION` is the column's position within the constraint, not the column's position within the table. Column positions are numbered beginning with 1.
- The value of `POSITION_IN_UNIQUE_CONSTRAINT` is `NULL` for unique and primary-key constraints. For foreign-key constraints, it is the ordinal position in key of the table that is being referenced.

For example, suppose that there are two tables name `t1` and `t3` that have the following definitions:

```

CREATE TABLE t1
(
  s1 INT,
  s2 INT,
  s3 INT,
  PRIMARY KEY(s3)
) ENGINE=InnoDB;

CREATE TABLE t3
(
  s1 INT,
  s2 INT,
  s3 INT,
  KEY(s1),
  CONSTRAINT CO FOREIGN KEY (s2) REFERENCES t1(s3)
) ENGINE=InnoDB;

```

For those two tables, the `KEY_COLUMN_USAGE` table has two rows:

- One row with `CONSTRAINT_NAME = 'PRIMARY'`, `TABLE_NAME = 't1'`, `COLUMN_NAME = 's3'`, `ORDINAL_POSITION = 1`, `POSITION_IN_UNIQUE_CONSTRAINT = NULL`.
- One row with `CONSTRAINT_NAME = 'CO'`, `TABLE_NAME = 't3'`, `COLUMN_NAME = 's2'`, `ORDINAL_POSITION = 1`, `POSITION_IN_UNIQUE_CONSTRAINT = 1`.

22.14. The INFORMATION_SCHEMA ROUTINES Table

The `ROUTINES` table provides information about stored routines (both procedures and functions). The `ROUTINES` table does not include user-defined functions (UDFs) at this time.

The column named “`mysql.proc name`” indicates the `mysql.proc` table column that corresponds to the `INFORMATION_SCHEMA.ROUTINES` table column, if any.

INFORMATION_SCHEMA Name	mysql.proc Name	Remarks
<code>SPECIFIC_NAME</code>	<code>specific_name</code>	
<code>ROUTINE_CATALOG</code>		NULL
<code>ROUTINE_SCHEMA</code>	<code>db</code>	
<code>ROUTINE_NAME</code>	<code>name</code>	
<code>ROUTINE_TYPE</code>	<code>type</code>	{PROCEDURE FUNCTION}
<code>DTD_IDENTIFIER</code>		(data type descriptor)
<code>ROUTINE_BODY</code>		SQL
<code>ROUTINE_DEFINITION</code>	<code>body</code>	
<code>EXTERNAL_NAME</code>		NULL
<code>EXTERNAL_LANGUAGE</code>	<code>language</code>	NULL
<code>PARAMETER_STYLE</code>		SQL
<code>IS_DETERMINISTIC</code>	<code>is_deterministic</code>	
<code>SQL_DATA_ACCESS</code>	<code>sql_data_access</code>	
<code>SQL_PATH</code>		NULL
<code>SECURITY_TYPE</code>	<code>security_type</code>	
<code>CREATED</code>	<code>created</code>	
<code>LAST_ALTERED</code>	<code>modified</code>	
<code>SQL_MODE</code>	<code>sql_mode</code>	MySQL extension

ROUTINE_COMMENT	comment	MySQL extension
DEFINER	definer	MySQL extension

Notes:

- MySQL calculates `EXTERNAL_LANGUAGE` thus:
 - If `mysql.proc.language = 'SQL'`, `EXTERNAL_LANGUAGE` is `NULL`
 - Otherwise, `EXTERNAL_LANGUAGE` is what is in `mysql.proc.language`. However, we do not have external languages yet, so it is always `NULL`.

22.15. The INFORMATION_SCHEMA VIEWS Table

The `VIEWS` table provides information about views in databases. You must have the `SHOW VIEW` privilege to access this table.

INFORMATION_SCHEMA Name	SHOW Name	Remarks
TABLE_CATALOG		NULL
TABLE_SCHEMA		
TABLE_NAME		
VIEW_DEFINITION		
CHECK_OPTION		
IS_UPDATABLE		
DEFINER		
SECURITY_TYPE		

Notes:

- The `VIEW_DEFINITION` column has most of what you see in the `Create Table` field that `SHOW CREATE VIEW` produces. Skip the words before `SELECT` and skip the words `WITH CHECK OPTION`. Suppose that the original statement was:

```
CREATE VIEW v AS
  SELECT s2,s1 FROM t
  WHERE s1 > 5
  ORDER BY s1
  WITH CHECK OPTION;
```

Then the view definition looks like this:

```
SELECT s2,s1 FROM t WHERE s1 > 5 ORDER BY s1
```

- The `CHECK_OPTION` column always has a value of `NONE`.
- The `IS_UPDATABLE` column is `YES` if the view is updatable, `NO` if the view is not updatable.
- The `DEFINER` column indicates who defined the view. `SECURITY_TYPE` has a value of `DEFINER` or `INVOKER`.

22.16. The INFORMATION_SCHEMA TRIGGERS Table

The `TRIGGERS` table provides information about triggers. You must have the `SUPER` privilege to access this table.

INFORMATION_SCHEMA Name	SHOW Name	Remarks
TRIGGER_CATALOG		NULL
TRIGGER_SCHEMA		
TRIGGER_NAME	Trigger	
EVENT_MANIPULATION	Event	
EVENT_OBJECT_CATALOG		NULL
EVENT_OBJECT_SCHEMA		
EVENT_OBJECT_TABLE	Table	
ACTION_ORDER		0
ACTION_CONDITION		NULL
ACTION_STATEMENT	Statement	
ACTION_ORIENTATION		ROW
ACTION_TIMING	Timing	
ACTION_REFERENCE_OLD_TABLE		NULL
ACTION_REFERENCE_NEW_TABLE		NULL
ACTION_REFERENCE_OLD_ROW		OLD
ACTION_REFERENCE_NEW_ROW		NEW
CREATED		NULL (0)
SQL_MODE		MySQL extension
DEFINER		MySQL extension

Notes:

- The `TRIGGER_SCHEMA` and `TRIGGER_NAME` columns contain the name of the database in which the trigger occurs and the trigger name, respectively.
- The `EVENT_MANIPULATION` column contains one of the values 'INSERT', 'DELETE', or 'UPDATE'.
- As noted in [Chapter 19, Triggers](#), every trigger is associated with exactly one table. The `EVENT_OBJECT_SCHEMA` and `EVENT_OBJECT_TABLE` columns contain the database in which this table occurs, and the table's name.
- The `ACTION_ORDER` statement contains the ordinal position of the trigger's action within the list of all similar triggers on the same table. Currently, this value is always 0, because it is not possible to have more than one trigger with the same `EVENT_MANIPULATION` and `ACTION_TIMING` on the same table.
- The `ACTION_STATEMENT` column contains the statement to be executed when the trigger is invoked. This is the same as the text displayed in the `Statement` column of the output from `SHOW TRIGGERS`. Note that this text uses UTF-8 encoding.
- The `ACTION_ORIENTATION` column always contains the value 'ROW'.

- The `ACTION_TIMING` column contains one of the two values 'BEFORE' or 'AFTER'.
- The columns `ACTION_REFERENCE_OLD_ROW` and `ACTION_REFERENCE_NEW_ROW` contain the old and new column identifiers, respectively. This means that `ACTION_REFERENCE_OLD_ROW` always contains the value 'OLD' and `ACTION_REFERENCE_NEW_ROW` always contains the value 'NEW'.
- The `SQL_MODE` column shows the server SQL mode that was in effect at the time when the trigger was created (and thus which remains in effect for this trigger whenever it is invoked, *regardless of the current server SQL mode*). The possible range of values for this column is the same as that of the `sql_mode` system variable. See [Section 5.2.6, “SQL Modes”](#).
- The `DEFINER` column was added in MySQL 5.1.2. `DEFINER` indicates who defined the trigger.
- The following columns currently always contain NULL: `TRIGGER_CATALOG`, `EVENT_OBJECT_CATALOG`, `ACTION_CONDITION`, `ACTION_REFERENCE_OLD_TABLE`, `ACTION_REFERENCE_NEW_TABLE`, and `CREATED`.

Example, using the `ins_sum` trigger defined in [Section 19.3, “Using Triggers”](#):

```
mysql> SELECT * FROM INFORMATION_SCHEMA.TRIGGERS\G
***** 1. row *****
      TRIGGER_CATALOG: NULL
      TRIGGER_SCHEMA: test
      TRIGGER_NAME: ins_sum
      EVENT_MANIPULATION: INSERT
      EVENT_OBJECT_CATALOG: NULL
      EVENT_OBJECT_SCHEMA: test
      EVENT_OBJECT_TABLE: account
      ACTION_ORDER: 0
      ACTION_CONDITION: NULL
      ACTION_STATEMENT: SET @sum = @sum + NEW.amount
      ACTION_ORIENTATION: ROW
      ACTION_TIMING: BEFORE
      ACTION_REFERENCE_OLD_TABLE: NULL
      ACTION_REFERENCE_NEW_TABLE: NULL
      ACTION_REFERENCE_OLD_ROW: OLD
      ACTION_REFERENCE_NEW_ROW: NEW
      CREATED: NULL
      SQL_MODE:
      DEFINER: me@localhost
```

See also [Section 13.5.4.28, “SHOW TRIGGERS Syntax”](#).

22.17. The INFORMATION_SCHEMA PLUGINS Table

The `PLUGINS` table provides information about server plugins.

INFORMATION_SCHEMA Name	SHOW Name	Remarks
<code>PLUGIN_NAME</code>	Name	MySQL extension
<code>PLUGIN_VERSION</code>		MySQL extension
<code>PLUGIN_STATUS</code>	Status	MySQL extension
<code>PLUGIN_TYPE</code>	Type	MySQL extension
<code>PLUGIN_TYPE_VERSION</code>		MySQL extension
<code>PLUGIN_LIBRARY</code>	Library	MySQL extension
<code>PLUGIN_LIBRARY_VERSION</code>		MySQL extension
<code>PLUGIN_AUTHOR</code>		MySQL extension
<code>PLUGIN_DESCRIPTION</code>		MySQL extension

Notes:

- The `PLUGINS` table is a non-standard table. It was added in MySQL 5.1.5.

See also [Section 13.5.4.20](#), “`SHOW PLUGINS Syntax`”.

22.18. The INFORMATION_SCHEMA ENGINES Table

The `PLUGINS` table provides information about storage engines.

INFORMATION_SCHEMA Name	SHOW Name	Remarks
ENGINE	Engine	MySQL extension
SUPPORT	Support	MySQL extension
COMMENT	Comment	MySQL extension
TRANSACTIONS	Transactions	MySQL extension
XA	XA	MySQL extension
SAVEPOINTS	Savepoints	MySQL extension

Notes:

- The `ENGINES` table is a non-standard table. It was added in MySQL 5.1.5.

See also [Section 13.5.4.13](#), “`SHOW ENGINES Syntax`”.

22.19. The INFORMATION_SCHEMA PARTITIONS Table

The `PARTITIONS` table provides information about table partitions. See [Chapter 16, Partitioning](#), for more information about partitioning tables.

INFORMATION_SCHEMA Name	SHOW Name	Remarks
TABLE_CATALOG		MySQL extension
TABLE_SCHEMA		MySQL extension
TABLE_NAME		MySQL extension
PARTITION_NAME		MySQL extension
SUBPARTITION_NAME		MySQL extension
PARTITION_ORDINAL_POSITION		MySQL extension
SUBPARTITION_ORDINAL_POSITION		MySQL extension
PARTITION_METHOD		MySQL extension
SUBPARTITION_METHOD		MySQL extension
PARTITION_EXPRESSION		MySQL extension
SUBPARTITION_EXPRESSION		MySQL extension
PARTITION_DESCRIPTION		MySQL extension
TABLE_ROWS		MySQL extension

AVG_ROW_LENGTH		MySQL extension
DATA_LENGTH		MySQL extension
MAX_DATA_LENGTH		MySQL extension
INDEX_LENGTH		MySQL extension
DATA_FREE		MySQL extension
CREATE_TIME		MySQL extension
UPDATE_TIME		MySQL extension
CHECK_TIME		MySQL extension
CHECKSUM		MySQL extension
PARTITION_COMMENT		MySQL extension
NODEGROUP		MySQL extension
TABLESPACE_NAME		MySQL extension

Notes:

- The `PARTITIONS` table is a non-standard table. It was added in MySQL 5.1.6.
Each record in this table corresponds to an individual partition or subpartition of a partitioned table.
- `TABLE_CATALOG`: This column is always `NULL`.
- `TABLE_SCHEMA`: This column contains the name of the database to which the table belongs.
- `TABLE_NAME`: This column contains the name of the table containing the partition.
- `PARTITION_NAME`: The name of the partition.
- `SUBPARTITION_NAME`: If the `PARTITIONS` table record represents a subpartition, then this column contains the name of subpartition; otherwise it is `NULL`.
- `PARTITION_ORDINAL_POSITION`: All partitions are indexed in the same order as they are defined, with `1` being the number assigned to the first partition. The indexing can change as partitions are added, dropped, and reorganized; the number shown in this column reflects the current order, taking into account any indexing changes.
- `SUBPARTITION_ORDINAL_POSITION`: Subpartitions within a given partition are also indexed and reindexed in the same manner as partitions are indexed within a table.
- `PARTITION_METHOD`: One of the values `RANGE`, `LIST`, `HASH`, `LINEAR HASH`, `KEY`, or `LINEAR KEY`; that is, one of the available partitioning types as discussed in [Section 16.2, “Partition Types”](#).
- `SUBPARTITION_METHOD`: One of the values `HASH`, `LINEAR HASH`, `KEY`, or `LINEAR KEY`; that is, one of the available subpartitioning types as discussed in [Section 16.2.5, “Subpartitioning”](#).
- `PARTITION_EXPRESSION`: This is the expression for the partitioning function used in the `CREATE TABLE` or `ALTER TABLE` statement that created the table's current partitioning scheme.

For example, consider a partitioned table created in the `test` database using this statement:

```
CREATE TABLE tp (
  c1 INT,
  c2 INT,
```

```

    c3 VARCHAR(25)
)
PARTITION BY HASH(c1 + c2)
PARTITIONS 4;

```

The `PARTITION_EXPRESSION` column in a `PARTITIONS` table record for a partition from this table displays `c1 + c2`, as shown here:

```

mysql> SELECT DISTINCT PARTITION_EXPRESSION
> FROM INFORMATION_SCHEMA.PARTITIONS
> WHERE TABLE_NAME='tp' AND TABLE_SCHEMA='test';
+-----+
| PARTITION_EXPRESSION |
+-----+
| c1 + c2              |
+-----+
1 row in set (0.09 sec)

```

- `SUBPARTITION_EXPRESSION`: This works in the same fashion for the subpartitioning expression that defines the subpartitioning for a table as `PARTITION_EXPRESSION` does for the partitioning expression used to define a table's partitioning.

If the table has no subpartitions, then this column is `NULL`.

- `PARTITION_DESCRIPTION`: This column is used for `RANGE` and `LIST` partitions. For a `RANGE` partition, it contains the value set in the partition's `VALUES LESS THAN` clause, which can be either an integer or `MAXVALUE`. For a `LIST` partition, this column contains the values defined in the partition's `VALUES IN` clause, which is a comma-separated list of integer values.

For partitions whose `PARTITION_METHOD` is other than `RANGE` or `LIST`, this column is always `NULL`.

- `TABLE_ROWS`: The number of table rows in the partition.
- `AVG_ROW_LENGTH`: The average length of the rows stored in this partition or subpartition, in bytes.

This is the same as `DATA_LENGTH` divided by `TABLE_ROWS`.

- `DATA_LENGTH`: The total length of all rows stored in this partition or subpartition, in bytes — that is, the total number of bytes stored in the partition or subpartition.
- `MAX_DATA_LENGTH`: The maximum number of bytes that can be stored in this partition or subpartition.
- `INDEX_LENGTH`: The length of the index file for this partition or subpartition, in bytes.
- `DATA_FREE`: The number of bytes allocated to the partition or subpartition but not used.
- `CREATE_TIME`: The time of the partition's or subpartition's creation.
- `UPDATE_TIME`: The time that the partition or subpartition was last modified.
- `CHECK_TIME`: The last time that the table to which this partition or subpartition belongs was checked.

Note: Some storage engines do not update this time; for tables using these storage engines, this value is always `NULL`.

- `CHECKSUM`: The checksum value, if any; otherwise, this column is `NULL`.

- **PARTITION_COMMENT**: This column contains the text of any comment made for the partition.
The default value for this column is an empty string.
- **NODEGROUP**: This is the nodegroup to which the partition belongs. This is relevant only to MySQL Cluster tables; otherwise the value of this column is always 0.
- **TABLESPACE_NAME**: This column contains the name of tablespace to which the partition belongs. In MySQL 5.1, the value of this column is always **DEFAULT**.
- **Important**: If any partitioned tables created in a MySQL version prior to MySQL 5.1.6 are present following an upgrade to MySQL 5.1.6 or later, it is not possible to **SELECT** from, **SHOW**, or **DESCRIBE** the **PARTITIONS** table. See [Section D.1.7, “Changes in release 5.1.6 \(01 February 2006\)”](#) before upgrading from MySQL 5.1.5 or earlier to MySQL 5.1.6 or later.
- A non-partitioned table has one record in **INFORMATION_SCHEMA.PARTITIONS**; however, the values of the **PARTITION_NAME**, **SUBPARTITION_NAME**, **PARTITION_ORDINAL_POSITION**, **SUBPARTITION_ORDINAL_POSITION**, **PARTITION_METHOD**, **SUBPARTITION_METHOD**, **PARTITION_EXPRESSION**, **SUBPARTITION_EXPRESSION**, and **PARTITION_DESCRIPTION** columns are all **NULL**. (The **PARTITION_COMMENT** column in this case is blank.)

In MySQL 5.1, there is also only one record in the **PARTITIONS** table for a table using the **NDB-Cluster** storage engine. The same columns are also **NULL** (or empty) as for a non-partitioned table.

22.20. The INFORMATION_SCHEMA EVENTS Table

The **EVENTS** table provides information about scheduled events, which are discussed in [Chapter 20, Event Scheduler](#).

INFORMATION_SCHEMA Name	SHOW Name	Remarks
EVENT_CATALOG		NULL, MySQL extension
EVENT_SCHEMA	Db	MySQL extension
EVENT_NAME	Name	MySQL extension
DEFINER	Definer	MySQL extension
EVENT_BODY		MySQL extension
EVENT_DEFINITION		MySQL extension
EVENT_TYPE	Type	MySQL extension
EXECUTE_AT	Execute at	MySQL extension
INTERVAL_VALUE	Interval value	MySQL extension
INTERVAL_FIELD	Interval field	MySQL extension
SQL_MODE		MySQL extension
STARTS	Starts	MySQL extension
ENDS	Ends	MySQL extension
STATUS	Status	MySQL extension
ON_COMPLETION		MySQL extension
CREATED		MySQL extension
LAST_ALTERED		MySQL extension
LAST_EXECUTED		MySQL extension

EVENT_COMMENT		MySQL extension
---------------	--	-----------------

Notes:

- The `EVENTS` table is a non-standard table. It was added in MySQL 5.1.6.
- `EVENT_CATALOG`: The value of this column is always `NULL`.
- `EVENT_SCHEMA`: The name of the schema (database) to which this event belongs.
- `EVENT_NAME`: The name of the event.
- `DEFINER`: The user who created the event. Always displayed in '`user_name`'@'`host_name`' format.
- `EVENT_BODY`: The language used for the statements in the event's `DO` clause; in MySQL 5.1, this is always `SQL`.

This column was added in MySQL 5.1.12. It is not to be confused with the column of the same name (now named `EVENT_DEFINITION`) that existed in earlier MySQL versions.

- `EVENT_DEFINITION`: The text of the SQL statement making up the event's `DO` clause; in other words, the statement executed by this event.
- Note:** Prior to MySQL 5.1.12, this column was named `EVENT_BODY`.
- `EVENT_TYPE`: One of the two values `ONE TIME` or `RECURRING`.
 - `EXECUTE_AT`: For a one-time event, this is the `DATETIME` value specified in the `AT` clause of the `CREATE EVENT` statement used to create the event, or of the last `ALTER EVENT` statement that modified the event. The value shown in this column reflects the addition or subtraction of any `INTERVAL` value included in the event's `AT` clause. For example, if an event is created using `ON SCHEDULE AT CURRENT_TIMESTAMP + '1:6' DAY_HOUR`, and the event was created at 2006-02-09 14:05:30, the value shown in this column would be '`2006-02-10 20:05:30`'.
- If the event's timing is determined by an `EVERY` clause instead of an `AT` clause (that is, if the event is recurring), the value of this column is `NULL`.
- `INTERVAL_VALUE`: For recurring events, this column contains the numeric portion of the event's `EVERY` clause.
- For a one-time event (that is, an event whose timing is determined by an `AT` clause), this column's value is `NULL`.
- `INTERVAL_FIELD`: For recurring events, this column contains the units portion of the `EVERY` clause governing the timing of the event, prefixed with '`INTERVAL_`'. Thus, this column contains a value such as '`INTERVAL_YEAR`', '`INTERVAL_QUARTER`', '`INTERVAL_DAY`', and so on.
- For a one-time event (that is, an event whose timing is determined by an `AT` clause), this column's value is `NULL`.
- `SQL_MODE`: The SQL mode in effect at the time the event was created or altered.
 - `STARTS`: For a recurring event whose definition includes a `STARTS` clause, this column contains the corresponding `DATETIME` value. As with the `EXECUTE_AT` column, this value resolves any expressions used.

If there is no `STARTS` clause affecting the timing of the event, this column is empty. (Prior to MySQL 5.1.8, it contained `NULL` in such cases.)

- `ENDS`: For a recurring event whose definition includes a `ENDS` clause, this column contains the corresponding `DATETIME` value. As with the `EXECUTE_AT` column (see previous example), this value resolves any expressions used.

If there is no `ENDS` clause affecting the timing of the event, this column contains `NULL`.

- `STATUS`: One of the two values `ENABLED` or `DISABLED`.
- `ON_COMPLETION`: One of the two values `PRESERVE` or `NOT PRESERVE`.
- `CREATED`: The date and time when the event was created. This is a `DATETIME` value.
- `LAST_ALTERED`: The date and time when the event was last modified. This is a `DATETIME` value. If the event has not been modified since its creation, this column holds the same value as the `CREATED` column.
- `LAST_EXECUTED`: The date and time when the event last executed. A `DATETIME` value. If the event has never executed, this column's value is `NULL`.
- `EVENT_COMMENT`: The text of a comment, if the event has one. If there is no comment, the value of this column is an empty string.

Example: Suppose the user `jon@ghidora` creates an event named `e_daily`, and then modifies it a few minutes later using an `ALTER EVENT` statement, as shown here:

```
DELIMITER |
CREATE EVENT e_daily
ON SCHEDULE EVERY 1 DAY
STARTS CURRENT_TIMESTAMP + INTERVAL 6 HOUR
DISABLE
COMMENT 'Saves total number of sessions and
        clears the table once per day.'
DO
BEGIN
INSERT INTO site_activity.totals (when, total)
SELECT CURRENT_TIMESTAMP, COUNT(*)
FROM site_activity.sessions;
DELETE FROM site_activity.sessions;
END |
DELIMITER ;
ALTER EVENT e_daily
ENABLED;
```

(Note that comments can span multiple lines.)

This user can then run the following `SELECT` statement, and obtain the output shown:

```
mysql> SELECT * FROM INFORMATION_SCHEMA.EVENTS
> WHERE EVENT_NAME = 'e_daily'
> AND EVENT_SCHEMA = 'myschema'\G
***** 1. row *****
EVENT_CATALOG: NULL
EVENT_SCHEMA: myschema
EVENT_NAME: e_daily
DEFINER: jon@ghidora
EVENT_BODY: BEGIN
                INSERT INTO site_activity.totals (when, total)
                SELECT CURRENT_TIMESTAMP, COUNT(*)
```

```

        FROM site_activity.sessions;
        DELETE FROM site_activity.sessions;
    END
    EVENT_TYPE: RECURRING
    EXECUTE_AT: NULL
    INTERVAL_VALUE: 1
    INTERVAL_FIELD: INTERVAL_DAY
    SQL_MODE: NULL
    STARTS: 2006-02-09 10:41:23
    ENDS: NULL
    STATUS: ENABLED
    ON_COMPLETION: DROP
    CREATED: 2006-02-09 14:35:35
    LAST_ALTERED: 2006-02-09 14:41:23
    LAST_EXECUTED: NULL
    EVENT_COMMENT: Saves total number of sessions and
                   clears the table once per day.
1 row in set (0.50 sec)

```

Important: The times displayed by the `STARTS`, `ENDS`, and `LAST_EXECUTED` columns are currently given in terms of Universal Time (GMT or UTC), regardless of the server's time zone setting. (The same is true for the `starts`, `ends`, and `last_executed` columns of the `mysql.event` table and the `Starts` and `Ends` columns in the output of `SHOW [FULL] EVENTS`.) The `CREATED` and `LAST_ALTERED` columns use the server time zone (as do the `created` and `last_altered` columns of the `mysql.event` table).

For example, the `e_daily` event shown previously was created on a computer in Brisbane, Australia, at 14:35:35 on the 9th of February, 2006, Eastern Australia Standard Time, which can also be expressed as the `GMT+10.00` time zone. The event definition was updated (using `ALTER EVENT` as shown earlier in this section) a few minutes later, at 14:41:23. These are the values displayed for `CREATED` and `LAST_ALTERED`. The event is scheduled to begin executing 6 hours later — that is, at 20:41:23 on the same date, local time. Subtracting 10 hours from this to obtain Universal Time yields 10:41:23, and it is this value that is shown for `STARTS`.

This use of Universal Time should not be relied upon in applications, as it is expected to change to server local time in an upcoming MySQL release. ([Bug#16420](http://bugs.mysql.com/16420) [http://bugs.mysql.com/16420])

See also [Section 13.5.4.15](#), “`SHOW EVENTS`”.

22.21. The INFORMATION_SCHEMA FILES Table

The `FILES` table provides information about the files in which MySQL NDB tables are stored.

INFORMATION_SCHEMA Name	SHOW Name	Remarks
<code>FILE_ID</code>		MySQL extension
<code>FILE_NAME</code>		MySQL extension
<code>FILE_TYPE</code>		MySQL extension
<code>TABLESPACE_NAME</code>		MySQL extension
<code>TABLE_CATALOG</code>		MySQL extension
<code>TABLE_SCHEMA</code>		MySQL extension
<code>TABLE_NAME</code>		MySQL extension
<code>LOGFILE_GROUP_NAME</code>		MySQL extension
<code>LOGFILE_GROUP_NUMBER</code>		MySQL extension
<code>ENGINE</code>		MySQL extension
<code>FULLTEXT_KEYS</code>		MySQL extension
<code>DELETED_ROWS</code>		MySQL extension
<code>UPDATE_COUNT</code>		MySQL extension

FREE_EXTENTS		MySQL extension
TOTAL_EXTENTS		MySQL extension
EXTENT_SIZE		MySQL extension
INITIAL_SIZE		MySQL extension
MAXIMUM_SIZE		MySQL extension
AUTOEXTEND_SIZE		MySQL extension
CREATION_TIME		MySQL extension
LAST_UPDATE_TIME		MySQL extension
LAST_ACCESS_TIME		MySQL extension
RECOVER_TIME		MySQL extension
TRANSACTION_COUNTER		MySQL extension
VERSION		MySQL extension
ROW_FORMAT		MySQL extension
TABLE_ROWS		MySQL extension
AVG_ROW_LENGTH		MySQL extension
DATA_LENGTH		MySQL extension
MAX_DATA_LENGTH		MySQL extension
INDEX_LENGTH		MySQL extension
DATA_FREE		MySQL extension
CREATE_TIME		MySQL extension
UPDATE_TIME		MySQL extension
CHECK_TIME		MySQL extension
CHECKSUM		MySQL extension
STATUS		MySQL extension
EXTRA		MySQL extension

Notes:

- `FILE_ID` column values are auto-generated.
- `FILE_NAME` is the name of an `UNDO` logfile created by `CREATE LOGFILE GROUP` or `ALTER LOGFILE GROUP`, or of a datafile created by `CREATE TABLESPACE` or `ALTER TABLESPACE`.
- `FILE_TYPE` is one of the values `UNDOFILE` or `DATAFILE`.
- `TABLESPACE_NAME` is the name of the tablespace with which the file is associated.
- In MySQL 5.1, the value of the `TABLESPACE_CATALOG` column is always `NULL`.
- `TABLE_NAME` is the name of the Disk Data table with which the file is associated, if any.
- The `LOGFILE_GROUP_NAME` column gives the name of the logfile group to which the logfile or datafile belongs.
- For an `UNDO` logfile, the `LOGFILE_GROUP_NUMBER` contains the auto-generated ID number of the logfile group to which the logfile belongs.

- For a MySQL Cluster Disk Data logfile or datafile, the value of the `ENGINE` column is always `NDB` or `NDBCLUSTER`.
- For a MySQL Cluster Disk Data logfile or datafile, the value of the `FULLTEXT_KEYS` column is always empty.
- The `FREE_EXTENTS` column displays the number of extents which have not yet been used by the file. The `TOTAL_EXTENTS` column show the total number of extents allocated to the file.

The difference between these two columns is the number of extents currently in use by the file:

```
SELECT TOTAL_EXTENTS - FREE_EXTENTS AS extents_used
FROM INFORMATION_SCHEMA.FILES
WHERE FILE_NAME = 'myfile.dat';
```

You can approximate the amount of disk space in use by the file by multiplying this difference by the value of the `EXTENT_SIZE` column, which gives the size of an extent for the file in bytes:

```
SELECT (TOTAL_EXTENTS - FREE_EXTENTS) * EXTENT_SIZE AS bytes_used
FROM INFORMATION_SCHEMA.FILES
WHERE FILE_NAME = 'myfile.dat';
```

Similarly, you can estimate the amount of space that remains available in a given file by multiplying `FREE_EXTENTS` by `EXTENT_SIZE`:

```
SELECT FREE_EXTENTS * EXTENT_SIZE AS bytes_free
FROM INFORMATION_SCHEMA.FILES
WHERE FILE_NAME = 'myfile.dat';
```

Important: The byte values produced by the preceding queries are approximations only, and their precision is inversely proportional to the value of `EXTENT_SIZE`. That is, the larger `EXTENT_SIZE` becomes, the less accurate the approximations are.

It is also important to remember that once an extent is used, it cannot be freed again without dropping the datafile of which it is a part. This means that deletes from a Disk Data table do *not* release disk space.

The extent size can be set in a `CREATE TABLESPACE` statement. See [Section 13.1.9, “CREATE TABLESPACE Syntax”](#), for more information.

- The `INITIAL_SIZE` column shows the size in bytes of the file. This is the same value that was used in the `INITIAL_SIZE` clause of the `CREATE LOGFILE GROUP`, `ALTER LOGFILE GROUP`, `CREATE TABLESPACE`, or `ALTER TABLESPACE` statement used to create the file.

For MySQL 5.1 Cluster Disk Data files, the value of the `MAXIMUM_SIZE` column is always the same as `INITIAL_SIZE`, and the `AUTOEXTEND_SIZE` column is always empty.

- The `CREATION_TIME` column shows the date and time when the file was created. The `LAST_UPDATE_TIME` column displays the date and time when the file was last modified. The `LAST_ACCESSED` column provides the date and time when the file was last accessed by the server.

Currently, the values of these columns are as reported by the operating system, and are not supplied by the `NDB` storage engine. Where no value is provided by the operating system, these columns display `0000-00-00 00:00:00`.

- For MySQL Cluster Disk Data files, the value of the `RECOVER_TIME` and `TRANSACTION_COUNTER` columns is always `0`.
- For MySQL 5.1 Cluster Disk Data files, the following columns are always `NULL`:

- `VERSION`
 - `ROW_FORMAT`
 - `TABLE_ROWS`
 - `AVG_ROW_LENGTH`
 - `DATA_LENGTH`
 - `MAX_DATA_LENGTH`
 - `INDEX_LENGTH`
 - `DATA_FREE`
 - `CREATE_TIME`
 - `UPDATE_TIME`
 - `CHECK_TIME`
 - `CHECKSUM`
- For MySQL Cluster Disk Data files, the value of the `STATUS` column is always `NORMAL`.
 - For MySQL Cluster Disk Data files, the `EXTRA` column shows which data node the file belongs to, as each data node has its own copy of the file. For example, suppose you use this statement on a MySQL Cluster with four data nodes:

```
CREATE LOGFILE GROUP mygroup
  ADD UNDOFILE 'new_undo.dat'
  INITIAL_SIZE 2G
  ENGINE NDB;
```

After running the `CREATE LOGFILE GROUP` statement successfully, you should see a result similar to the one shown here for this query against the `FILES` table:

```
mysql> SELECT LOGFILE_GROUP_NAME, FILE_TYPE, EXTRA
-> FROM INFORMATION_SCHEMA.FILES
-> WHERE FILE_NAME = 'new_undo.dat';
```

LOGFILE_GROUP_NAME	FILE_TYPE	EXTRA
mygroup	UNDO FILE	CLUSTER_NODE=3
mygroup	UNDO FILE	CLUSTER_NODE=4
mygroup	UNDO FILE	CLUSTER_NODE=5
mygroup	UNDO FILE	CLUSTER_NODE=6

```
4 rows in set (0.01 sec)
```

- The `FILES` table is a non-standard table. It was added in MySQL 5.1.6.
- There are no `SHOW` commands associated with the `FILES` table.
- For additional examples using the `FILES` table to obtain information about Cluster Disk Data tables, see [Section 15.11, “MySQL Cluster Disk Data Storage”](#).

22.22. The INFORMATION_SCHEMA PROCESSLIST Ta-

ble

The `PROCESSLIST` table provides information about which threads are running.

INFORMATION_SCHEMA Name	SHOW Name	Remarks
ID	Id	MySQL extension
USER	User	MySQL extension
HOST	Host	MySQL extension
DB	db	MySQL extension
COMMAND	Command	MySQL extension
TIME	Time	MySQL extension
STATE	State	MySQL extension
INFO	Info	MySQL extension

For an extensive description of the table columns, see [Section 13.5.4.23, “SHOW PROCESSLIST Syntax”](#).

Notes:

- The `PROCESSLIST` table is a non-standard table. It was added in MySQL 5.1.7.
- Like the output from the corresponding `SHOW` statement, the `PROCESSLIST` table will only show information about your own threads, unless you have the `PROCESS` privilege, in which case you will see information about other threads, too. As an anonymous user, you cannot see any rows at all.
- If an SQL statement refers to `INFORMATION_SCHEMA.PROCESSLIST`, then MySQL will populate the entire table once, when statement execution begins, so there is read consistency during the statement. There is no read consistency for a multi-statement transaction, though.

The following statements are equivalent:

```
SELECT * FROM INFORMATION_SCHEMA.PROCESSLIST
SHOW PROCESSLIST
```

22.23. The INFORMATION_SCHEMA REFERENTIAL_CONSTRAINTS Table

The `REFERENTIAL_CONSTRAINTS` table provides information about foreign keys.

INFORMATION_SCHEMA Name	SHOW Name	Remarks
CONSTRAINT_CATALOG		NULL
CONSTRAINT_SCHEMA		
CONSTRAINT_NAME		
UNIQUE_CONSTRAINT_CATALOG		NULL
UNIQUE_CONSTRAINT_SCHEMA		
UNIQUE_CONSTRAINT_NAME		
MATCH_OPTION		

UPDATE_RULE		
DELETE_RULE		
TABLE_NAME		

Notes:

- The REFERENTIAL_CONSTRAINTS table was added in MySQL 5.1.10.
- TABLE_NAME has the same value as TABLE_NAME in INFORMATION_SCHEMA.TABLE_CONSTRAINTS.
- CONSTRAINT_SCHEMA and CONSTRAINT_NAME identify the foreign key.
- UNIQUE_CONSTRAINT_SCHEMA and UNIQUE_CONSTRAINT_NAME identify the referenced key.
- The only valid value at this time for MATCH_OPTION is NONE.
- The possible values for UPDATE_RULE or DELETE_RULE are CASCADE, SET NULL, SET DEFAULT, RESTRICT, NO ACTION.

22.24. The INFORMATION_SCHEMA GLOBAL_STATUS and SESSION_STATUS Tables

The GLOBAL_STATUS and SESSION_STATUS tables provide information about server status variables. Their contents correspond to the information produced by the SHOW GLOBAL STATUS and SHOW SESSION STATUS statements (see Section 13.5.4.25, “SHOW STATUS Syntax”).

INFORMATION_SCHEMA Name	SHOW Name	Remarks
VARIABLE_NAME	Variable_name	
VARIABLE_VALUE	Value	

Notes:

- The GLOBAL_STATUS and SESSION_STATUS tables were added in MySQL 5.1.12.
- The VARIABLE_VALUE column has the BIGINT type. The few status variables that have non-integer values are coerced to BIGINT values.

22.25. The INFORMATION_SCHEMA GLOBAL_VARIABLES and SESSION_VARIABLES Tables

The GLOBAL_VARIABLES and SESSION_VARIABLES tables provide information about server status variables. Their contents correspond to the information produced by the SHOW GLOBAL VARIABLES and SHOW SESSION VARIABLES statements (see Section 13.5.4.29, “SHOW VARIABLES Syntax”).

INFORMATION_SCHEMA Name	SHOW Name	Remarks
-------------------------	-----------	---------

<code>VARIABLE_NAME</code>	Variable_name	
<code>VARIABLE_VALUE</code>	Value	

Notes:

- The `GLOBAL_VARIABLES` and `SESSION_VARIABLES` tables were added in MySQL 5.1.12.

22.26. Other `INFORMATION_SCHEMA` Tables

We intend to implement additional `INFORMATION_SCHEMA` tables. In particular, we acknowledge the need for the `PARAMETERS` table.

22.27. Extensions to `SHOW` Statements

Some extensions to `SHOW` statements accompany the implementation of `INFORMATION_SCHEMA`:

- `SHOW` can be used to get information about the structure of `INFORMATION_SCHEMA` itself.
- Several `SHOW` statements accept a `WHERE` clause that provides more flexibility in specifying which rows to display.

`INFORMATION_SCHEMA` is an information database, so its name is included in the output from `SHOW DATABASES`. Similarly, `SHOW TABLES` can be used with `INFORMATION_SCHEMA` to obtain a list of its tables:

```
mysql> SHOW TABLES FROM INFORMATION_SCHEMA;
+-----+
| Tables_in_information_schema |
+-----+
| CHARACTER_SETS              |
| COLLATIONS                   |
| COLLATION_CHARACTER_SET_APPLICABILITY |
| COLUMNS                     |
| COLUMN_PRIVILEGES           |
| ENGINES                      |

| VIEWS                        |
+-----+
22 rows in set (0.04 sec)
```

`SHOW COLUMNS` and `DESCRIBE` can display information about the columns in individual `INFORMATION_SCHEMA` tables.

Several `SHOW` statements have been extended to allow a `WHERE` clause:

```

SHOW CHARACTER SET
SHOW COLLATION
SHOW COLUMNS
SHOW DATABASES
SHOW FUNCTION STATUS
SHOW KEYS
SHOW OPEN TABLES
SHOW PROCEDURE STATUS
SHOW STATUS
SHOW TABLE STATUS
SHOW TABLES
SHOW VARIABLES

```

The `WHERE` clause, if present, is evaluated against the column names displayed by the `SHOW` statement. For example, the `SHOW CHARACTER SET` statement produces these output columns:

```

mysql> SHOW CHARACTER SET;
+-----+-----+-----+-----+
| Charset | Description | Default collation | Maxlen |
+-----+-----+-----+-----+
| big5    | Big5 Traditional Chinese | big5_chinese_ci | 2 |
| dec8    | DEC West European | dec8_swedish_ci | 1 |
| cp850   | DOS West European | cp850_general_ci | 1 |
| hp8     | HP West European | hp8_english_ci | 1 |
| koi8r   | KOI8-R Relcom Russian | koi8r_general_ci | 1 |
| latin1  | cp1252 West European | latin1_swedish_ci | 1 |
| latin2  | ISO 8859-2 Central European | latin2_general_ci | 1 |
| ...

```

To use a `WHERE` clause with `SHOW CHARACTER SET`, you would refer to those column names. As an example, the following statement displays information about character sets for which the default collation contains the string `'japanese'`:

```

mysql> SHOW CHARACTER SET WHERE `Default collation` LIKE '%japanese%';
+-----+-----+-----+-----+
| Charset | Description | Default collation | Maxlen |
+-----+-----+-----+-----+
| ujis    | EUC-JP Japanese | ujis_japanese_ci | 3 |
| sjis    | Shift-JIS Japanese | sjis_japanese_ci | 2 |
| cp932   | SJIS for Windows Japanese | cp932_japanese_ci | 2 |
| eucjpms | UJIS for Windows Japanese | eucjpms_japanese_ci | 3 |
+-----+-----+-----+-----+

```

This statement displays the multi-byte character sets:

```

mysql> SHOW CHARACTER SET WHERE Maxlen > 1;
+-----+-----+-----+-----+
| Charset | Description | Default collation | Maxlen |
+-----+-----+-----+-----+
| big5    | Big5 Traditional Chinese | big5_chinese_ci | 2 |
| ujis    | EUC-JP Japanese | ujis_japanese_ci | 3 |
| sjis    | Shift-JIS Japanese | sjis_japanese_ci | 2 |
| euckr   | EUC-KR Korean | euckr_korean_ci | 2 |
| gb2312  | GB2312 Simplified Chinese | gb2312_chinese_ci | 2 |
| gbk     | GBK Simplified Chinese | gbk_chinese_ci | 2 |
| utf8    | UTF-8 Unicode | utf8_general_ci | 3 |
| ucs2    | UCS-2 Unicode | ucs2_general_ci | 2 |
| cp932   | SJIS for Windows Japanese | cp932_japanese_ci | 2 |
| eucjpms | UJIS for Windows Japanese | eucjpms_japanese_ci | 3 |
+-----+-----+-----+-----+

```

Chapter 23. Precision Math

MySQL 5.1 provides support for precision math: numeric value handling that results in extremely accurate results and a high degree control over invalid values. Precision math is based on these two features:

- SQL modes that control how strict the server is about accepting or rejecting invalid data.
- The MySQL library for fixed-point arithmetic.

These features have several implications for numeric operations:

- **Precise calculations:** For exact-value numbers, calculations do not introduce floating-point errors. Instead, exact precision is used. For example, a number such as `.0001` is treated as an exact value rather than as an approximation, and summing it 10,000 times produces a result of exactly `1`, not a value that merely “close” to 1.
- **Well-defined rounding behavior:** For exact-value numbers, the result of `ROUND()` depends on its argument, not on environmental factors such as how the underlying C library works.
- **Platform independence:** Operations on exact numeric values are the same across different platforms such as Windows and Unix.
- **Control over handling of invalid values:** Overflow and division by zero are detectable and can be treated as errors. For example, you can treat a value that is too large for a column as an error rather than having the value truncated to lie within the range of the column's data type. Similarly, you can treat division by zero as an error rather than as an operation that produces a result of `NULL`. The choice of which approach to take is determined by the setting of the `sql_mode` system variable.

An important result of these features is that MySQL 5.1 provides a high degree of compliance with standard SQL.

The following discussion covers several aspects of how precision math works (including possible incompatibilities with older applications). At the end, some examples are given that demonstrate how MySQL 5.1 handles numeric operations precisely. For information about using the `sql_mode` system variable to control the SQL mode, see [Section 5.2.6, “SQL Modes”](#).

23.1. Types of Numeric Values

The scope of precision math for exact-value operations includes the exact-value data types (`DECIMAL` and integer types) and exact-value numeric literals. Approximate-value data types and numeric literals still are handled as floating-point numbers.

Exact-value numeric literals have an integer part or fractional part, or both. They may be signed. Examples: `1`, `.2`, `3.4`, `-5`, `-6.78`, `+9.10`.

Approximate-value numeric literals are represented in scientific notation with a mantissa and exponent. Either or both parts may be signed. Examples: `1.2E3`, `1.2E-3`, `-1.2E3`, `-1.2E-3`.

Two numbers that look similar need not be both exact-value or both approximate-value. For example, `2.34` is an exact-value (fixed-point) number, whereas `2.34E0` is an approximate-value (floating-point) number.

The `DECIMAL` data type is a fixed-point type and calculations are exact. In MySQL, the `DECIMAL` type

has several synonyms: `NUMERIC`, `DEC`, `FIXED`. The integer types also are exact-value types.

The `FLOAT` and `DOUBLE` data types are floating-point types and calculations are approximate. In MySQL, types that are synonymous with `FLOAT` or `DOUBLE` are `DOUBLE PRECISION` and `REAL`.

23.2. DECIMAL Data Type Changes

This section discusses the characteristics of the `DECIMAL` data type (and its synonyms) in MySQL 5.1, with particular regard to the following topics:

- Maximum number of digits
- Storage format
- Storage requirements
- The non-standard MySQL extension to the upper range of `DECIMAL` columns

Possible incompatibilities with applications that are written for older versions of MySQL are noted throughout this section.

The declaration syntax for a `DECIMAL` column is `DECIMAL(M, D)`. The ranges of values for the arguments in MySQL 5.1 are as follows:

- *M* is the maximum number of digits (the precision). It has a range of 1 to 65. (Older versions of MySQL allowed a range of 1 to 254.)
- *D* is the number of digits to the right of the decimal point (the scale). It has a range of 0 to 30 and must be no larger than *M*.

The maximum value of 65 for *M* means that calculations on `DECIMAL` values are accurate up to 65 digits. This limit of 65 digits of precision also applies to exact-value numeric literals, so the maximum range of such literals is different from before. (In older versions of MySQL, decimal values could have up to 254 digits. However, calculations were done using floating-point and thus were approximate, not exact.)

Values for `DECIMAL` columns in MySQL 5.1 are stored using a binary format that packs nine decimal digits into four bytes. The storage requirements for the integer and fractional parts of each value are determined separately. Each multiple of nine digits requires four bytes, and any digits left over require some fraction of four bytes. For example, a `DECIMAL(18, 9)` column has nine digits on either side of the decimal point, so the integer part and the fractional part each require four bytes. A `DECIMAL(20, 10)` column has ten digits on either side of the decimal point. Each part requires four bytes for nine of the digits, and one byte for the remaining digit.

The storage required for leftover digits is given by the following table:

Leftover Digits	Number of Bytes
0	0
1	1
2	1
3	2
4	2
5	3

6	3
7	4
8	4
9	4

Unlike some older versions of MySQL (prior to 5.0.3), `DECIMAL` columns in MySQL 5.1 do not store a leading `+` character or leading `0` digits. If you insert `+0003.1` into a `DECIMAL(5,1)` column, it is stored as `3.1`. Applications that rely on the older behavior must be modified to account for this change.

`DECIMAL` columns in MySQL 5.1 do not allow values larger than the range implied by the column definition. For example, a `DECIMAL(3,0)` column supports a range of `-999` to `999`. A `DECIMAL(M,D)` column allows at most $M - D$ digits to the left of the decimal point. This is not compatible with applications relying on older versions of MySQL that allowed storing an extra digit in lieu of a `+` sign.

The SQL standard requires that the precision of `NUMERIC(M,D)` be *exactly* M digits. For `DECIMAL(M,D)`, the standard requires a precision of at least M digits but allows more. In MySQL, `DECIMAL(M,D)` and `NUMERIC(M,D)` are the same, and both have a precision of exactly M digits.

For more detailed information about porting applications that rely on the old treatment of the `DECIMAL` data type, see the *MySQL 5.0 Reference Manual*.

23.3. Expression Handling

With precision math, exact-value numbers are used as given whenever possible. For example, numbers in comparisons are used exactly as given without a change in value. In strict SQL mode, for `INSERT` into a column with an exact data type (`DECIMAL` or integer), a number is inserted with its exact value if it is within the column range. When retrieved, the value should be the same as what was inserted. (Without strict mode, truncation for `INSERT` is allowable.)

Handling of a numeric expression depends on what kind of values the expression contains:

- If any approximate values are present, the expression is approximate and is evaluated using floating-point arithmetic.
- If no approximate values are present, the expression contains only exact values. If any exact value contains a fractional part (a value following the decimal point), the expression is evaluated using `DECIMAL` exact arithmetic and has a precision of 65 digits. (The term “exact” is subject to the limits of what can be represented in binary. For example, $1.0/3.0$ can be approximated in decimal notation as `.333...`, but not written as an exact number, so $(1.0/3.0)*3.0$ does not evaluate to exactly `1.0`.)
- Otherwise, the expression contains only integer values. The expression is exact and is evaluated using integer arithmetic and has a precision the same as `BIGINT` (64 bits).

If a numeric expression contains any strings, they are converted to double-precision floating-point values and the expression is approximate.

Inserts into numeric columns are affected by the SQL mode, which is controlled by the `sql_mode` system variable. (See [Section 5.2.6, “SQL Modes”](#).) The following discussion mentions strict mode (selected by the `STRICT_ALL_TABLES` or `STRICT_TRANS_TABLES` mode values) and `ERROR_FOR_DIVISION_BY_ZERO`. To turn on all restrictions, you can simply use `TRADITIONAL` mode, which includes both strict mode values and `ERROR_FOR_DIVISION_BY_ZERO`:

```
mysql> SET sql_mode='TRADITIONAL';
```

If a number is inserted into an exact type column ([DECIMAL](#) or integer), it is inserted with its exact value if it is within the column range.

If the value has too many digits in the fractional part, rounding occurs and a warning is generated. Rounding is done as described in [Section 23.4, “Rounding Behavior”](#).

If the value has too many digits in the integer part, it is too large and is handled as follows:

- If strict mode is not enabled, the value is truncated to the nearest legal value and a warning is generated.
- If strict mode is enabled, an overflow error occurs.

Underflow is not detected, so underflow handling is undefined.

By default, division by zero produces a result of [NULL](#) and no warning. With the [ERROR_FOR_DIVISION_BY_ZERO](#) SQL mode enabled, MySQL handles division by zero differently:

- If strict mode is not enabled, a warning occurs.
- If strict mode is enabled, inserts and updates involving division by zero are prohibited, and an error occurs.

In other words, inserts and updates involving expressions that perform division by zero can be treated as errors, but this requires [ERROR_FOR_DIVISION_BY_ZERO](#) in addition to strict mode.

Suppose that we have this statement:

```
INSERT INTO t SET i = 1/0;
```

This is what happens for combinations of strict and [ERROR_FOR_DIVISION_BY_ZERO](#) modes:

sql_mode Value	Result
' ' (Default)	No warning, no error; i is set to NULL .
strict	No warning, no error; i is set to NULL .
ERROR_FOR_DIVISION_BY_ZERO	Warning, no error; i is set to NULL .
strict, ERROR_FOR_DIVISION_BY_ZERO	Error condition; no row is inserted.

For inserts of strings into numeric columns, conversion from string to number is handled as follows if the string has non-numeric contents:

- A string that does not begin with a number cannot be used as a number and produces an error in strict mode, or a warning otherwise. *This includes the empty string.*
- A string that begins with a number can be converted, but the trailing non-numeric portion is truncated. If the truncated portion contains anything other than spaces, this produces an error in strict mode, or a warning otherwise.

23.4. Rounding Behavior

This section discusses precision math rounding for the `ROUND()` function and for inserts into columns with exact-value types (`DECIMAL` and integer).

The `ROUND()` function rounds differently depending on whether its argument is exact or approximate:

- For exact-value numbers, `ROUND()` uses the “round half up” rule: A value with a fractional part of .5 or greater is rounded up to the next integer if positive or down to the next integer if negative. (In other words, it is rounded away from zero.) A value with a fractional part less than .5 is rounded down to the next integer if positive or up to the next integer if negative.
- For approximate-value numbers, the result depends on the C library. On many systems, this means that `ROUND()` uses the “round to nearest even” rule: A value with any fractional part is rounded to the nearest even integer.

The following example shows how rounding differs for exact and approximate values:

```
mysql> SELECT ROUND(2.5), ROUND(25E-1);
+-----+-----+
| ROUND(2.5) | ROUND(25E-1) |
+-----+-----+
| 3          | 2            |
+-----+-----+
```

For inserts into a `DECIMAL` or integer column, the target is an exact data type, so rounding uses “round half up,” regardless of whether the value to be inserted is exact or approximate:

```
mysql> CREATE TABLE t (d DECIMAL(10,0));
Query OK, 0 rows affected (0.00 sec)

mysql> INSERT INTO t VALUES(2.5),(2.5E0);
Query OK, 2 rows affected, 2 warnings (0.00 sec)
Records: 2 Duplicates: 0 Warnings: 2

mysql> SELECT d FROM t;
+-----+
| d     |
+-----+
| 3     |
| 3     |
+-----+
```

23.5. Precision Math Examples

This section provides some examples that show precision math query results in MySQL 5.1.

Example 1. Numbers are used with their exact value as given when possible:

```
mysql> SELECT .1 + .2 = .3;
+-----+
| .1 + .2 = .3 |
+-----+
| 1            |
+-----+
```

For floating-point values, results are inexact:

```
mysql> SELECT .1E0 + .2E0 = .3E0;
+-----+
| .1E0 + .2E0 = .3E0 |
+-----+
| 0                    |
+-----+
```

```
+-----+
```

Another way to see the difference in exact and approximate value handling is to add a small number to a sum many times. Consider the following stored procedure, which adds `.0001` to a variable 1,000 times.

```
CREATE PROCEDURE p ()
BEGIN
  DECLARE i INT DEFAULT 0;
  DECLARE d DECIMAL(10,4) DEFAULT 0;
  DECLARE f FLOAT DEFAULT 0;
  WHILE i < 10000 DO
    SET d = d + .0001;
    SET f = f + .0001E0;
    SET i = i + 1;
  END WHILE;
  SELECT d, f;
END;
```

The sum for both `d` and `f` logically should be 1, but that is true only for the decimal calculation. The floating-point calculation introduces small errors:

```
+-----+
| d      | f      |
+-----+
| 1.0000 | 0.999999999999991 |
+-----+
```

Example 2. Multiplication is performed with the scale required by standard SQL. That is, for two numbers `X1` and `X2` that have scale `S1` and `S2`, the scale of the result is `S1 + S2`:

```
mysql> SELECT .01 * .01;
+-----+
| .01 * .01 |
+-----+
| 0.0001    |
+-----+
```

Example 3. Rounding behavior is well-defined:

Rounding behavior (for example, with the `ROUND()` function) is independent of the implementation of the underlying C library, which means that results are consistent from platform to platform.

Rounding for exact-value columns (`DECIMAL` and integer) and exact-valued numbers uses the “round half up” rule. Values with a fractional part of `.5` or greater are rounded away from zero to the nearest integer, as shown here:

```
mysql> SELECT ROUND(2.5), ROUND(-2.5);
+-----+
| ROUND(2.5) | ROUND(-2.5) |
+-----+
| 3          | -3          |
+-----+
```

However, rounding for floating-point values uses the C library, which on many systems uses the “round to nearest even” rule. Values with any fractional part on such systems are rounded to the nearest even integer:

```
mysql> SELECT ROUND(2.5E0), ROUND(-2.5E0);
+-----+
| ROUND(2.5E0) | ROUND(-2.5E0) |
+-----+
| 2            | -2            |
+-----+
```

Example 4. In strict mode, inserting a value that is too large results in overflow and causes an error,

rather than truncation to a legal value.

When MySQL is not running in strict mode, truncation to a legal value occurs:

```
mysql> SET sql_mode='';
Query OK, 0 rows affected (0.00 sec)

mysql> CREATE TABLE t (i TINYINT);
Query OK, 0 rows affected (0.01 sec)

mysql> INSERT INTO t SET i = 128;
Query OK, 1 row affected, 1 warning (0.00 sec)

mysql> SELECT i FROM t;
+-----+
| i     |
+-----+
| 127  |
+-----+
1 row in set (0.00 sec)
```

However, an overflow condition occurs if strict mode is in effect:

```
mysql> SET sql_mode='STRICT_ALL_TABLES';
Query OK, 0 rows affected (0.00 sec)

mysql> CREATE TABLE t (i TINYINT);
Query OK, 0 rows affected (0.00 sec)

mysql> INSERT INTO t SET i = 128;
ERROR 1264 (22003): Out of range value adjusted for column 'i' at row 1

mysql> SELECT i FROM t;
Empty set (0.00 sec)
```

Example 5: In strict mode and with `ERROR_FOR_DIVISION_BY_ZERO` set, division by zero causes an error, and not a result of `NULL`.

In non-strict mode, division by zero has a result of `NULL`:

```
mysql> SET sql_mode='';
Query OK, 0 rows affected (0.01 sec)

mysql> CREATE TABLE t (i TINYINT);
Query OK, 0 rows affected (0.00 sec)

mysql> INSERT INTO t SET i = 1 / 0;
Query OK, 1 row affected (0.00 sec)

mysql> SELECT i FROM t;
+-----+
| i     |
+-----+
| NULL  |
+-----+
1 row in set (0.03 sec)
```

However, division by zero is an error if the proper SQL modes are in effect:

```
mysql> SET sql_mode='STRICT_ALL_TABLES,ERROR_FOR_DIVISION_BY_ZERO';
Query OK, 0 rows affected (0.00 sec)

mysql> CREATE TABLE t (i TINYINT);
Query OK, 0 rows affected (0.00 sec)

mysql> INSERT INTO t SET i = 1 / 0;
ERROR 1365 (22012): Division by 0

mysql> SELECT i FROM t;
Empty set (0.01 sec)
```

Example 6. Prior to MySQL 5.0.3 (before precision math was introduced), exact-value and approxim-

ate-value literals both are converted to double-precision floating-point values:

```
mysql> SELECT VERSION();
+-----+
| VERSION() |
+-----+
| 4.1.18-log |
+-----+
1 row in set (0.01 sec)

mysql> CREATE TABLE t SELECT 2.5 AS a, 25E-1 AS b;
Query OK, 1 row affected (0.07 sec)
Records: 1 Duplicates: 0 Warnings: 0

mysql> DESCRIBE t;
+-----+-----+-----+-----+-----+-----+
| Field | Type           | Null | Key | Default | Extra |
+-----+-----+-----+-----+-----+-----+
| a     | double(3,1)   |      |     | 0.0     |      |
| b     | double        |      |     | 0       |      |
+-----+-----+-----+-----+-----+-----+
2 rows in set (0.04 sec)
```

As of MySQL 5.0.3, the approximate-value literal still is converted to floating-point, but the exact-value literal is handled as `DECIMAL`:

```
mysql> SELECT VERSION();
+-----+
| VERSION() |
+-----+
| 5.1.6-alpha-log |
+-----+
1 row in set (0.11 sec)

mysql> CREATE TABLE t SELECT 2.5 AS a, 25E-1 AS b;
Query OK, 1 row affected (0.01 sec)
Records: 1 Duplicates: 0 Warnings: 0

mysql> DESCRIBE t;
+-----+-----+-----+-----+-----+-----+
| Field | Type                | Null | Key | Default | Extra |
+-----+-----+-----+-----+-----+-----+
| a     | decimal(2,1) unsigned | NO   |     | 0.0     |      |
| b     | double              | NO   |     | 0       |      |
+-----+-----+-----+-----+-----+-----+
2 rows in set (0.01 sec)
```

Example 7. If the argument to an aggregate function is an exact numeric type, the result is also an exact numeric type, with a scale at least that of the argument.

Consider these statements:

```
mysql> CREATE TABLE t (i INT, d DECIMAL, f FLOAT);
mysql> INSERT INTO t VALUES(1,1,1);
mysql> CREATE TABLE y SELECT AVG(i), AVG(d), AVG(f) FROM t;
```

Result before MySQL 5.0.3 (prior to the introduction of precision math in MySQL):

```
mysql> DESCRIBE y;
+-----+-----+-----+-----+-----+-----+
| Field | Type           | Null | Key | Default | Extra |
+-----+-----+-----+-----+-----+-----+
| AVG(i) | double(17,4)  | YES  |     | NULL    |      |
| AVG(d) | double(17,4)  | YES  |     | NULL    |      |
| AVG(f) | double        | YES  |     | NULL    |      |
+-----+-----+-----+-----+-----+-----+
```

The result is a double no matter the argument type.

Result as of MySQL 5.0.3:

```
mysql> DESCRIBE y;
```

Field	Type	Null	Key	Default	Extra
AVG(i)	decimal(14,4)	YES		NULL	
AVG(d)	decimal(14,4)	YES		NULL	
AVG(f)	double	YES		NULL	

The result is a double only for the floating-point argument. For exact type arguments, the result is also an exact type.

Chapter 24. APIs and Libraries

This chapter describes the APIs available for MySQL, where to get them, and how to use them. The C API is the most extensively covered, because it was developed by the MySQL team, and is the basis for most of the other APIs. This chapter also covers the `libmysqld` library (the embedded server), as well as some programs that are useful for application developers.

24.1. libmysqld, the Embedded MySQL Server Library

24.1.1. Overview of the Embedded MySQL Server Library

The embedded MySQL server library makes it possible to run a full-featured MySQL server inside a client application. The main benefits are increased speed and more simple management for embedded applications.

The embedded server library is based on the client/server version of MySQL, which is written in C/C++. Consequently, the embedded server also is written in C/C++. There is no embedded server available in other languages.

The API is identical for the embedded MySQL version and the client/server version. To change an old threaded application to use the embedded library, you normally only have to add calls to the following functions:

Function	When to Call
<code>mysql_server_init()</code>	Should be called before any other MySQL function is called, preferably early in the <code>main()</code> function.
<code>mysql_server_end()</code>	Should be called before your program exits.
<code>mysql_thread_init()</code>	Should be called in each thread you create that accesses MySQL.
<code>mysql_thread_end()</code>	Should be called before calling <code>pthread_exit()</code>

Then you must link your code with `libmysqld.a` instead of `libmysqlclient.a`.

The `mysql_server_XXX()` functions are also included in `libmysqlclient.a` to allow you to change between the embedded and the client/server version by just linking your application with the right library. See [Section 24.2.12.1](#), “`mysql_server_init()`”.

One difference between the embedded server and the standalone server is that for the embedded server, authentication for connections is disabled by default. To use authentication for the embedded server, specify the `--with-embedded-privilege-control` option when you invoke `configure` to configure your MySQL distribution.

24.1.2. Compiling Programs with `libmysqld`

To get a `libmysqld` library you should configure MySQL with the `--with-embedded-server` option. See [Section 2.9.2](#), “[Typical configure Options](#)”.

When you link your program with `libmysqld`, you must also include the system-specific `pthread` libraries and some libraries that the MySQL server uses. You can get the full list of libraries by executing `mysql_config --libmysqld-libs`.

The correct flags for compiling and linking a threaded program must be used, even if you do not directly call any thread functions in your code.

To compile a C program to include the necessary files to embed the MySQL server library into a compiled version of a program, use the GNU C compiler (`gcc`). The compiler will need to know where to find various files and need instructions on how to compile the program. The following example shows how a program could be compiled from the command line:

```
gcc mysql_test.c -o mysql_test -lz \  
`/usr/local/mysql/bin/mysql_config --include --libmysqld-libs`
```

Immediately following the `gcc` command is the name of the uncompiled C program file. After it, the `-o` option is given to indicate that the file name that follows is the name that the compiler is to give to the output file, the compiled program. The next line of code tells the compiler to obtain the location of the include files and libraries and other settings for the system on which it's compiled. Because of a problem with `mysql_config`, the option `-lz` (for compression) is added here. The `mysql_config` piece is contained in backticks, not single quotes.

24.1.3. Restrictions When Using the Embedded MySQL Server

The embedded server has the following limitations:

- No user-defined functions (UDFs).
- No stack trace on core dump.
- You cannot set this up as a master or a slave (no replication).
- Very large result sets may be unusable on low memory systems.
- You cannot connect to an embedded server from an outside process with sockets or TCP/IP. However, you can connect to an intermediate application, which in turn can connect to an embedded server on the behalf of a remote client or outside process.

Some of these limitations can be changed by editing the `mysql_embed.h` include file and recompiling MySQL.

24.1.4. Options with the Embedded Server

Any options that may be given with the `mysqld` server daemon, may be used with an embedded server library. Server options may be given in an array as an argument to the `mysql_server_init()`, which initializes the server. They also may be given in an option file like `my.cnf`. To specify an option file for a C program, use the `--defaults-file` option as one of the elements of the second argument of the `mysql_server_init()` function. See [Section 24.2.12.1](#), “`mysql_server_init()`”, for more information on the `mysql_server_init()` function.

Using option files can make it easier to switch between a client/server application and one where MySQL is embedded. Put common options under the `[server]` group. These are read by both MySQL versions. Client/server-specific options should go under the `[mysqld]` section. Put options specific to the embedded MySQL server library in the `[embedded]` section. Options specific to applications go under section labeled `[ApplicationName_SERVER]`. See [Section 4.3.2](#), “Using Option Files”.

24.1.5. Embedded Server Examples

These two example programs should work without any changes on a Linux or FreeBSD system. For other operating systems, minor changes are needed, mostly with file paths. These examples are designed to give enough details for you to understand the problem, without the clutter that is a necessary part of a real application. The first example is very straightforward. The second example is a little more advanced with some error checking. The first is followed by a command-line entry for compiling the program. The second is followed by a GNUmake file that may be used for compiling instead.

Example 1

test1_libmysqld.c

```
#include <stdio.h>
#include <stdlib.h>
#include <stdarg.h>
#include "mysql.h"

MYSQL *mysql;
MYSQL_RES *results;
MYSQL_ROW record;

static char *server_options[] = \
    { "mysql_test", "--defaults-file=my.cnf", NULL };
int num_elements = sizeof(server_options)/ sizeof(char *);

static char *server_groups[] = { "libmysqld_server",
    "libmysqld_client", NULL };

int main(void)
{
    mysql_server_init(num_elements, server_options, server_groups);
    mysql = mysql_init(NULL);
    mysql_options(mysql, MYSQL_READ_DEFAULT_GROUP, "libmysqld_client");
    mysql_options(mysql, MYSQL_OPT_USE_EMBEDDED_CONNECTION, NULL);

    mysql_real_connect(mysql, NULL,NULL,NULL, "database1", 0,NULL,0);

    mysql_query(mysql, "SELECT column1, column2 FROM table1");

    results = mysql_store_result(mysql);

    while((record = mysql_fetch_row(results))) {
        printf("%s - %s \n", record[0], record[1]);
    }

    mysql_free_result(results);
    mysql_close(mysql);
    mysql_server_end();

    return 0;
}
```

Here is the command line for compiling the above program:

```
gcc test1_libmysqld.c -o test1_libmysqld -lz \
    `~/usr/local/mysql/bin/mysql_config --include --libmysqld-libs`
```

Example 2

To try out the example, create an `test2_libmysqld` directory at the same level as the MySQL source directory. Save the `test2_libmysqld.c` source and the `GNUmakefile` in the directory, and run GNU `make` from inside the `test2_libmysqld` directory.

test2_libmysqld.c

```
/*
 * A simple example client, using the embedded MySQL server library
 */
```

```

#include <mysql.h>
#include <stdarg.h>
#include <stdio.h>
#include <stdlib.h>

MYSQL *db_connect(const char *dbname);
void db_disconnect(MYSQL *db);
void db_do_query(MYSQL *db, const char *query);

const char *server_groups[] = {
    "test2_libmysqld_SERVER", "embedded", "server", NULL
};

int
main(int argc, char **argv)
{
    MYSQL *one, *two;

    /* mysql_server_init() must be called before any other mysql
     * functions.
     *
     * You can use mysql_server_init(0, NULL, NULL), and it
     * initializes the server using groups = {
     *   "server", "embedded", NULL
     * }.
     *
     * In your $HOME/.my.cnf file, you probably want to put:
     [test2_libmysqld_SERVER]
     language = /path/to/source/of/mysql/sql/share/english
     *
     * You could, of course, modify argc and argv before passing
     * them to this function. Or you could create new ones in any
     * way you like. But all of the arguments in argv (except for
     * argv[0], which is the program name) should be valid options
     * for the MySQL server.
     *
     * If you link this client against the normal mysqlclient
     * library, this function is just a stub that does nothing.
     */
    mysql_server_init(argc, argv, (char **)server_groups);

    one = db_connect("test");
    two = db_connect(NULL);

    db_do_query(one, "SHOW TABLE STATUS");
    db_do_query(two, "SHOW DATABASES");

    mysql_close(two);
    mysql_close(one);

    /* This must be called after all other mysql functions */
    mysql_server_end();

    exit(EXIT_SUCCESS);
}

static void
die(MYSQL *db, char *fmt, ...)
{
    va_list ap;
    va_start(ap, fmt);
    vfprintf(stderr, fmt, ap);
    va_end(ap);
    (void)putc('\n', stderr);
    if (db)
        db_disconnect(db);
    exit(EXIT_FAILURE);
}

MYSQL *
db_connect(const char *dbname)
{
    MYSQL *db = mysql_init(NULL);
    if (!db)
        die(db, "mysql_init failed: no memory");
    /*
     * Notice that the client and server use separate group names.
     * This is critical, because the server does not accept the
     * client's options, and vice versa.
    */
}

```

```

*/
mysql_options(db, MYSQL_READ_DEFAULT_GROUP, "test2_libmysqld_CLIENT");
if (!mysql_real_connect(db, NULL, NULL, NULL, dbname, 0, NULL, 0))
    die(db, "mysql_real_connect failed: %s", mysql_error(db));

return db;
}

void
db_disconnect(MYSQL *db)
{
    mysql_close(db);
}

void
db_do_query(MYSQL *db, const char *query)
{
    if (mysql_query(db, query) != 0)
        goto err;

    if (mysql_field_count(db) > 0)
    {
        MYSQL_RES *res;
        MYSQL_ROW row, end_row;
        int num_fields;

        if (!(res = mysql_store_result(db)))
            goto err;
        num_fields = mysql_num_fields(res);
        while ((row = mysql_fetch_row(res)))
        {
            (void)fputs(">> ", stdout);
            for (end_row = row + num_fields; row < end_row; ++row)
                (void)printf("%s\t", row ? (char*)*row : "NULL");
            (void)fputc('\n', stdout);
        }
        (void)fputc('\n', stdout);
        mysql_free_result(res);
    }
    else
        (void)printf("Affected rows: %lld\n", mysql_affected_rows(db));

    return;

err:
    die(db, "db_do_query failed: %s [%s]", mysql_error(db), query);
}

```

GNUmakefile

```

# This assumes the MySQL software is installed in /usr/local/mysql
inc      := /usr/local/mysql/include/mysql
lib      := /usr/local/mysql/lib

# If you have not installed the MySQL software yet, try this instead
#inc     := $(HOME)/mysql-5.1/include
#lib     := $(HOME)/mysql-5.1/libmysqld

# FreeBSD
LDFLAGS += -pthread
else
# Assume Linux
LDLIBS += -lpthread
endif

# This works for simple one-file test programs
sources := $(wildcard *.c)
objects := $(patsubst %c,%o,$(sources))
targets := $(basename $(sources))

```

```
all: $(targets)
clean:
    rm -f $(targets) $(objects) *.core
```

24.1.6. Licensing the Embedded Server

We encourage everyone to promote free software by releasing code under the GPL or a compatible license. For those who are not able to do this, another option is to purchase a commercial license for the MySQL code from MySQL AB. For details, please see <http://www.mysql.com/company/legal/licensing/>.

24.2. MySQL C API

The C API code is distributed with MySQL. It is included in the `mysqlclient` library and allows C programs to access a database.

Many of the clients in the MySQL source distribution are written in C. If you are looking for examples that demonstrate how to use the C API, take a look at these clients. You can find these in the `clients` directory in the MySQL source distribution.

Most of the other client APIs (all except Connector/J and Connector/NET) use the `mysqlclient` library to communicate with the MySQL server. This means that, for example, you can take advantage of many of the same environment variables that are used by other client programs, because they are referenced from the library. See [Chapter 8, Client and Utility Programs](#), for a list of these variables.

The client has a maximum communication buffer size. The size of the buffer that is allocated initially (16KB) is automatically increased up to the maximum size (the maximum is 16MB). Because buffer sizes are increased only as demand warrants, simply increasing the default maximum limit does not in itself cause more resources to be used. This size check is mostly a check for erroneous statements and communication packets.

The communication buffer must be large enough to contain a single SQL statement (for client-to-server traffic) and one row of returned data (for server-to-client traffic). Each thread's communication buffer is dynamically enlarged to handle any query or row up to the maximum limit. For example, if you have `BLOB` values that contain up to 16MB of data, you must have a communication buffer limit of at least 16MB (in both server and client). The client's default maximum is 16MB, but the default maximum in the server is 1MB. You can increase this by changing the value of the `max_allowed_packet` parameter when the server is started. See [Section 7.5.2, "Tuning Server Parameters"](#).

The MySQL server shrinks each communication buffer to `net_buffer_length` bytes after each query. For clients, the size of the buffer associated with a connection is not decreased until the connection is closed, at which time client memory is reclaimed.

For programming with threads, see [Section 24.2.15, "How to Make a Threaded Client"](#). For creating a standalone application which includes the "server" and "client" in the same program (and does not communicate with an external MySQL server), see [Section 24.1, "libmysqld, the Embedded MySQL Server Library"](#).

24.2.1. C API Data types

- `MYSQL`

This structure represents a handle to one database connection. It is used for almost all MySQL functions. You should not try to make a copy of a `MYSQL` structure. There is no guarantee that such a

copy will be usable.

- `MYSQL_RES`

This structure represents the result of a query that returns rows (`SELECT`, `SHOW`, `DESCRIBE`, `EXPLAIN`). The information returned from a query is called the *result set* in the remainder of this section.

- `MYSQL_ROW`

This is a type-safe representation of one row of data. It is currently implemented as an array of counted byte strings. (You cannot treat these as null-terminated strings if field values may contain binary data, because such values may contain null bytes internally.) Rows are obtained by calling `mysql_fetch_row()`.

- `MYSQL_FIELD`

This structure contains information about a field, such as the field's name, type, and size. Its members are described in more detail here. You may obtain the `MYSQL_FIELD` structures for each field by calling `mysql_fetch_field()` repeatedly. Field values are not part of this structure; they are contained in a `MYSQL_ROW` structure.

- `MYSQL_FIELD_OFFSET`

This is a type-safe representation of an offset into a MySQL field list. (Used by `mysql_field_seek()`.) Offsets are field numbers within a row, beginning at zero.

- `my_ulonglong`

The type used for the number of rows and for `mysql_affected_rows()`, `mysql_num_rows()`, and `mysql_insert_id()`. This type provides a range of 0 to 1.84e19.

On some systems, attempting to print a value of type `my_ulonglong` does not work. To print such a value, convert it to `unsigned long` and use a `%lu` print format. Example:

```
printf ("Number of rows: %lu\n",
        (unsigned long) mysql_num_rows(result));
```

- `my_bool`

A boolean type, for values that are true (non-zero) or false (zero).

The `MYSQL_FIELD` structure contains the members listed here:

- `char * name`

The name of the field, as a null-terminated string. If the field was given an alias with an `AS` clause, the value of `name` is the alias.

- `char * org_name`

The name of the field, as a null-terminated string. Aliases are ignored.

- `char * table`

The name of the table containing this field, if it isn't a calculated field. For calculated fields, the `ta-`

`table` value is an empty string. If the table was given an alias with an `AS` clause, the value of `table` is the alias.

- `char * org_table`

The name of the table, as a null-terminated string. Aliases are ignored.

- `char * db`

The name of the database that the field comes from, as a null-terminated string. If the field is a calculated field, `db` is an empty string.

- `char * catalog`

The catalog name. This value is always "def".

- `char * def`

The default value of this field, as a null-terminated string. This is set only if you use `mysql_list_fields()`.

- `unsigned long length`

The width of the field, as specified in the table definition.

- `unsigned long max_length`

The maximum width of the field for the result set (the length of the longest field value for the rows actually in the result set). If you use `mysql_store_result()` or `mysql_list_fields()`, this contains the maximum length for the field. If you use `mysql_use_result()`, the value of this variable is zero.

- `unsigned int name_length`

The length of `name`.

- `unsigned int org_name_length`

The length of `org_name`.

- `unsigned int table_length`

The length of `table`.

- `unsigned int org_table_length`

The length of `org_table`.

- `unsigned int db_length`

The length of `db`.

- `unsigned int catalog_length`

The length of `catalog`.

- `unsigned int def_length`

The length of `def`.

- `unsigned int flags`

Different bit-flags for the field. The `flags` value may have zero or more of the following bits set:

Flag Value	Flag Description
<code>NOT_NULL_FLAG</code>	Field can't be <code>NULL</code>
<code>PRI_KEY_FLAG</code>	Field is part of a primary key
<code>UNIQUE_KEY_FLAG</code>	Field is part of a unique key
<code>MULTIPLE_KEY_FLAG</code>	Field is part of a non-unique key
<code>UNSIGNED_FLAG</code>	Field has the <code>UNSIGNED</code> attribute
<code>ZEROFILL_FLAG</code>	Field has the <code>ZEROFILL</code> attribute
<code>BINARY_FLAG</code>	Field has the <code>BINARY</code> attribute
<code>AUTO_INCREMENT_FLAG</code>	Field has the <code>AUTO_INCREMENT</code> attribute
<code>ENUM_FLAG</code>	Field is an <code>ENUM</code> (deprecated)
<code>SET_FLAG</code>	Field is a <code>SET</code> (deprecated)
<code>BLOB_FLAG</code>	Field is a <code>BLOB</code> or <code>TEXT</code> (deprecated)
<code>TIMESTAMP_FLAG</code>	Field is a <code>TIMESTAMP</code> (deprecated)

Use of the `BLOB_FLAG`, `ENUM_FLAG`, `SET_FLAG`, and `TIMESTAMP_FLAG` flags is deprecated because they indicate the type of a field rather than an attribute of its type. It is preferable to test `field->type` against `MYSQL_TYPE_BLOB`, `MYSQL_TYPE_ENUM`, `MYSQL_TYPE_SET`, or `MYSQL_TYPE_TIMESTAMP` instead.

The following example illustrates a typical use of the `flags` value:

```
if (field->flags & NOT_NULL_FLAG)
    printf("Field can't be null\n");
```

You may use the following convenience macros to determine the boolean status of the `flags` value:

Flag Status	Description
<code>IS_NOT_NULL(flags)</code>	True if this field is defined as <code>NOT NULL</code>
<code>IS_PRI_KEY(flags)</code>	True if this field is a primary key
<code>IS_BLOB(flags)</code>	True if this field is a <code>BLOB</code> or <code>TEXT</code> (deprecated; test <code>field->type</code> instead)

- `unsigned int decimals`

The number of decimals for numeric fields.

- `unsigned int charsetnr`

The character set number for the field.

- `enum enum_field_types type`

The type of the field. The `type` value may be one of the `MYSQL_TYPE_` symbols shown in the following table.

Type Value	Type Description
------------	------------------

<code>MYSQL_TYPE_TINY</code>	TINYINT field
<code>MYSQL_TYPE_SHORT</code>	SMALLINT field
<code>MYSQL_TYPE_LONG</code>	INTEGER field
<code>MYSQL_TYPE_INT24</code>	MEDIUMINT field
<code>MYSQL_TYPE_LONGLONG</code>	BIGINT field
<code>MYSQL_TYPE_DECIMAL</code>	DECIMAL or NUMERIC field
<code>MYSQL_TYPE_NEWDECIMAL</code>	Precision math DECIMAL or NUMERIC
<code>MYSQL_TYPE_FLOAT</code>	FLOAT field
<code>MYSQL_TYPE_DOUBLE</code>	DOUBLE or REAL field
<code>MYSQL_TYPE_BIT</code>	BIT field
<code>MYSQL_TYPE_TIMESTAMP</code>	TIMESTAMP field
<code>MYSQL_TYPE_DATE</code>	DATE field
<code>MYSQL_TYPE_TIME</code>	TIME field
<code>MYSQL_TYPE_DATETIME</code>	DATETIME field
<code>MYSQL_TYPE_YEAR</code>	YEAR field
<code>MYSQL_TYPE_STRING</code>	CHAR or BINARY field
<code>MYSQL_TYPE_VAR_STRING</code>	VARCHAR or VARBINARY field
<code>MYSQL_TYPE_BLOB</code>	BLOB or TEXT field (use <code>max_length</code> to determine the maximum length)
<code>MYSQL_TYPE_SET</code>	SET field
<code>MYSQL_TYPE_ENUM</code>	ENUM field
<code>MYSQL_TYPE_GEOMETRY</code>	Spatial field
<code>MYSQL_TYPE_NULL</code>	NULL-type field
<code>MYSQL_TYPE_CHAR</code>	Deprecated; use <code>MYSQL_TYPE_TINY</code> instead

You can use the `IS_NUM()` macro to test whether a field has a numeric type. Pass the `type` value to `IS_NUM()` and it evaluates to TRUE if the field is numeric:

```
if (IS_NUM(field->type))
    printf("Field is numeric\n");
```

To distinguish between binary and non-binary data for string data types, check whether the `charsetnr` value is 63. If so, the character set is `binary`, which indicates binary rather than non-binary data. This is how to distinguish between `BINARY` and `CHAR`, `VARBINARY` and `VARCHAR`, and `BLOB` and `TEXT`.

24.2.2. C API Function Overview

The functions available in the C API are summarized here and described in greater detail in a later section. See [Section 24.2.3, “C API Function Descriptions”](#).

Function	Description
<code>mysql_affected_rows()</code>	Returns the number of rows changed/deleted/inserted by the last <code>UPDATE</code> , <code>DELETE</code> , or <code>INSERT</code> query.
<code>mysql_autocommit()</code>	Toggles autocommit mode on/off.

mysql_change_user()	Changes user and database on an open connection.
mysql_close()	Closes a server connection.
mysql_commit()	Commits the transaction.
mysql_connect()	Connects to a MySQL server. This function is deprecated; use mysql_real_connect() instead.
mysql_create_db()	Creates a database. This function is deprecated; use the SQL statement <code>CREATE DATABASE</code> instead.
mysql_data_seek()	Seeks to an arbitrary row number in a query result set.
mysql_debug()	Does a <code>DEBUG_PUSH</code> with the given string.
mysql_drop_db()	Drops a database. This function is deprecated; use the SQL statement <code>DROP DATABASE</code> instead.
mysql_dump_debug_info()	Makes the server write debug information to the log.
mysql_eof()	Determines whether the last row of a result set has been read. This function is deprecated; mysql_errno() or mysql_error() may be used instead.
mysql_errno()	Returns the error number for the most recently invoked MySQL function.
mysql_error()	Returns the error message for the most recently invoked MySQL function.
mysql_escape_string()	Escapes special characters in a string for use in an SQL statement.
mysql_fetch_field()	Returns the type of the next table field.
mysql_fetch_field_direct()	Returns the type of a table field, given a field number.
mysql_fetch_fields()	Returns an array of all field structures.
mysql_fetch_lengths()	Returns the lengths of all columns in the current row.
mysql_fetch_row()	Fetches the next row from the result set.
mysql_field_seek()	Puts the column cursor on a specified column.
mysql_field_count()	Returns the number of result columns for the most recent statement.
mysql_field_tell()	Returns the position of the field cursor used for the last mysql_fetch_field() .
mysql_free_result()	Frees memory used by a result set.
mysql_get_client_info()	Returns client version information as a string.
mysql_get_client_version()	Returns client version information as an integer.
mysql_get_host_info()	Returns a string describing the connection.
mysql_get_server_version()	Returns version number of server as an integer.
mysql_get_proto_info()	Returns the protocol version used by the connection.
mysql_get_server_info()	Returns the server version number.
mysql_info()	Returns information about the most recently executed query.
mysql_init()	Gets or initializes a <code>MYSQL</code> structure.
mysql_insert_id()	Returns the ID generated for an <code>AUTO_INCREMENT</code> column by the previous query.
mysql_kill()	Kills a given thread.
mysql_library_end()	Finalize MySQL C API library.
mysql_library_init()	Initialize MySQL C API library.
mysql_list_dbs()	Returns database names matching a simple regular expression.

<code>mysql_list_fields()</code>	Returns field names matching a simple regular expression.
<code>mysql_list_processes()</code>	Returns a list of the current server threads.
<code>mysql_list_tables()</code>	Returns table names matching a simple regular expression.
<code>mysql_more_results()</code>	Checks whether any more results exist.
<code>mysql_next_result()</code>	Returns/initiates the next result in multiple-statement executions.
<code>mysql_num_fields()</code>	Returns the number of columns in a result set.
<code>mysql_num_rows()</code>	Returns the number of rows in a result set.
<code>mysql_options()</code>	Sets connect options for <code>mysql_connect()</code> .
<code>mysql_ping()</code>	Checks whether the connection to the server is working, reconnecting as necessary.
<code>mysql_query()</code>	Executes an SQL query specified as a null-terminated string.
<code>mysql_real_connect()</code>	Connects to a MySQL server.
<code>mysql_real_escape_string()</code>	Escapes special characters in a string for use in an SQL statement, taking into account the current character set of the connection.
<code>mysql_real_query()</code>	Executes an SQL query specified as a counted string.
<code>mysql_refresh()</code>	Flush or reset tables and caches.
<code>mysql_reload()</code>	Tells the server to reload the grant tables.
<code>mysql_rollback()</code>	Rolls back the transaction.
<code>mysql_row_seek()</code>	Seeks to a row offset in a result set, using value returned from <code>mysql_row_tell()</code> .
<code>mysql_row_tell()</code>	Returns the row cursor position.
<code>mysql_select_db()</code>	Selects a database.
<code>mysql_server_end()</code>	Finalize embedded server library.
<code>mysql_server_init()</code>	Initialize embedded server library.
<code>mysql_set_local_infile_default()</code>	Set the <code>LOAD DATA LOCAL INFILE</code> handler callbacks to their default values.
<code>mysql_set_local_infile_handler()</code>	Install application-specific <code>LOAD DATA LOCAL INFILE</code> handler callbacks.
<code>mysql_set_server_option()</code>	Sets an option for the connection (like <code>multi-statements</code>).
<code>mysql_sqlstate()</code>	Returns the SQLSTATE error code for the last error.
<code>mysql_shutdown()</code>	Shuts down the database server.
<code>mysql_stat()</code>	Returns the server status as a string.
<code>mysql_store_result()</code>	Retrieves a complete result set to the client.
<code>mysql_thread_id()</code>	Returns the current thread ID.
<code>mysql_thread_safe()</code>	Returns 1 if the clients are compiled as thread-safe.
<code>mysql_use_result()</code>	Initiates a row-by-row result set retrieval.
<code>mysql_warning_count()</code>	Returns the warning count for the previous SQL statement.

Application programs should use this general outline for interacting with MySQL:

1. Initialize the MySQL library by calling `mysql_library_init()`. The library can be either the `mysqlclient` C client library or the `mysqld` embedded server library, depending on whether the application was linked with the `-libmysqlclient` or `-libmysqld` flag.

2. Initialize a connection handler by calling `mysql_init()` and connect to the server by calling `mysql_real_connect()`.
3. Issue SQL statements and process their results. (The following discussion provides more information about how to do this.)
4. Close the connection to the MySQL server by calling `mysql_close()`.
5. End use of the MySQL library by calling `mysql_library_end()`.

The purpose of calling `mysql_library_init()` and `mysql_library_end()` is to provide proper initialization and finalization of the MySQL library. For applications that are linked with the client library, they provide improved memory management. If you don't call `mysql_library_end()`, a block of memory remains allocated. (This does not increase the amount of memory used by the application, but some memory leak detectors will complain about it.) For applications that are linked with the embedded server, these calls start and stop the server.

`mysql_library_init()` and `mysql_library_end()` are actually `#define` symbols that make them equivalent to `mysql_server_init()` and `mysql_server_end()`, but the names more clearly indicate that they should be called when beginning and ending use of a MySQL library no matter whether the application uses the `mysqlclient` or `mysqld` library. For older versions of MySQL, you can call `mysql_server_init()` and `mysql_server_end()` instead.

In a non-multi-threaded environment, the call to `mysql_library_init()` may be omitted, because `mysql_init()` will invoke it automatically as necessary. However, a race condition is possible if `mysql_library_init()` is invoked by `mysql_init()` in a multi-threaded environment: `mysql_library_init()` is not thread-safe, so it should be called prior to any other client library call.

To connect to the server, call `mysql_init()` to initialize a connection handler, then call `mysql_real_connect()` with that handler (along with other information such as the hostname, username, and password). Upon connection, `mysql_real_connect()` sets the `reconnect` flag (part of the `MYSQL` structure) to a value of `1` in versions of the API older than 5.0.3, or `0` in newer versions. A value of `1` for this flag indicates that if a statement cannot be performed because of a lost connection, to try reconnecting to the server before giving up. As of MySQL 5.0.13, you can use the `MYSQL_OPT_RECONNECT` option to `mysql_options()` to control reconnection behavior. When you are done with the connection, call `mysql_close()` to terminate it.

While a connection is active, the client may send SQL statements to the server using `mysql_query()` or `mysql_real_query()`. The difference between the two is that `mysql_query()` expects the query to be specified as a null-terminated string whereas `mysql_real_query()` expects a counted string. If the string contains binary data (which may include null bytes), you must use `mysql_real_query()`.

For each non-`SELECT` query (for example, `INSERT`, `UPDATE`, `DELETE`), you can find out how many rows were changed (affected) by calling `mysql_affected_rows()`.

For `SELECT` queries, you retrieve the selected rows as a result set. (Note that some statements are `SELECT`-like in that they return rows. These include `SHOW`, `DESCRIBE`, and `EXPLAIN`. They should be treated the same way as `SELECT` statements.)

There are two ways for a client to process result sets. One way is to retrieve the entire result set all at once by calling `mysql_store_result()`. This function acquires from the server all the rows returned by the query and stores them in the client. The second way is for the client to initiate a row-by-row result set retrieval by calling `mysql_use_result()`. This function initializes the retrieval, but does not actually get any rows from the server.

In both cases, you access rows by calling `mysql_fetch_row()`. With `mysql_store_result()`,

`mysql_fetch_row()` accesses rows that have previously been fetched from the server. With `mysql_use_result()`, `mysql_fetch_row()` actually retrieves the row from the server. Information about the size of the data in each row is available by calling `mysql_fetch_lengths()`.

After you are done with a result set, call `mysql_free_result()` to free the memory used for it.

The two retrieval mechanisms are complementary. Client programs should choose the approach that is most appropriate for their requirements. In practice, clients tend to use `mysql_store_result()` more commonly.

An advantage of `mysql_store_result()` is that because the rows have all been fetched to the client, you not only can access rows sequentially, you can move back and forth in the result set using `mysql_data_seek()` or `mysql_row_seek()` to change the current row position within the result set. You can also find out how many rows there are by calling `mysql_num_rows()`. On the other hand, the memory requirements for `mysql_store_result()` may be very high for large result sets and you are more likely to encounter out-of-memory conditions.

An advantage of `mysql_use_result()` is that the client requires less memory for the result set because it maintains only one row at a time (and because there is less allocation overhead, `mysql_use_result()` can be faster). Disadvantages are that you must process each row quickly to avoid tying up the server, you don't have random access to rows within the result set (you can only access rows sequentially), and you don't know how many rows are in the result set until you have retrieved them all. Furthermore, you **must** retrieve all the rows even if you determine in mid-retrieval that you've found the information you were looking for.

The API makes it possible for clients to respond appropriately to statements (retrieving rows only as necessary) without knowing whether the statement is a `SELECT`. You can do this by calling `mysql_store_result()` after each `mysql_query()` (or `mysql_real_query()`). If the result set call succeeds, the statement was a `SELECT` and you can read the rows. If the result set call fails, call `mysql_field_count()` to determine whether a result was actually to be expected. If `mysql_field_count()` returns zero, the statement returned no data (indicating that it was an `INSERT`, `UPDATE`, `DELETE`, and so forth), and was not expected to return rows. If `mysql_field_count()` is non-zero, the statement should have returned rows, but didn't. This indicates that the statement was a `SELECT` that failed. See the description for `mysql_field_count()` for an example of how this can be done.

Both `mysql_store_result()` and `mysql_use_result()` allow you to obtain information about the fields that make up the result set (the number of fields, their names and types, and so forth). You can access field information sequentially within the row by calling `mysql_fetch_field()` repeatedly, or by field number within the row by calling `mysql_fetch_field_direct()`. The current field cursor position may be changed by calling `mysql_field_seek()`. Setting the field cursor affects subsequent calls to `mysql_fetch_field()`. You can also get information for fields all at once by calling `mysql_fetch_fields()`.

For detecting and reporting errors, MySQL provides access to error information by means of the `mysql_errno()` and `mysql_error()` functions. These return the error code or error message for the most recently invoked function that can succeed or fail, allowing you to determine when an error occurred and what it was.

24.2.3. C API Function Descriptions

In the descriptions here, a parameter or return value of `NULL` means `NULL` in the sense of the C programming language, not a MySQL `NULL` value.

Functions that return a value generally return a pointer or an integer. Unless specified otherwise, functions returning a pointer return a non-`NULL` value to indicate success or a `NULL` value to indicate an error, and functions returning an integer return zero to indicate success or non-zero to indicate an error. Note that “non-zero” means just that. Unless the function description says otherwise, do not test against a value other than zero:

```

if (result)                /* correct */
    ... error ...

if (result < 0)            /* incorrect */
    ... error ...

if (result == -1)         /* incorrect */
    ... error ...

```

When a function returns an error, the **Errors** subsection of the function description lists the possible types of errors. You can find out which of these occurred by calling `mysql_errno()`. A string representation of the error may be obtained by calling `mysql_error()`.

24.2.3.1. `mysql_affected_rows()`

```
my_ulonglong mysql_affected_rows(MYSQL *mysql)
```

Description

Returns the number of rows changed by the last `UPDATE`, deleted by the last `DELETE` or inserted by the last `INSERT` statement. May be called immediately after `mysql_query()` for `UPDATE`, `DELETE`, or `INSERT` statements. For `SELECT` statements, `mysql_affected_rows()` works like `mysql_num_rows()`.

Return Values

An integer greater than zero indicates the number of rows affected or retrieved. Zero indicates that no records were updated for an `UPDATE` statement, no rows matched the `WHERE` clause in the query or that no query has yet been executed. -1 indicates that the query returned an error or that, for a `SELECT` query, `mysql_affected_rows()` was called prior to calling `mysql_store_result()`. Because `mysql_affected_rows()` returns an unsigned value, you can check for -1 by comparing the return value to `(my_ulonglong)-1` (or to `(my_ulonglong)~0`, which is equivalent).

Errors

None.

Example

```
mysql_query(&mysql,"UPDATE products SET cost=cost*1.25 WHERE group=10");
printf("%ld products updated",(long) mysql_affected_rows(&mysql));
```

If you specify the flag `CLIENT_FOUND_ROWS` when connecting to `mysqld`, `mysql_affected_rows()` returns the number of rows matched by the `WHERE` statement for `UPDATE` statements. Otherwise, it returns the number of rows actually changed.

Note that when you use a `REPLACE` command, `mysql_affected_rows()` returns 2 if the new row replaced an old row, because in this case, one row was inserted after the duplicate was deleted.

If you use `INSERT ... ON DUPLICATE KEY UPDATE` to insert a row, `mysql_affected_rows()` returns 1 if the row is inserted as a new row and 2 if an existing row is updated.

24.2.3.2. `mysql_autocommit()`

```
my_bool mysql_autocommit(MYSQL *mysql, my_bool mode)
```

Description

Sets autocommit mode on if `mode` is 1, off if `mode` is 0.

Return Values

Zero if successful. Non-zero if an error occurred.

Errors

None.

24.2.3.3. `mysql_change_user()`

```
my_bool mysql_change_user(MYSQL *mysql, const char *user, const char
*password, const char *db)
```

Description

Changes the user and causes the database specified by `db` to become the default (current) database on the connection specified by `mysql`. In subsequent queries, this database is the default for table references that do not include an explicit database specifier.

`mysql_change_user()` fails if the connected user cannot be authenticated or doesn't have permission to use the database. In this case, the user and database are not changed.

The `db` parameter may be set to `NULL` if you don't want to have a default database.

This command always performs a `ROLLBACK` of any active transactions, closes all temporary tables, unlocks all locked tables and resets the state as if one had done a new connect. This happens even if the user didn't change.

Return Values

Zero for success. Non-zero if an error occurred.

Errors

The same that you can get from `mysql_real_connect()`.

- `CR_COMMANDS_OUT_OF_SYNC`
Commands were executed in an improper order.
- `CR_SERVER_GONE_ERROR`
The MySQL server has gone away.
- `CR_SERVER_LOST`
The connection to the server was lost during the query.
- `CR_UNKNOWN_ERROR`
An unknown error occurred.
- `ER_UNKNOWN_COM_ERROR`
The MySQL server doesn't implement this command (probably an old server).
- `ER_ACCESS_DENIED_ERROR`

The user or password was wrong.

- `ER_BAD_DB_ERROR`

The database didn't exist.

- `ER_DBACCESS_DENIED_ERROR`

The user did not have access rights to the database.

- `ER_WRONG_DB_NAME`

The database name was too long.

Example

```
if (mysql_change_user(&mysql, "user", "password", "new_database"))
{
    fprintf(stderr, "Failed to change user. Error: %s\n",
            mysql_error(&mysql));
}
```

24.2.3.4. `mysql_character_set_name()`

```
const char *mysql_character_set_name(MYSQL *mysql)
```

Description

Returns the default character set for the current connection.

Return Values

The default character set

Errors

None.

24.2.3.5. `mysql_close()`

```
void mysql_close(MYSQL *mysql)
```

Description

Closes a previously opened connection. `mysql_close()` also deallocates the connection handle pointed to by `mysql` if the handle was allocated automatically by `mysql_init()` or `mysql_connect()`.

Return Values

None.

Errors

None.

24.2.3.6. `mysql_commit()`

```
my_bool mysql_commit(MYSQL *mysql)
```

Description

Commits the current transaction.

The action of this function is subject to the value of the `completion_type` system variable. In particular, if the value of `completion_type` is 2, the server performs a release after terminating a transaction and closes the client connection. The client program should call `mysql_close()` to close the connection from the client side.

Return Values

Zero if successful. Non-zero if an error occurred.

Errors

None.

24.2.3.7. `mysql_connect()`

```
MYSQL *mysql_connect(MYSQL *mysql, const char *host, const char *user,  
const char *passwd)
```

Description

This function is deprecated. It is preferable to use `mysql_real_connect()` instead.

`mysql_connect()` attempts to establish a connection to a MySQL database engine running on `host`. `mysql_connect()` must complete successfully before you can execute any of the other API functions, with the exception of `mysql_get_client_info()`.

The meanings of the parameters are the same as for the corresponding parameters for `mysql_real_connect()` with the difference that the connection parameter may be `NULL`. In this case, the C API allocates memory for the connection structure automatically and frees it when you call `mysql_close()`. The disadvantage of this approach is that you can't retrieve an error message if the connection fails. (To get error information from `mysql_errno()` or `mysql_error()`, you must provide a valid `MYSQL` pointer.)

Return Values

Same as for `mysql_real_connect()`.

Errors

Same as for `mysql_real_connect()`.

24.2.3.8. `mysql_create_db()`

```
int mysql_create_db(MYSQL *mysql, const char *db)
```

Description

Creates the database named by the `db` parameter.

This function is deprecated. It is preferable to use `mysql_query()` to issue an SQL `CREATE DATABASE` statement instead.

Return Values

Zero if the database was created successfully. Non-zero if an error occurred.

Errors

- `CR_COMMANDS_OUT_OF_SYNC`
Commands were executed in an improper order.
- `CR_SERVER_GONE_ERROR`
The MySQL server has gone away.
- `CR_SERVER_LOST`
The connection to the server was lost during the query.
- `CR_UNKNOWN_ERROR`
An unknown error occurred.

Example

```
if(mysql_create_db(&mysql, "my_database"))
{
    fprintf(stderr, "Failed to create new database. Error: %s\n",
            mysql_error(&mysql));
}
```

24.2.3.9. `mysql_data_seek()`

```
void mysql_data_seek(MYSQL_RES *result, my_ulonglong offset)
```

Description

Seeks to an arbitrary row in a query result set. The `offset` value is a row number and should be in the range from 0 to `mysql_num_rows(result)-1`.

This function requires that the result set structure contains the entire result of the query, so `mysql_data_seek()` may be used only in conjunction with `mysql_store_result()`, not with `mysql_use_result()`.

Return Values

None.

Errors

None.

24.2.3.10. `mysql_debug()`

```
void mysql_debug(const char *debug)
```

Description

Does a `DBUG_PUSH` with the given string. `mysql_debug()` uses the Fred Fish debug library. To use this function, you must compile the client library to support debugging. See [Section E.1, “Debugging a MySQL Server”](#), and [Section E.2, “Debugging a MySQL Client”](#).

Return Values

None.

Errors

None.

Example

The call shown here causes the client library to generate a trace file in `/tmp/client.trace` on the client machine:

```
mysql_debug("d:t:O,/tmp/client.trace");
```

24.2.3.11. `mysql_drop_db()`

```
int mysql_drop_db(MYSQL *mysql, const char *db)
```

Description

Drops the database named by the `db` parameter.

This function is deprecated. It is preferable to use `mysql_query()` to issue an SQL `DROP DATABASE` statement instead.

Return Values

Zero if the database was dropped successfully. Non-zero if an error occurred.

Errors

- `CR_COMMANDS_OUT_OF_SYNC`
Commands were executed in an improper order.
- `CR_SERVER_GONE_ERROR`
The MySQL server has gone away.
- `CR_SERVER_LOST`
The connection to the server was lost during the query.
- `CR_UNKNOWN_ERROR`
An unknown error occurred.

Example

```
if(mysql_drop_db(&mysql, "my_database"))  
    fprintf(stderr, "Failed to drop the database: Error: %s\n",  
            mysql_error(&mysql));
```

24.2.3.12. `mysql_dump_debug_info()`

```
int mysql_dump_debug_info(MYSQL *mysql)
```

Description

Instructs the server to write some debug information to the log. For this to work, the connected user must have the `SUPER` privilege.

Return Values

Zero if the command was successful. Non-zero if an error occurred.

Errors

- `CR_COMMANDS_OUT_OF_SYNC`
Commands were executed in an improper order.
- `CR_SERVER_GONE_ERROR`
The MySQL server has gone away.
- `CR_SERVER_LOST`
The connection to the server was lost during the query.
- `CR_UNKNOWN_ERROR`
An unknown error occurred.

24.2.3.13. `mysql_eof()`

```
my_bool mysql_eof(MYSQL_RES *result)
```

Description

This function is deprecated. `mysql_errno()` or `mysql_error()` may be used instead.

`mysql_eof()` determines whether the last row of a result set has been read.

If you acquire a result set from a successful call to `mysql_store_result()`, the client receives the entire set in one operation. In this case, a `NULL` return from `mysql_fetch_row()` always means the end of the result set has been reached and it is unnecessary to call `mysql_eof()`. When used with `mysql_store_result()`, `mysql_eof()` always returns true.

On the other hand, if you use `mysql_use_result()` to initiate a result set retrieval, the rows of the set are obtained from the server one by one as you call `mysql_fetch_row()` repeatedly. Because an error may occur on the connection during this process, a `NULL` return value from `mysql_fetch_row()` does not necessarily mean the end of the result set was reached normally. In this case, you can use `mysql_eof()` to determine what happened. `mysql_eof()` returns a non-zero value if the end of the result set was reached and zero if an error occurred.

Historically, `mysql_eof()` predates the standard MySQL error functions `mysql_errno()` and `mysql_error()`. Because those error functions provide the same information, their use is preferred over `mysql_eof()`, which is deprecated. (In fact, they provide more information, because `mysql_eof()` returns only a boolean value whereas the error functions indicate a reason for the error when one occurs.)

Return Values

Zero if no error occurred. Non-zero if the end of the result set has been reached.

Errors

None.

Example

The following example shows how you might use `mysql_eof()`:

```
mysql_query(&mysql, "SELECT * FROM some_table");
result = mysql_use_result(&mysql);
while((row = mysql_fetch_row(result)))
{
    // do something with data
}
if(!mysql_eof(result)) // mysql_fetch_row() failed due to an error
{
    fprintf(stderr, "Error: %s\n", mysql_error(&mysql));
}
```

However, you can achieve the same effect with the standard MySQL error functions:

```
mysql_query(&mysql, "SELECT * FROM some_table");
result = mysql_use_result(&mysql);
while((row = mysql_fetch_row(result)))
{
    // do something with data
}
if(mysql_errno(&mysql)) // mysql_fetch_row() failed due to an error
{
    fprintf(stderr, "Error: %s\n", mysql_error(&mysql));
}
```

24.2.3.14. `mysql_errno()`

```
unsigned int mysql_errno(MYSQL *mysql)
```

Description

For the connection specified by `mysql`, `mysql_errno()` returns the error code for the most recently invoked API function that can succeed or fail. A return value of zero means that no error occurred. Client error message numbers are listed in the MySQL `errmsg.h` header file. Server error message numbers are listed in `mysqld_error.h`. Errors also are listed at [Appendix B, Error Codes and Messages](#).

Note that some functions like `mysql_fetch_row()` don't set `mysql_errno()` if they succeed.

A rule of thumb is that all functions that have to ask the server for information reset `mysql_errno()` if they succeed.

MySQL-specific error numbers returned by `mysql_errno()` differ from SQLSTATE values returned by `mysql_sqlstate()`. For example, the `mysql` client program displays errors using the following format, where 1146 is the `mysql_errno()` value and '42S02' is the corresponding `mysql_sqlstate()` value:

```
shell> SELECT * FROM no_such_table;
ERROR 1146 (42S02): Table 'test.no_such_table' doesn't exist
```

Return Values

An error code value for the last `mysql_xxx()` call, if it failed. zero means no error occurred.

Errors

None.

24.2.3.15. `mysql_error()`

```
const char *mysql_error(MYSQL *mysql)
```

Description

For the connection specified by `mysql`, `mysql_error()` returns a null-terminated string containing the error message for the most recently invoked API function that failed. If a function didn't fail, the return value of `mysql_error()` may be the previous error or an empty string to indicate no error.

A rule of thumb is that all functions that have to ask the server for information reset `mysql_error()` if they succeed.

For functions that reset `mysql_errno()`, the following two tests are equivalent:

```
if(mysql_errno(&mysql))
{
    // an error occurred
}

if(mysql_error(&mysql)[0] != '\0')
{
    // an error occurred
}
```

The language of the client error messages may be changed by recompiling the MySQL client library. Currently, you can choose error messages in several different languages. See [Section 5.11.2, “Setting the Error Message Language”](#).

Return Values

A null-terminated character string that describes the error. An empty string if no error occurred.

Errors

None.

24.2.3.16. `mysql_escape_string()`

You should use `mysql_real_escape_string()` instead!

This function is identical to `mysql_real_escape_string()` except that `mysql_real_escape_string()` takes a connection handler as its first argument and escapes the string according to the current character set. `mysql_escape_string()` does not take a connection argument and does not respect the current character set.

24.2.3.17. `mysql_fetch_field()`

```
MYSQL_FIELD *mysql_fetch_field(MYSQL_RES *result)
```

Description

Returns the definition of one column of a result set as a `MYSQL_FIELD` structure. Call this function repeatedly to retrieve information about all columns in the result set. `mysql_fetch_field()` returns `NULL` when no more fields are left.

`mysql_fetch_field()` is reset to return information about the first field each time you execute a new `SELECT` query. The field returned by `mysql_fetch_field()` is also affected by calls to

`mysql_field_seek()`.

If you've called `mysql_query()` to perform a `SELECT` on a table but have not called `mysql_store_result()`, MySQL returns the default blob length (8KB) if you call `mysql_fetch_field()` to ask for the length of a `BLOB` field. (The 8KB size is chosen because MySQL doesn't know the maximum length for the `BLOB`. This should be made configurable sometime.) Once you've retrieved the result set, `field->max_length` contains the length of the largest value for this column in the specific query.

Return Values

The `MYSQL_FIELD` structure for the current column. `NULL` if no columns are left.

Errors

None.

Example

```
MYSQL_FIELD *field;

while((field = mysql_fetch_field(result)))
{
    printf("field name %s\n", field->name);
}
```

24.2.3.18. `mysql_fetch_field_direct()`

```
MYSQL_FIELD *mysql_fetch_field_direct(MYSQL_RES *result, unsigned int
fieldnr)
```

Description

Given a field number `fieldnr` for a column within a result set, returns that column's field definition as a `MYSQL_FIELD` structure. You may use this function to retrieve the definition for an arbitrary column. The value of `fieldnr` should be in the range from 0 to `mysql_num_fields(result)-1`.

Return Values

The `MYSQL_FIELD` structure for the specified column.

Errors

None.

Example

```
unsigned int num_fields;
unsigned int i;
MYSQL_FIELD *field;

num_fields = mysql_num_fields(result);
for(i = 0; i < num_fields; i++)
{
    field = mysql_fetch_field_direct(result, i);
    printf("Field %u is %s\n", i, field->name);
}
```

24.2.3.19. `mysql_fetch_fields()`

```
MYSQL_FIELD *mysql_fetch_fields(MYSQL_RES *result)
```

Description

Returns an array of all `MYSQL_FIELD` structures for a result set. Each structure provides the field definition for one column of the result set.

Return Values

An array of `MYSQL_FIELD` structures for all columns of a result set.

Errors

None.

Example

```
unsigned int num_fields;
unsigned int i;
MYSQL_FIELD *fields;

num_fields = mysql_num_fields(result);
fields = mysql_fetch_fields(result);
for(i = 0; i < num_fields; i++)
{
    printf("Field %u is %s\n", i, fields[i].name);
}
```

24.2.3.20. `mysql_fetch_lengths()`

```
unsigned long *mysql_fetch_lengths(MYSQL_RES *result)
```

Description

Returns the lengths of the columns of the current row within a result set. If you plan to copy field values, this length information is also useful for optimization, because you can avoid calling `strlen()`. In addition, if the result set contains binary data, you **must** use this function to determine the size of the data, because `strlen()` returns incorrect results for any field containing null characters.

The length for empty columns and for columns containing `NULL` values is zero. To see how to distinguish these two cases, see the description for `mysql_fetch_row()`.

Return Values

An array of unsigned long integers representing the size of each column (not including any terminating null characters). `NULL` if an error occurred.

Errors

`mysql_fetch_lengths()` is valid only for the current row of the result set. It returns `NULL` if you call it before calling `mysql_fetch_row()` or after retrieving all rows in the result.

Example

```
MYSQL_ROW row;
unsigned long *lengths;
unsigned int num_fields;
unsigned int i;

row = mysql_fetch_row(result);
if (row)
{
    num_fields = mysql_num_fields(result);
    lengths = mysql_fetch_lengths(result);
    for(i = 0; i < num_fields; i++)
    {
        printf("Column %u is %lu bytes in length.\n",
```

```
        i, lengths[i]);  
    }  
}
```

24.2.3.21. `mysql_fetch_row()`

```
MYSQL_ROW mysql_fetch_row(MYSQL_RES *result)
```

Description

Retrieves the next row of a result set. When used after `mysql_store_result()`, `mysql_fetch_row()` returns `NULL` when there are no more rows to retrieve. When used after `mysql_use_result()`, `mysql_fetch_row()` returns `NULL` when there are no more rows to retrieve or if an error occurred.

The number of values in the row is given by `mysql_num_fields(result)`. If `row` holds the return value from a call to `mysql_fetch_row()`, pointers to the values are accessed as `row[0]` to `row[mysql_num_fields(result)-1]`. `NULL` values in the row are indicated by `NULL` pointers.

The lengths of the field values in the row may be obtained by calling `mysql_fetch_lengths()`. Empty fields and fields containing `NULL` both have length 0; you can distinguish these by checking the pointer for the field value. If the pointer is `NULL`, the field is `NULL`; otherwise, the field is empty.

Return Values

A `MYSQL_ROW` structure for the next row. `NULL` if there are no more rows to retrieve or if an error occurred.

Errors

Note that error is not reset between calls to `mysql_fetch_row()`

- `CR_SERVER_LOST`

The connection to the server was lost during the query.

- `CR_UNKNOWN_ERROR`

An unknown error occurred.

Example

```
MYSQL_ROW row;  
unsigned int num_fields;  
unsigned int i;  
  
num_fields = mysql_num_fields(result);  
while ((row = mysql_fetch_row(result)))  
{  
    unsigned long *lengths;  
    lengths = mysql_fetch_lengths(result);  
    for(i = 0; i < num_fields; i++)  
    {  
        printf("[%s] ", (int) lengths[i],  
              row[i] ? row[i] : "NULL");  
    }  
    printf("\n");  
}
```

24.2.3.22. `mysql_field_count()`

```
unsigned int mysql_field_count(MYSQL *mysql)
```

Description

Returns the number of columns for the most recent query on the connection.

The normal use of this function is when `mysql_store_result()` returned `NULL` (and thus you have no result set pointer). In this case, you can call `mysql_field_count()` to determine whether `mysql_store_result()` should have produced a non-empty result. This allows the client program to take proper action without knowing whether the query was a `SELECT` (or `SELECT`-like) statement. The example shown here illustrates how this may be done.

See [Section 24.2.13.1, “Why `mysql_store_result\(\)` Sometimes Returns `NULL` After `mysql_query\(\)` Returns Success”](#).

Return Values

An unsigned integer representing the number of columns in a result set.

Errors

None.

Example

```
MYSQL_RES *result;
unsigned int num_fields;
unsigned int num_rows;

if (mysql_query(&mysql, query_string))
{
    // error
}
else // query succeeded, process any data returned by it
{
    result = mysql_store_result(&mysql);
    if (result) // there are rows
    {
        num_fields = mysql_num_fields(result);
        // retrieve rows, then call mysql_free_result(result)
    }
    else // mysql_store_result() returned nothing; should it have?
    {
        if(mysql_field_count(&mysql) == 0)
        {
            // query does not return data
            // (it was not a SELECT)
            num_rows = mysql_affected_rows(&mysql);
        }
        else // mysql_store_result() should have returned data
        {
            fprintf(stderr, "Error: %s\n", mysql_error(&mysql));
        }
    }
}
```

An alternative is to replace the `mysql_field_count(&mysql)` call with `mysql_errno(&mysql)`. In this case, you are checking directly for an error from `mysql_store_result()` rather than inferring from the value of `mysql_field_count()` whether the statement was a `SELECT`.

24.2.3.23. `mysql_field_seek()`

```
MYSQL_FIELD_OFFSET mysql_field_seek(MYSQL_RES *result,
MYSQL_FIELD_OFFSET offset)
```

Description

Sets the field cursor to the given offset. The next call to `mysql_fetch_field()` retrieves the field definition of the column associated with that offset.

To seek to the beginning of a row, pass an `offset` value of zero.

Return Values

The previous value of the field cursor.

Errors

None.

24.2.3.24. `mysql_field_tell()`

```
MYSQL_FIELD_OFFSET mysql_field_tell(MYSQL_RES *result)
```

Description

Returns the position of the field cursor used for the last `mysql_fetch_field()`. This value can be used as an argument to `mysql_field_seek()`.

Return Values

The current offset of the field cursor.

Errors

None.

24.2.3.25. `mysql_free_result()`

```
void mysql_free_result(MYSQL_RES *result)
```

Description

Frees the memory allocated for a result set by `mysql_store_result()`, `mysql_use_result()`, `mysql_list_dbs()`, and so forth. When you are done with a result set, you must free the memory it uses by calling `mysql_free_result()`.

Do not attempt to access a result set after freeing it.

Return Values

None.

Errors

None.

24.2.3.26. `mysql_get_character_set_info()`

```
void mysql_get_character_set_info(MYSQL *mysql, MY_CHARSET_INFO *cs)
```

Description

This function provides information about the default client character set. The default character set may

be changed with the `mysql_set_character_set()` function.

This function was added in MySQL 5.0.10.

Example

```
if (!mysql_set_character_set(&mysql, "utf8"))
{
    MY_CHARSET_INFO cs;
    mysql_get_character_set_info(&mysql, &cs);
    printf("character set information:\n");
    printf("character set name: %s\n", cs.name);
    printf("collation name: %s\n", cs.csname);
    printf("comment: %s\n", cs.comment);
    printf("directory: %s\n", cs.dir);
    printf("multi byte character min. length: %d\n", cs.mbminlen);
    printf("multi byte character max. length: %d\n", cs.mbmaxlen);
}
```

24.2.3.27. `mysql_get_client_info()`

```
const char *mysql_get_client_info(void)
```

Description

Returns a string that represents the client library version.

Return Values

A character string that represents the MySQL client library version.

Errors

None.

24.2.3.28. `mysql_get_client_version()`

```
unsigned long mysql_get_client_version(void)
```

Description

Returns an integer that represents the client library version. The value has the format `XYZZZ` where `X` is the major version, `YY` is the release level, and `ZZ` is the version number within the release level. For example, a value of `40102` represents a client library version of `4.1.2`.

Return Values

An integer that represents the MySQL client library version.

Errors

None.

24.2.3.29. `mysql_get_host_info()`

```
const char *mysql_get_host_info(MYSQL *mysql)
```

Description

Returns a string describing the type of connection in use, including the server hostname.

Return Values

A character string representing the server hostname and the connection type.

Errors

None.

24.2.3.30. `mysql_get_proto_info()`

```
unsigned int mysql_get_proto_info(MYSQL *mysql)
```

Description

Returns the protocol version used by current connection.

Return Values

An unsigned integer representing the protocol version used by the current connection.

Errors

None.

24.2.3.31. `mysql_get_server_info()`

```
const char *mysql_get_server_info(MYSQL *mysql)
```

Description

Returns a string that represents the server version number.

Return Values

A character string that represents the server version number.

Errors

None.

24.2.3.32. `mysql_get_server_version()`

```
unsigned long mysql_get_server_version(MYSQL *mysql)
```

Description

Returns the version number of the server as an integer.

Return Values

A number that represents the MySQL server version in this format:

```
major_version*10000 + minor_version *100 + sub_version
```

For example, 5.1.5 is returned as 50105.

This function is useful in client programs for quickly determining whether some version-specific server capability exists.

Errors

None.

24.2.3.33. `mysql_hex_string()`

```
unsigned long mysql_hex_string(char *to, const char *from, unsigned
long length)
```

Description

This function is used to create a legal SQL string that you can use in an SQL statement. See [Section 9.1.1, “Strings”](#).

The string in `from` is encoded to hexadecimal format, with each character encoded as two hexadecimal digits. The result is placed in `to` and a terminating null byte is appended.

The string pointed to by `from` must be `length` bytes long. You must allocate the `to` buffer to be at least `length*2+1` bytes long. When `mysql_hex_string()` returns, the contents of `to` is a null-terminated string. The return value is the length of the encoded string, not including the terminating null character.

The return value can be placed into an SQL statement using either `0xvalue` or `X'value'` format. However, the return value does not include the `0x` or `X' . . . '`. The caller must supply whichever of those is desired.

Example

```
char query[1000],*end;

end = strmov(query,"INSERT INTO test_table values(");
end = strmov(end,"0x");
end += mysql_hex_string(end,"What's this",11);
end = strmov(end,",0x");
end += mysql_hex_string(end,"binary data: \0\r\n",16);
*end++ = ')';

if (mysql_real_query(&mysql,query,(unsigned int) (end - query)))
{
    fprintf(stderr, "Failed to insert row, Error: %s\n",
            mysql_error(&mysql));
}
```

The `strmov()` function used in the example is included in the `mysqlclient` library and works like `strcpy()` but returns a pointer to the terminating null of the first parameter.

Return Values

The length of the value placed into `to`, not including the terminating null character.

Errors

None.

24.2.3.34. `mysql_info()`

```
const char *mysql_info(MYSQL *mysql)
```

Description

Retrieves a string providing information about the most recently executed query, but only for the statements listed here. For other statements, `mysql_info()` returns `NULL`. The format of the string varies

depending on the type of query, as described here. The numbers are illustrative only; the string contains values appropriate for the query.

- `INSERT INTO ... SELECT ...`
String format: `Records: 100 Duplicates: 0 Warnings: 0`
- `INSERT INTO ... VALUES (...),(...),(...)...`
String format: `Records: 3 Duplicates: 0 Warnings: 0`
- `LOAD DATA INFILE ...`
String format: `Records: 1 Deleted: 0 Skipped: 0 Warnings: 0`
- `ALTER TABLE`
String format: `Records: 3 Duplicates: 0 Warnings: 0`
- `UPDATE`
String format: `Rows matched: 40 Changed: 40 Warnings: 0`

Note that `mysql_info()` returns a non-NULL value for `INSERT ... VALUES` only for the multiple-row form of the statement (that is, only if multiple value lists are specified).

Return Values

A character string representing additional information about the most recently executed query. `NULL` if no information is available for the query.

Errors

None.

24.2.3.35. `mysql_init()`

```
MYSQL *mysql_init(MYSQL *mysql)
```

Description

Allocates or initializes a `MYSQL` object suitable for `mysql_real_connect()`. If `mysql` is a `NULL` pointer, the function allocates, initializes, and returns a new object. Otherwise, the object is initialized and the address of the object is returned. If `mysql_init()` allocates a new object, it is freed when `mysql_close()` is called to close the connection.

Return Values

An initialized `MYSQL*` handle. `NULL` if there was insufficient memory to allocate a new object.

Errors

In case of insufficient memory, `NULL` is returned.

24.2.3.36. `mysql_insert_id()`

```
my_ulonglong mysql_insert_id(MYSQL *mysql)
```

Description

Returns the value generated for an `AUTO_INCREMENT` column by the previous `INSERT` or `UPDATE` statement. Use this function after you have performed an `INSERT` statement into a table that contains an `AUTO_INCREMENT` field.

More precisely, `mysql_insert_id()` is updated under these conditions:

- `INSERT` statements that store a value into an `AUTO_INCREMENT` column. This is true whether the value is automatically generated by storing the special values `NULL` or `0` into the column, or is an explicit non-special value.
- In the case of a multiple-row `INSERT` statement, `mysql_insert_id()` returns the **first** automatically generated `AUTO_INCREMENT` value; if no such value is generated, it returns the last **last** explicit value inserted into the `AUTO_INCREMENT` column.
- `INSERT` statements that generate an `AUTO_INCREMENT` value by inserting `LAST_INSERT_ID(expr)` into any column.
- `INSERT` statements that generate an `AUTO_INCREMENT` value by updating any column to `LAST_INSERT_ID(expr)`.
- The value of `mysql_insert_id()` is not affected by statements such as `SELECT` that return a result set.
- If the previous statement returned an error, the value of `mysql_insert_id()` is undefined.

Note that `mysql_insert_id()` returns `0` if the previous statement does not use an `AUTO_INCREMENT` value. If you need to save the value for later, be sure to call `mysql_insert_id()` immediately after the statement that generates the value.

The value of `mysql_insert_id()` is affected only by statements issued within the current client connection. It is not affected by statements issued by other clients.

See [Section 12.10.3, “Information Functions”](#).

Also note that the value of the SQL `LAST_INSERT_ID()` function always contains the most recently generated `AUTO_INCREMENT` value, and is not reset between statements because the value of that function is maintained in the server. Another difference is that `LAST_INSERT_ID()` is not updated if you set an `AUTO_INCREMENT` column to a specific non-special value.

The reason for the difference between `LAST_INSERT_ID()` and `mysql_insert_id()` is that `LAST_INSERT_ID()` is made easy to use in scripts while `mysql_insert_id()` tries to provide a little more exact information of what happens to the `AUTO_INCREMENT` column.

Return Values

Described in the preceding discussion.

Errors

None.

24.2.3.37. `mysql_kill()`

```
int mysql_kill(MYSQL *mysql, unsigned long pid)
```

Description

Asks the server to kill the thread specified by `pid`.

Return Values

Zero for success. Non-zero if an error occurred.

Errors

- `CR_COMMANDS_OUT_OF_SYNC`
Commands were executed in an improper order.
- `CR_SERVER_GONE_ERROR`
The MySQL server has gone away.
- `CR_SERVER_LOST`
The connection to the server was lost during the query.
- `CR_UNKNOWN_ERROR`
An unknown error occurred.

24.2.3.38. `mysql_library_end()`

```
void mysql_library_end(void)
```

Description

This is a synonym for the `mysql_server_end()` function.

See [Section 24.2.2, “C API Function Overview”](#), for usage information.

24.2.3.39. `mysql_library_init()`

```
int mysql_library_init(int argc, char **argv, char **groups)
```

Description

This is a synonym for the `mysql_server_init()` function. See [Section 24.2.12.1, “`mysql_server_init\(\)`”](#).

See [Section 24.2.2, “C API Function Overview”](#) for usage information.

24.2.3.40. `mysql_list_dbs()`

```
MYSQL_RES *mysql_list_dbs(MYSQL *mysql, const char *wild)
```

Description

Returns a result set consisting of database names on the server that match the simple regular expression specified by the `wild` parameter. `wild` may contain the wildcard characters ‘%’ or ‘_’, or may be a `NULL` pointer to match all databases. Calling `mysql_list_dbs()` is similar to executing the query `SHOW databases [LIKE wild]`.

You must free the result set with `mysql_free_result()`.

Return Values

A `MYSQL_RES` result set for success. `NULL` if an error occurred.

Errors

- `CR_COMMANDS_OUT_OF_SYNC`
Commands were executed in an improper order.
- `CR_OUT_OF_MEMORY`
Out of memory.
- `CR_SERVER_GONE_ERROR`
The MySQL server has gone away.
- `CR_SERVER_LOST`
The connection to the server was lost during the query.
- `CR_UNKNOWN_ERROR`
An unknown error occurred.

24.2.3.41. `mysql_list_fields()`

```
MYSQL_RES *mysql_list_fields(MYSQL *mysql, const char *table, const char *wild)
```

Description

Returns a result set consisting of field names in the given table that match the simple regular expression specified by the `wild` parameter. `wild` may contain the wildcard characters `'%'` or `'_'`, or may be a `NULL` pointer to match all fields. Calling `mysql_list_fields()` is similar to executing the query `SHOW COLUMNS FROM tbl_name [LIKE wild]`.

Note that it's recommended that you use `SHOW COLUMNS FROM tbl_name` instead of `mysql_list_fields()`.

You must free the result set with `mysql_free_result()`.

Return Values

A `MYSQL_RES` result set for success. `NULL` if an error occurred.

Errors

- `CR_COMMANDS_OUT_OF_SYNC`
Commands were executed in an improper order.
- `CR_SERVER_GONE_ERROR`

The MySQL server has gone away.

- `CR_SERVER_LOST`

The connection to the server was lost during the query.

- `CR_UNKNOWN_ERROR`

An unknown error occurred.

24.2.3.42. `mysql_list_processes()`

```
MYSQL_RES *mysql_list_processes(MYSQL *mysql)
```

Description

Returns a result set describing the current server threads. This is the same kind of information as that reported by `mysqladmin processlist` or a `SHOW PROCESSLIST` query.

You must free the result set with `mysql_free_result()`.

Return Values

A `MYSQL_RES` result set for success. `NULL` if an error occurred.

Errors

- `CR_COMMANDS_OUT_OF_SYNC`

Commands were executed in an improper order.

- `CR_SERVER_GONE_ERROR`

The MySQL server has gone away.

- `CR_SERVER_LOST`

The connection to the server was lost during the query.

- `CR_UNKNOWN_ERROR`

An unknown error occurred.

24.2.3.43. `mysql_list_tables()`

```
MYSQL_RES *mysql_list_tables(MYSQL *mysql, const char *wild)
```

Description

Returns a result set consisting of table names in the current database that match the simple regular expression specified by the `wild` parameter. `wild` may contain the wildcard characters `'%'` or `'_'`, or may be a `NULL` pointer to match all tables. Calling `mysql_list_tables()` is similar to executing the query `SHOW tables [LIKE wild]`.

You must free the result set with `mysql_free_result()`.

Return Values

A `MYSQL_RES` result set for success. `NULL` if an error occurred.

Errors

- `CR_COMMANDS_OUT_OF_SYNC`
Commands were executed in an improper order.
- `CR_SERVER_GONE_ERROR`
The MySQL server has gone away.
- `CR_SERVER_LOST`
The connection to the server was lost during the query.
- `CR_UNKNOWN_ERROR`
An unknown error occurred.

24.2.3.44. `mysql_more_results()`

```
my_bool mysql_more_results(MYSQL *mysql)
```

Description

Returns true if more results exist from the currently executed query, and the application must call `mysql_next_result()` to fetch the results.

Return Values

`TRUE` (1) if more results exist. `FALSE` (0) if no more results exist.

In most cases, you can call `mysql_next_result()` instead to test whether more results exist and initiate retrieval if so.

See [Section 24.2.9, “C API Handling of Multiple Statement Execution”](#), and [Section 24.2.3.45, “`mysql_next_result\(\)`”](#).

Errors

None.

24.2.3.45. `mysql_next_result()`

```
int mysql_next_result(MYSQL *mysql)
```

Description

If more query results exist, `mysql_next_result()` reads the next query results and returns the status back to application.

You must call `mysql_free_result()` for the preceding query if it returned a result set.

After calling `mysql_next_result()` the state of the connection is as if you had called

`mysql_real_query()` or `mysql_query()` for the next query. This means that you can call `mysql_store_result()`, `mysql_warning_count()`, `mysql_affected_rows()`, and so forth.

If `mysql_next_result()` returns an error, no other statements are executed and there are no more results to fetch.

If your program executes stored procedures with the `CALL` SQL statement, you *must* set the `CLIENT_MULTI_RESULTS` flag, either explicitly, or implicitly by setting `CLIENT_MULTI_STATEMENTS` when you call `mysql_real_connect()`. This is because each `CALL` returns a result to indicate the call status, in addition to any results sets that might be returned by statements executed within the procedure. In addition, because `CALL` can return multiple results, you should process those results using a loop that calls `mysql_next_result()` to determine whether there are more results.

For an example that shows how to use `mysql_next_result()`, see [Section 24.2.9, “C API Handling of Multiple Statement Execution”](#).

Return Values

Return Value	Description
0	Successful and there are more results
-1	Successful and there are no more results
>0	An error occurred

Errors

- `CR_COMMANDS_OUT_OF_SYNC`

Commands were executed in an improper order. For example if you didn't call `mysql_use_result()` for a previous result set.

- `CR_SERVER_GONE_ERROR`

The MySQL server has gone away.

- `CR_SERVER_LOST`

The connection to the server was lost during the query.

- `CR_UNKNOWN_ERROR`

An unknown error occurred.

24.2.3.46. `mysql_num_fields()`

```
unsigned int mysql_num_fields(MYSQL_RES *result)
```

To pass a `MYSQL*` argument instead, use `unsigned int mysql_field_count(MYSQL *mysql)`.

Description

Returns the number of columns in a result set.

Note that you can get the number of columns either from a pointer to a result set or to a connection handle. You would use the connection handle if `mysql_store_result()` or `mysql_use_result()` returned `NULL` (and thus you have no result set pointer). In this case, you can call `mysql_field_count()` to determine whether `mysql_store_result()` should have produced a non-empty result. This allows the client program to take proper action without knowing whether the query was a `SELECT` (or `SELECT`-like) statement. The example shown here illustrates how this may be done.

See [Section 24.2.13.1, “Why `mysql_store_result\(\)` Sometimes Returns `NULL` After `mysql_query\(\)` Returns Success”](#).

Return Values

An unsigned integer representing the number of columns in a result set.

Errors

None.

Example

```
MYSQL_RES *result;
unsigned int num_fields;
unsigned int num_rows;

if (mysql_query(&mysql, query_string))
{
    // error
}
else // query succeeded, process any data returned by it
{
    result = mysql_store_result(&mysql);
    if (result) // there are rows
    {
        num_fields = mysql_num_fields(result);
        // retrieve rows, then call mysql_free_result(result)
    }
    else // mysql_store_result() returned nothing; should it have?
    {
        if (mysql_errno(&mysql))
        {
            fprintf(stderr, "Error: %s\n", mysql_error(&mysql));
        }
        else if (mysql_field_count(&mysql) == 0)
        {
            // query does not return data
            // (it was not a SELECT)
            num_rows = mysql_affected_rows(&mysql);
        }
    }
}
```

An alternative (if you know that your query should have returned a result set) is to replace the `mysql_errno(&mysql)` call with a check whether `mysql_field_count(&mysql)` is `= 0`. This happens only if something went wrong.

24.2.3.47. `mysql_num_rows()`

```
my_ulonglong mysql_num_rows(MYSQL_RES *result)
```

Description

Returns the number of rows in the result set.

The use of `mysql_num_rows()` depends on whether you use `mysql_store_result()` or `mysql_use_result()` to return the result set. If you use `mysql_store_result()`,

`mysql_num_rows()` may be called immediately. If you use `mysql_use_result()`, `mysql_num_rows()` does not return the correct value until all the rows in the result set have been retrieved.

`mysql_num_rows()` is intended for use with statements that return a result set, such as `SELECT`. For statements such as `INSERT`, `UPDATE`, or `DELETE`, the number of affected rows can be obtained with `mysql_affected_rows()`.

Return Values

The number of rows in the result set.

Errors

None.

24.2.3.48. `mysql_options()`

```
int mysql_options(MYSQL *mysql, enum mysql_option option, const char *arg)
```

Description

Can be used to set extra connect options and affect behavior for a connection. This function may be called multiple times to set several options.

`mysql_options()` should be called after `mysql_init()` and before `mysql_connect()` or `mysql_real_connect()`.

The `option` argument is the option that you want to set; the `arg` argument is the value for the option. If the option is an integer, then `arg` should point to the value of the integer.

Possible option values:

Option	Argument Type	Function
<code>MYSQL_INIT_COMMAND</code>	<code>char *</code>	Command to execute when connecting to the MySQL server. Will automatically be re-executed when reconnecting.
<code>MYSQL_OPT_COMPRESS</code>	Not used	Use the compressed client/server protocol.
<code>MYSQL_OPT_CONNECT_TIMEOUT</code>	<code>unsigned int *</code>	Connect timeout in seconds.
<code>MYSQL_OPT_GUESS_CONNECTION</code>	Not used	For an application linked against <code>libmysqld</code> , this allows the library to guess whether to use the embedded server or a remote server. “Guess” means that if the hostname is set and is not <code>localhost</code> , it uses a remote server. This behavior is the default. <code>MYSQL_OPT_USE_EMBEDDED_CONNECTION</code> and <code>MYSQL_OPT_USE_REMOTE_CONNECTION</code> can be used to override it. This option is ignored for applications linked against <code>libmysqlclient</code> .
<code>MYSQL_OPT_LOCAL_INFILE</code>	optional pointer to	If no pointer is given or if pointer

	<code>uint</code>	points to an <code>unsigned int</code> <code>!= 0</code> the command <code>LOAD LOCAL INFILE</code> is enabled.
<code>MYSQL_OPT_NAMED_PIPE</code>	Not used	Use named pipes to connect to a MySQL server on NT.
<code>MYSQL_OPT_PROTOCOL</code>	<code>unsigned int *</code>	Type of protocol to use. Should be one of the enum values of <code>mysql_protocol_type</code> defined in <code>mysql.h</code> .
<code>MYSQL_OPT_READ_TIMEOUT</code>	<code>unsigned int *</code>	Timeout for reads from server (works currently only on Windows on TCP/IP connections).
<code>MYSQL_OPT_RECONNECT</code>	<code>my_bool *</code>	Enable or disable automatic reconnection to the server if the connection is found to have been lost. Reconnect has been off by default since MySQL 5.0.3; this option is new in 5.0.13 and provides a way to set reconnection behavior explicitly.
<code>MYSQL_OPT_SET_CLIENT_IP</code>	<code>char *</code>	For an application linked against <code>libmysqld</code> (with <code>libmysqld</code> compiled with authentication support), this means that the user is considered to have connected from the specified IP address (specified as a string) for authentication purposes. This option is ignored for applications linked against <code>libmysqlclient</code> .
<code>MYSQL_OPT_SSL_VERIFY_SERVER_CERT</code>	<code>my_bool *</code>	Enable or disable verification of the server's Common Name value in its certificate against the hostname used when connecting to the server. The connection is rejected if there is a mismatch. This feature can be used to prevent man-in-the-middle attacks. Verification is disabled by default. Added in MySQL 5.1.11.
<code>MYSQL_OPT_USE_EMBEDDED_CONNECTION</code>	Not used	For an application linked against <code>libmysqld</code> , this forces the use of the embedded server for the connection. This option is ignored for applications linked against <code>libmysqlclient</code> .
<code>MYSQL_OPT_USE_REMOTE_CONNECTION</code>	Not used	For an application linked against <code>libmysqld</code> , this forces the use of a remote server for the connection. This option is ignored for applications linked against <code>libmysqlclient</code> .
<code>MYSQL_OPT_USE_RESULT</code>	Not used	This option is unused.
<code>MYSQL_OPT_WRITE_TIMEOUT</code>	<code>unsigned int *</code>	Timeout for writes to server (works currently only on Windows on TCP/IP connections).

<code>MYSQL_READ_DEFAULT_FILE</code>	<code>char *</code>	Read options from the named option file instead of from <code>my.cnf</code> .
<code>MYSQL_READ_DEFAULT_GROUP</code>	<code>char *</code>	Read options from the named group from <code>my.cnf</code> or the file specified with <code>MYSQL_READ_DEFAULT_FILE</code> .
<code>MYSQL_REPORT_DATA_TRUNCATION</code>	<code>my_bool *</code>	Enable or disable reporting of data truncation errors for prepared statements via <code>MYSQL_BIND.error</code> . (Default: enabled.)
<code>MYSQL_SECURE_AUTH</code>	<code>my_bool*</code>	Whether to connect to a server that does not support the password hashing used in MySQL 4.1.1 and later.
<code>MYSQL_SET_CHARSET_DIR</code>	<code>char*</code>	The pathname to the directory that contains character set definition files.
<code>MYSQL_SET_CHARSET_NAME</code>	<code>char*</code>	The name of the character set to use as the default character set.
<code>MYSQL_SHARED_MEMORY_BASE_NAME</code>	<code>char*</code>	Named of shared-memory object for communication to server. Should be same as the option <code>-shared-memory-base-name</code> used for the <code>mysqld</code> server you want to connect to.

Note that the `client` group is always read if you use `MYSQL_READ_DEFAULT_FILE` or `MYSQL_READ_DEFAULT_GROUP`.

The specified group in the option file may contain the following options:

Option	Description
<code>connect-timeout</code>	Connect timeout in seconds. On Linux this timeout is also used for waiting for the first answer from the server.
<code>compress</code>	Use the compressed client/server protocol.
<code>database</code>	Connect to this database if no database was specified in the connect command.
<code>debug</code>	Debug options.
<code>disable-local-infile</code>	Disable use of <code>LOAD DATA LOCAL</code> .
<code>host</code>	Default hostname.
<code>init-command</code>	Command to execute when connecting to MySQL server. Will automatically be re-executed when reconnecting.
<code>interactive-timeout</code>	Same as specifying <code>CLIENT_INTERACTIVE</code> to <code>mysql_real_connect()</code> . See Section 24.2.3.51 , “ <code>mysql_real_connect()</code> ”.
<code>local-infile[=(0 1)]</code>	If no argument or argument <code>!= 0</code> then enable use of <code>LOAD DATA LOCAL</code> .
<code>max_allowed_packet</code>	Max size of packet client can read from server.
<code>multi-results</code>	Allow multiple result sets from multiple-statement executions or stored procedures.

<code>multi-statements</code>	Allow the client to send multiple statements in a single string (separated by ';').
<code>password</code>	Default password.
<code>pipe</code>	Use named pipes to connect to a MySQL server on NT.
<code>protocol={TCP SOCKET PIPE MEMORY}</code>	The protocol to use when connecting to the server.
<code>port</code>	Default port number.
<code>return-found-rows</code>	Tell <code>mysql_info()</code> to return found rows instead of updated rows when using <code>UPDATE</code> .
<code>shared-memory-base-name=me</code>	Shared-memory name to use to connect to server (default is "MYSQL").
<code>socket</code>	Default socket file.
<code>user</code>	Default user.

Note that `timeout` has been replaced by `connect-timeout`, but `timeout` is still supported in MySQL 5.1.12-beta for backward compatibility.

For more information about option files, see [Section 4.3.2, "Using Option Files"](#).

Return Values

Zero for success. Non-zero if you used an unknown option.

Example

```
MYSQL mysql;

mysql_init(&mysql);
mysql_options(&mysql,MYSQL_OPT_COMPRESS,0);
mysql_options(&mysql,MYSQL_READ_DEFAULT_GROUP,"odbc");
if (!mysql_real_connect(&mysql,"host","user","passwd","database",0,NULL,0))
{
    fprintf(stderr,"Failed to connect to database: Error: %s\n",
            mysql_error(&mysql));
}
```

This code requests the client to use the compressed client/server protocol and read the additional options from the `odbc` section in the `my.cnf` file.

24.2.3.49. `mysql_ping()`

```
int mysql_ping(MYSQL *mysql)
```

Description

Checks whether the connection to the server is working. If the connection has gone down, an automatic reconnection is attempted.

This function can be used by clients that remain idle for a long while, to check whether the server has closed the connection and reconnect if necessary.

Return Values

Zero if the connection to the server is alive. Non-zero if an error occurred. A non-zero return does not

indicate whether the MySQL server itself is down; the connection might be broken for other reasons such as network problems.

Errors

- `CR_COMMANDS_OUT_OF_SYNC`
Commands were executed in an improper order.
- `CR_SERVER_GONE_ERROR`
The MySQL server has gone away.
- `CR_UNKNOWN_ERROR`
An unknown error occurred.

24.2.3.50. `mysql_query()`

```
int mysql_query(MYSQL *mysql, const char *query)
```

Description

Executes the SQL query pointed to by the null-terminated string `query`. Normally, the string must consist of a single SQL statement and you should not add a terminating semicolon (`;`) or `\g` to the statement. If multiple-statement execution has been enabled, the string can contain several statements separated by semicolons. See [Section 24.2.9, “C API Handling of Multiple Statement Execution”](#).

`mysql_query()` cannot be used for queries that contain binary data; you should use `mysql_real_query()` instead. (Binary data may contain the `'\0'` character, which `mysql_query()` interprets as the end of the query string.)

If you want to know whether the query should return a result set, you can use `mysql_field_count()` to check for this. See [Section 24.2.3.22, “`mysql_field_count\(\)`”](#).

Return Values

Zero if the query was successful. Non-zero if an error occurred.

Errors

- `CR_COMMANDS_OUT_OF_SYNC`
Commands were executed in an improper order.
- `CR_SERVER_GONE_ERROR`
The MySQL server has gone away.
- `CR_SERVER_LOST`
The connection to the server was lost during the query.
- `CR_UNKNOWN_ERROR`
An unknown error occurred.

24.2.3.51. `mysql_real_connect()`

```
MYSQL *mysql_real_connect(MYSQL *mysql, const char *host, const char
*user, const char *passwd, const char *db, unsigned int port, const
char *unix_socket, unsigned long client_flag)
```

Description

`mysql_real_connect()` attempts to establish a connection to a MySQL database engine running on `host`. `mysql_real_connect()` must complete successfully before you can execute any other API functions that require a valid `MYSQL` connection handle structure.

The parameters are specified as follows:

- The first parameter should be the address of an existing `MYSQL` structure. Before calling `mysql_real_connect()` you must call `mysql_init()` to initialize the `MYSQL` structure. You can change a lot of connect options with the `mysql_options()` call. See [Section 24.2.3.48](#), “`mysql_options()`”.
- The value of `host` may be either a hostname or an IP address. If `host` is `NULL` or the string “`localhost`”, a connection to the local host is assumed: For Windows, the client connects using a shared-memory connection, if the server has shared-memory connections enabled. Otherwise, TCP/IP is used. For Unix, the client connects using a Unix socket file. For local connections, you can also influence the type of connection to use with the `MYSQL_OPT_PROTOCOL` or `MYSQL_OPT_NAMED_PIPE` options to `mysql_options()`. The type of connection must be supported by the server. For a `host` value of “.” on Windows, the client connects using a named pipe, if the server has named-pipe connections enabled. If named-pipe connections are not enabled, an error occurs.
- The `user` parameter contains the user's MySQL login ID. If `user` is `NULL` or the empty string “”, the current user is assumed. Under Unix, this is the current login name. Under Windows ODBC, the current username must be specified explicitly. See the MyODBC section of [Chapter 25, Connectors](#).
- The `passwd` parameter contains the password for `user`. If `passwd` is `NULL`, only entries in the `user` table for the user that have a blank (empty) password field are checked for a match. This allows the database administrator to set up the MySQL privilege system in such a way that users get different privileges depending on whether they have specified a password.

Note: Do not attempt to encrypt the password before calling `mysql_real_connect()`; password encryption is handled automatically by the client API.

- `db` is the database name. If `db` is not `NULL`, the connection sets the default database to this value.
- If `port` is not 0, the value is used as the port number for the TCP/IP connection. Note that the `host` parameter determines the type of the connection.
- If `unix_socket` is not `NULL`, the string specifies the socket or named pipe that should be used. Note that the `host` parameter determines the type of the connection.
- The value of `client_flag` is usually 0, but can be set to a combination of the following flags to enable certain features:

Flag Name	Flag Description
<code>CLIENT_COMPRESS</code>	Use compression protocol.
<code>CLIENT_FOUND_ROWS</code>	Return the number of found (matched) rows, not the number of changed rows.

<code>CLIENT_IGNORE_SPACE</code>	Allow spaces after function names. Makes all functions names reserved words.
<code>CLIENT_INTERACTIVE</code>	Allow <code>interactive_timeout</code> seconds (instead of <code>wait_timeout</code> seconds) of inactivity before closing the connection. The client's session <code>wait_timeout</code> variable is set to the value of the session <code>interactive_timeout</code> variable.
<code>CLIENT_LOCAL_FILES</code>	Enable <code>LOAD DATA LOCAL</code> handling.
<code>CLIENT_MULTI_STATEMENTS</code>	Tell the server that the client may send multiple statements in a single string (separated by <code>;</code>). If this flag is not set, multiple-statement execution is disabled. See the note following this table for more information about this flag.
<code>CLIENT_MULTI_RESULTS</code>	Tell the server that the client can handle multiple result sets from multiple-statement executions or stored procedures. This is automatically set if <code>CLIENT_MULTI_STATEMENTS</code> is set. See the note following this table for more information about this flag.
<code>CLIENT_NO_SCHEMA</code>	Don't allow the <code>db_name.tbl_name.col_name</code> syntax. This is for ODBC. It causes the parser to generate an error if you use that syntax, which is useful for trapping bugs in some ODBC programs.
<code>CLIENT_ODBC</code>	The client is an ODBC client. This changes <code>mysqld</code> to be more ODBC-friendly.
<code>CLIENT_SSL</code>	Use SSL (encrypted protocol). This option should not be set by application programs; it is set internally in the client library. Instead, use <code>mysql_ssl_set()</code> before calling <code>mysql_real_connect()</code> .

If your program executes stored procedures with the `CALL` SQL statement, you *must* set the `CLIENT_MULTI_RESULTS` flag, either explicitly, or implicitly by setting `CLIENT_MULTI_STATEMENTS` when you call `mysql_real_connect()`. This is because each `CALL` returns a result to indicate the call status, in addition to any results sets that might be returned by statements executed within the procedure.

If you enable `CLIENT_MULTI_STATEMENTS` or `CLIENT_MULTI_RESULTS`, you should process the result for every call to `mysql_query()` or `mysql_real_query()` by using a loop that calls `mysql_next_result()` to determine whether there are more results. For an example, see [Section 24.2.9, “C API Handling of Multiple Statement Execution”](#).

For some parameters, it is possible to have the value taken from an option file rather than from an explicit value in the `mysql_real_connect()` call. To do this, call `mysql_options()` with the `MYSQL_READ_DEFAULT_FILE` or `MYSQL_READ_DEFAULT_GROUP` option before calling `mysql_real_connect()`. Then, in the `mysql_real_connect()` call, specify the “no-value” value for each parameter to be read from an option file:

- For `host`, specify a value of `NULL` or the empty string (`" "`).
- For `user`, specify a value of `NULL` or the empty string.
- For `passwd`, specify a value of `NULL`. (For the password, a value of the empty string in the `mysql_real_connect()` call cannot be overridden in an option file, because the empty string indicates explicitly that the MySQL account must have an empty password.)
- For `db`, specify a value of `NULL` or the empty string.

- For `port`, specify a value of 0.
- For `unix_socket`, specify a value of `NULL`.

If no value is found in an option file for a parameter, its default value is used as indicated in the descriptions given earlier in this section.

Return Values

A `MYSQL*` connection handle if the connection was successful, `NULL` if the connection was unsuccessful. For a successful connection, the return value is the same as the value of the first parameter.

Errors

- `CR_CONN_HOST_ERROR`
Failed to connect to the MySQL server.
- `CR_CONNECTION_ERROR`
Failed to connect to the local MySQL server.
- `CR_IPSOCK_ERROR`
Failed to create an IP socket.
- `CR_OUT_OF_MEMORY`
Out of memory.
- `CR_SOCKET_CREATE_ERROR`
Failed to create a Unix socket.
- `CR_UNKNOWN_HOST`
Failed to find the IP address for the hostname.
- `CR_VERSION_ERROR`
A protocol mismatch resulted from attempting to connect to a server with a client library that uses a different protocol version. This can happen if you use a very old client library to connect to a new server that wasn't started with the `--old-protocol` option.
- `CR_NAMEDPIPEOPEN_ERROR`
Failed to create a named pipe on Windows.
- `CR_NAMEDPIPEWAIT_ERROR`
Failed to wait for a named pipe on Windows.
- `CR_NAMEDPIPESETSTATE_ERROR`
Failed to get a pipe handler on Windows.
- `CR_SERVER_LOST`

If `connect_timeout > 0` and it took longer than `connect_timeout` seconds to connect to the server or if the server died while executing the `init-command`.

Example

```
MYSQL mysql;

mysql_init(&mysql);
mysql_options(&mysql, MYSQL_READ_DEFAULT_GROUP, "your_prog_name");
if (!mysql_real_connect(&mysql, "host", "user", "passwd", "database", 0, NULL, 0))
{
    fprintf(stderr, "Failed to connect to database: Error: %s\n",
            mysql_error(&mysql));
}
```

By using `mysql_options()` the MySQL library reads the `[client]` and `[your_prog_name]` sections in the `my.cnf` file which ensures that your program works, even if someone has set up MySQL in some non-standard way.

Note that upon connection, `mysql_real_connect()` sets the `reconnect` flag (part of the `MYSQL` structure) to a value of `1` in versions of the API older than 5.0.3, or `0` in newer versions. A value of `1` for this flag indicates that if a statement cannot be performed because of a lost connection, to try reconnecting to the server before giving up. As of MySQL 5.0.13, you can use the `MYSQL_OPT_RECONNECT` option to `mysql_options()` to control reconnection behavior.

24.2.3.52. `mysql_real_escape_string()`

```
unsigned long mysql_real_escape_string(MYSQL *mysql, char *to, const
char *from, unsigned long length)
```

Note that `mysql` must be a valid, open connection. This is needed because the escaping depends on the character set in use by the server.

Description

This function is used to create a legal SQL string that you can use in an SQL statement. See [Section 9.1.1, “Strings”](#).

The string in `from` is encoded to an escaped SQL string, taking into account the current character set of the connection. The result is placed in `to` and a terminating null byte is appended. Characters encoded are `NUL` (ASCII 0), `'\n'`, `'\r'`, `'\'`, `'\''`, `'\"'`, and Control-Z (see [Section 9.1, “Literal Values”](#)). (Strictly speaking, MySQL requires only that backslash and the quote character used to quote the string in the query be escaped. This function quotes the other characters to make them easier to read in log files.)

The string pointed to by `from` must be `length` bytes long. You must allocate the `to` buffer to be at least `length*2+1` bytes long. (In the worst case, each character may need to be encoded as using two bytes, and you need room for the terminating null byte.) When `mysql_real_escape_string()` returns, the contents of `to` is a null-terminated string. The return value is the length of the encoded string, not including the terminating null character.

If you need to change the character set of the connection, you should use the `mysql_set_character_set()` function rather than executing a `SET NAMES` (or `SET CHARACTER SET`) statement. `mysql_set_character_set()` works like `SET NAMES` but also affects the character set used by `mysql_real_escape_string()`, which `SET NAMES` does not.

Example

```
char query[1000], *end;
```

```

end = strmov(query, "INSERT INTO test_table values(");
*end++ = '\\';
end += mysql_real_escape_string(&mysql, end, "What's this", 11);
*end++ = '\\';
*end++ = ',';
*end++ = '\\';
end += mysql_real_escape_string(&mysql, end, "binary data: \\0\\r\\n", 16);
*end++ = '\\';
*end++ = ')';

if (mysql_real_query(&mysql, query, (unsigned int) (end - query)))
{
    fprintf(stderr, "Failed to insert row, Error: %s\\n",
            mysql_error(&mysql));
}

```

The `strmov()` function used in the example is included in the `mysqlclient` library and works like `strcpy()` but returns a pointer to the terminating null of the first parameter.

Return Values

The length of the value placed into `to`, not including the terminating null character.

Errors

None.

24.2.3.53. `mysql_real_query()`

```

int mysql_real_query(MYSQL *mysql, const char *query, unsigned long
length)

```

Description

Executes the SQL query pointed to by `query`, which should be a string `length` bytes long. Normally, the string must consist of a single SQL statement and you should not add a terminating semicolon (`;`) or `\g` to the statement. If multiple-statement execution has been enabled, the string can contain several statements separated by semicolons. See [Section 24.2.9, “C API Handling of Multiple Statement Execution”](#).

You **must** use `mysql_real_query()` rather than `mysql_query()` for queries that contain binary data, because binary data may contain the `'\0'` character. In addition, `mysql_real_query()` is faster than `mysql_query()` because it does not call `strlen()` on the query string.

If you want to know whether the query should return a result set, you can use `mysql_field_count()` to check for this. See [Section 24.2.3.22, “mysql_field_count\(\)”](#).

Return Values

Zero if the query was successful. Non-zero if an error occurred.

Errors

- `CR_COMMANDS_OUT_OF_SYNC`
Commands were executed in an improper order.
- `CR_SERVER_GONE_ERROR`
The MySQL server has gone away.

- `CR_SERVER_LOST`
The connection to the server was lost during the query.
- `CR_UNKNOWN_ERROR`
An unknown error occurred.

24.2.3.54. `mysql_refresh()`

```
int mysql_refresh(MYSQL *mysql, unsigned int options)
```

Description

This function flushes tables or caches, or resets replication server information. The connected user must have the `RELOAD` privilege.

The `options` argument is a bit mask composed from any combination of the following values. Multiple values can be OR'ed together to perform multiple operations with a single call.

- `REFRESH_GRANT`
Refresh the grant tables, like `FLUSH PRIVILEGES`.
- `REFRESH_LOG`
Flush the logs, like `FLUSH LOGS`.
- `REFRESH_TABLES`
Flush the table cache, like `FLUSH TABLES`.
- `REFRESH_HOSTS`
Flush the host cache, like `FLUSH HOSTS`.
- `REFRESH_STATUS`
Reset status variables, like `FLUSH STATUS`.
- `REFRESH_THREADS`
Flush the thread cache.
- `REFRESH_SLAVE`
On a slave replication server, reset the master server information and restart the slave, like `RESET SLAVE`.
- `REFRESH_MASTER`
On a master replication server, remove the binary log files listed in the binary log index and truncate the index file, like `RESET MASTER`.

Return Values

Zero for success. Non-zero if an error occurred.

Errors

- `CR_COMMANDS_OUT_OF_SYNC`
Commands were executed in an improper order.
- `CR_SERVER_GONE_ERROR`
The MySQL server has gone away.
- `CR_SERVER_LOST`
The connection to the server was lost during the query.
- `CR_UNKNOWN_ERROR`
An unknown error occurred.

24.2.3.55. `mysql_reload()`

```
int mysql_reload(MYSQL *mysql)
```

Description

Asks the MySQL server to reload the grant tables. The connected user must have the `RELOAD` privilege.

This function is deprecated. It is preferable to use `mysql_query()` to issue an SQL `FLUSH PRIVILEGES` statement instead.

Return Values

Zero for success. Non-zero if an error occurred.

Errors

- `CR_COMMANDS_OUT_OF_SYNC`
Commands were executed in an improper order.
- `CR_SERVER_GONE_ERROR`
The MySQL server has gone away.
- `CR_SERVER_LOST`
The connection to the server was lost during the query.
- `CR_UNKNOWN_ERROR`
An unknown error occurred.

24.2.3.56. `mysql_rollback()`

```
my_bool mysql_rollback(MYSQL *mysql)
```

Description

Rolls back the current transaction.

The action of this function is subject to the value of the `completion_type` system variable. In particular, if the value of `completion_type` is 2, the server performs a release after terminating a transaction and closes the client connection. The client program should call `mysql_close()` to close the connection from the client side.

Return Values

Zero if successful. Non-zero if an error occurred.

Errors

None.

24.2.3.57. `mysql_row_seek()`

```
MYSQL_ROW_OFFSET mysql_row_seek(MYSQL_RES *result, MYSQL_ROW_OFFSET offset)
```

Description

Sets the row cursor to an arbitrary row in a query result set. The `offset` value is a row offset that should be a value returned from `mysql_row_tell()` or from `mysql_row_seek()`. This value is not a row number; if you want to seek to a row within a result set by number, use `mysql_data_seek()` instead.

This function requires that the result set structure contains the entire result of the query, so `mysql_row_seek()` may be used only in conjunction with `mysql_store_result()`, not with `mysql_use_result()`.

Return Values

The previous value of the row cursor. This value may be passed to a subsequent call to `mysql_row_seek()`.

Errors

None.

24.2.3.58. `mysql_row_tell()`

```
MYSQL_ROW_OFFSET mysql_row_tell(MYSQL_RES *result)
```

Description

Returns the current position of the row cursor for the last `mysql_fetch_row()`. This value can be used as an argument to `mysql_row_seek()`.

You should use `mysql_row_tell()` only after `mysql_store_result()`, not after `mysql_use_result()`.

Return Values

The current offset of the row cursor.

Errors

None.

24.2.3.59. `mysql_select_db()`

```
int mysql_select_db(MYSQL *mysql, const char *db)
```

Description

Causes the database specified by `db` to become the default (current) database on the connection specified by `mysql`. In subsequent queries, this database is the default for table references that do not include an explicit database specifier.

`mysql_select_db()` fails unless the connected user can be authenticated as having permission to use the database.

Return Values

Zero for success. Non-zero if an error occurred.

Errors

- `CR_COMMANDS_OUT_OF_SYNC`
Commands were executed in an improper order.
- `CR_SERVER_GONE_ERROR`
The MySQL server has gone away.
- `CR_SERVER_LOST`
The connection to the server was lost during the query.
- `CR_UNKNOWN_ERROR`
An unknown error occurred.

24.2.3.60. `mysql_set_character_set()`

```
int mysql_set_character_set(MYSQL *mysql, char *csname)
```

Description

This function is used to set the default character set for the current connection. The string `csname` specifies a valid character set name. The connection collation becomes the default collation of the character set. This function works like the `SET NAMES` statement, but also sets the value of `mysql->charset`, and thus affects the character set used by `mysql_real_escape_string()`

This function was added in MySQL 5.0.7.

Return Values

Zero for success. Non-zero if an error occurred.

Example

```
MYSQL mysql;
```

```
mysql_init(&mysql);
if (!mysql_real_connect(&mysql, "host", "user", "passwd", "database", 0, NULL, 0))
{
    fprintf(stderr, "Failed to connect to database: Error: %s\n",
            mysql_error(&mysql));
}

if (!mysql_set_character_set(&mysql, "utf8"))
{
    printf("New client character set: %s\n",
            mysql_character_set_name(&mysql));
}
```

24.2.3.61. `mysql_set_local_infile_default()`

```
void
mysql_set_local_infile_default(MYSQL *mysql);
```

Description

Sets the `LOAD LOCAL DATA INFILE` handler callback functions to the defaults used internally by the C client library. The library calls this function automatically if `mysql_set_local_infile_handler()` has not been called or does not supply valid functions for each of its callbacks.

The `mysql_set_local_infile_default()` function was added in MySQL 4.1.2.

Return Values

None.

Errors

None.

24.2.3.62. `mysql_set_local_infile_handler()`

```
void
mysql_set_local_infile_handler(MYSQL *mysql,
    int (*local_infile_init)(void **, const char *, void *),
    int (*local_infile_read)(void *, char *, unsigned int),
    void (*local_infile_end)(void *),
    int (*local_infile_error)(void *, char*, unsigned int),
    void *userdata);
```

Description

This function installs callbacks to be used during the execution of `LOAD DATA LOCAL INFILE` statements. It enables application programs to exert control over local (client-side) datafile reading. The arguments are the connection handler, a set of pointers to callback functions, and a pointer to a data area that the callbacks can use to share information.

To use `mysql_set_local_infile_handler()`, you must write the following callback functions:

```
int
local_infile_init(void **ptr, const char *filename, void *userdata);
```

The initialization function. This is called once to do any setup necessary, open the datafile, allocate data structures, and so forth. The first `void**` argument is a pointer to a pointer. You can set the pointer (that is, `*ptr`) to a value that will be passed to each of the other callbacks (as a `void*`). The callbacks can use this pointed-to value to maintain state information. The `userdata` argument is the same value

that is passed to `mysql_set_local_infile_handler()`.

The initialization function should return zero for success, non-zero for an error.

```
int
local_infile_read(void *ptr, char *buf, unsigned int buf_len);
```

The data-reading function. This is called repeatedly to read the data file. `buf` points to the buffer where the read data should be stored, and `buf_len` is the maximum number of bytes that the callback can read and store in the buffer. (It can read fewer bytes, but should not read more.)

The return value is the number of bytes read, or zero when no more data could be read (this indicates EOF). Return a value less than zero if an error occurs.

```
void
local_infile_end(void *ptr)
```

The termination function. This is called once after `local_infile_read()` has returned zero (EOF) or an error. This function should deallocate any memory allocated by `local_infile_init()` and perform any other cleanup necessary. It is invoked even if the initialization function returns an error.

```
int
local_infile_error(void *ptr,
                  char *error_msg,
                  unsigned int error_msg_len);
```

The error-handling function. This is called to get a textual error message to return to the user in case any of your other functions returns an error. `error_msg` points to the buffer into which the message should be written, and `error_msg_len` is the length of the buffer. The message should be written as a null-terminated string, so the message can be at most `error_msg_len-1` bytes long.

The return value is the error number.

Typically, the other callbacks store the error message in the data structure pointed to by `ptr`, so that `local_infile_error()` can copy the message from there into `error_msg`.

After calling `mysql_set_local_infile_handler()` in your C code and passing pointers to your callback functions, you can then issue a `LOAD DATA LOCAL INFILE` statement (for example, by using `mysql_query()`). The client library automatically invokes your callbacks. The filename specified in `LOAD DATA LOCAL INFILE` will be passed as the second parameter to the `local_infile_init()` callback.

The `mysql_set_local_infile_handler()` function was added in MySQL 4.1.2.

Return Values

None.

Errors

None.

24.2.3.63. `mysql_set_server_option()`

```
int mysql_set_server_option(MYSQL *mysql, enum enum_mysql_set_option
option)
```

Description

Enables or disables an option for the connection. `option` can have one of the following values:

<code>MYSQL_OPTION_MULTI_STATEMENTS_ON</code>	Enable multiple-statement support.
<code>MYSQL_OPTION_MULTI_STATEMENTS_OFF</code>	Disable multiple-statement support.

If you enable multiple-statement support, you should retrieve results from calls to `mysql_query()` or `mysql_real_query()` by using a loop that calls `mysql_next_result()` to determine whether there are more results. For an example, see [Section 24.2.9, “C API Handling of Multiple Statement Execution”](#).

Enabling multiple-statement support with `MYSQL_OPTION_MULTI_STATEMENTS_ON` does not have quite the same effect as enabling it by passing the `CLIENT_MULTI_STATEMENTS` flag to `mysql_real_connect()`: `CLIENT_MULTI_STATEMENTS` also enables `CLIENT_MULTI_RESULTS`. If you are using the `CALL SQL` statement in your programs, multiple-result support must be enabled; this means that `MYSQL_OPTION_MULTI_STATEMENTS_ON` by itself is insufficient to allow the use of `CALL`.

Return Values

Zero for success. Non-zero if an error occurred.

Errors

- `CR_COMMANDS_OUT_OF_SYNC`
Commands were executed in an improper order.
- `CR_SERVER_GONE_ERROR`
The MySQL server has gone away.
- `CR_SERVER_LOST`
The connection to the server was lost during the query.
- `ER_UNKNOWN_COM_ERROR`
The server didn't support `mysql_set_server_option()` (which is the case that the server is older than 4.1.1) or the server didn't support the option one tried to set.

24.2.3.64. `mysql_shutdown()`

```
int mysql_shutdown(MYSQL *mysql, enum mysql_enum_shutdown_level shutdown_level)
```

Description

Asks the database server to shut down. The connected user must have `SHUTDOWN` privileges. MySQL 5.1 servers support only one type of shutdown; `shutdown_level` must be equal to `SHUTDOWN_DEFAULT`. Additional shutdown levels are planned to make it possible to choose the desired level. Dynamically linked executables which have been compiled with older versions of the `libmysqlclient` headers and call `mysql_shutdown()` need to be used with the old `libmysqlclient` dynamic library.

The shutdown process is described in [Section 5.2.7, “The Shutdown Process”](#).

Return Values

Zero for success. Non-zero if an error occurred.

Errors

- `CR_COMMANDS_OUT_OF_SYNC`
Commands were executed in an improper order.
- `CR_SERVER_GONE_ERROR`
The MySQL server has gone away.
- `CR_SERVER_LOST`
The connection to the server was lost during the query.
- `CR_UNKNOWN_ERROR`
An unknown error occurred.

24.2.3.65. `mysql_sqlstate()`

```
const char *mysql_sqlstate(MYSQL *mysql)
```

Description

Returns a null-terminated string containing the SQLSTATE error code for the last error. The error code consists of five characters. '00000' means “no error.” The values are specified by ANSI SQL and ODBC. For a list of possible values, see [Appendix B, *Error Codes and Messages*](#).

SQLSTATE values returned by `mysql_sqlstate()` differ from MySQL-specific error numbers returned by `mysql_errno()`. For example, the `mysql` client program displays errors using the following format, where 1146 is the `mysql_errno()` value and '42S02' is the corresponding `mysql_sqlstate()` value:

```
shell> SELECT * FROM no_such_table;  
ERROR 1146 (42S02): Table 'test.no_such_table' doesn't exist
```

Not all MySQL error numbers are mapped to SQLSTATE error codes. The value 'HY000' (general error) is used for unmapped error numbers.

Return Values

A null-terminated character string containing the SQLSTATE error code.

See Also

See [Section 24.2.3.14, “`mysql_errno\(\)`”](#), [Section 24.2.3.15, “`mysql_error\(\)`”](#), and [Section 24.2.7.26, “`mysql_stmt_sqlstate\(\)`”](#).

24.2.3.66. `mysql_ssl_set()`

```
int mysql_ssl_set(MYSQL *mysql, const char *key, const char *cert,  
const char *ca, const char *capath, const char *cipher)
```

Description

`mysql_ssl_set()` is used for establishing secure connections using SSL. It must be called before `mysql_real_connect()`.

`mysql_ssl_set()` does nothing unless OpenSSL support is enabled in the client library.

`mysql` is the connection handler returned from `mysql_init()`. The other parameters are specified as follows:

- `key` is the pathname to the key file.
- `cert` is the pathname to the certificate file.
- `ca` is the pathname to the certificate authority file.
- `capath` is the pathname to a directory that contains trusted SSL CA certificates in pem format.
- `cipher` is a list of allowable ciphers to use for SSL encryption.

Any unused SSL parameters may be given as `NULL`.

Return Values

This function always returns 0. If SSL setup is incorrect, `mysql_real_connect()` returns an error when you attempt to connect.

24.2.3.67. `mysql_stat()`

```
const char *mysql_stat(MYSQL *mysql)
```

Description

Returns a character string containing information similar to that provided by the `mysqladmin status` command. This includes uptime in seconds and the number of running threads, questions, reloads, and open tables.

Return Values

A character string describing the server status. `NULL` if an error occurred.

Errors

- `CR_COMMANDS_OUT_OF_SYNC`
Commands were executed in an improper order.
- `CR_SERVER_GONE_ERROR`
The MySQL server has gone away.
- `CR_SERVER_LOST`
The connection to the server was lost during the query.
- `CR_UNKNOWN_ERROR`

An unknown error occurred.

24.2.3.68. `mysql_store_result()`

```
MYSQL_RES *mysql_store_result(MYSQL *mysql)
```

Description

You must call `mysql_store_result()` or `mysql_use_result()` for every query that successfully retrieves data (`SELECT`, `SHOW`, `DESCRIBE`, `EXPLAIN`, `CHECK TABLE`, and so forth).

You don't have to call `mysql_store_result()` or `mysql_use_result()` for other queries, but it does not do any harm or cause any notable performance degradation if you call `mysql_store_result()` in all cases. You can detect if the query didn't have a result set by checking if `mysql_store_result()` returns 0 (more about this later on).

If you want to know whether the query should return a result set, you can use `mysql_field_count()` to check for this. See [Section 24.2.3.22, “mysql_field_count\(\)”](#).

`mysql_store_result()` reads the entire result of a query to the client, allocates a `MYSQL_RES` structure, and places the result into this structure.

`mysql_store_result()` returns a null pointer if the query didn't return a result set (if the query was, for example, an `INSERT` statement).

`mysql_store_result()` also returns a null pointer if reading of the result set failed. You can check whether an error occurred by checking if `mysql_error()` returns a non-empty string, if `mysql_errno()` returns non-zero, or if `mysql_field_count()` returns zero.

An empty result set is returned if there are no rows returned. (An empty result set differs from a null pointer as a return value.)

Once you have called `mysql_store_result()` and got a result back that isn't a null pointer, you may call `mysql_num_rows()` to find out how many rows are in the result set.

You can call `mysql_fetch_row()` to fetch rows from the result set, or `mysql_row_seek()` and `mysql_row_tell()` to obtain or set the current row position within the result set.

You must call `mysql_free_result()` once you are done with the result set.

See [Section 24.2.13.1, “Why mysql_store_result\(\) Sometimes Returns NULL After mysql_query\(\) Returns Success”](#).

Return Values

A `MYSQL_RES` result structure with the results. `NULL` if an error occurred.

Errors

`mysql_store_result()` resets `mysql_error()` and `mysql_errno()` if it succeeds.

- `CR_COMMANDS_OUT_OF_SYNC`
Commands were executed in an improper order.
- `CR_OUT_OF_MEMORY`

Out of memory.

- `CR_SERVER_GONE_ERROR`

The MySQL server has gone away.

- `CR_SERVER_LOST`

The connection to the server was lost during the query.

- `CR_UNKNOWN_ERROR`

An unknown error occurred.

24.2.3.69. `mysql_thread_id()`

```
unsigned long mysql_thread_id(MYSQL *mysql)
```

Description

Returns the thread ID of the current connection. This value can be used as an argument to `mysql_kill()` to kill the thread.

If the connection is lost and you reconnect with `mysql_ping()`, the thread ID changes. This means you should not get the thread ID and store it for later. You should get it when you need it.

Return Values

The thread ID of the current connection.

Errors

None.

24.2.3.70. `mysql_use_result()`

```
MYSQL_RES *mysql_use_result(MYSQL *mysql)
```

Description

You must call `mysql_store_result()` or `mysql_use_result()` for every query that successfully retrieves data (`SELECT`, `SHOW`, `DESCRIBE`, `EXPLAIN`).

`mysql_use_result()` initiates a result set retrieval but does not actually read the result set into the client like `mysql_store_result()` does. Instead, each row must be retrieved individually by making calls to `mysql_fetch_row()`. This reads the result of a query directly from the server without storing it in a temporary table or local buffer, which is somewhat faster and uses much less memory than `mysql_store_result()`. The client allocates memory only for the current row and a communication buffer that may grow up to `max_allowed_packet` bytes.

On the other hand, you shouldn't use `mysql_use_result()` if you are doing a lot of processing for each row on the client side, or if the output is sent to a screen on which the user may type a `^S` (stop scroll). This ties up the server and prevent other threads from updating any tables from which the data is being fetched.

When using `mysql_use_result()`, you must execute `mysql_fetch_row()` until a `NULL` value is returned, otherwise, the unfetched rows are returned as part of the result set for your next query. The

C API gives the error `Commands out of sync; you can't run this command now if you forget to do this!`

You may not use `mysql_data_seek()`, `mysql_row_seek()`, `mysql_row_tell()`, `mysql_num_rows()`, or `mysql_affected_rows()` with a result returned from `mysql_use_result()`, nor may you issue other queries until `mysql_use_result()` has finished. (However, after you have fetched all the rows, `mysql_num_rows()` accurately returns the number of rows fetched.)

You must call `mysql_free_result()` once you are done with the result set.

When using the `libmysqld` embedded server, the memory benefits are essentially lost because memory usage incrementally increases with each row retrieved until `mysql_free_result()` is called.

Return Values

A `MYSQL_RES` result structure. `NULL` if an error occurred.

Errors

`mysql_use_result()` resets `mysql_error()` and `mysql_errno()` if it succeeds.

- `CR_COMMANDS_OUT_OF_SYNC`
Commands were executed in an improper order.
- `CR_OUT_OF_MEMORY`
Out of memory.
- `CR_SERVER_GONE_ERROR`
The MySQL server has gone away.
- `CR_SERVER_LOST`
The connection to the server was lost during the query.
- `CR_UNKNOWN_ERROR`
An unknown error occurred.

24.2.3.71. `mysql_warning_count()`

```
unsigned int mysql_warning_count(MYSQL *mysql)
```

Description

Returns the number of warnings generated during execution of the previous SQL statement.

Return Values

The warning count.

Errors

None.

24.2.4. C API Prepared Statements

The MySQL client/server protocol provides for the use of prepared statements. This capability uses the `MYSQL_STMT` statement handler data structure returned by the `mysql_stmt_init()` initialization function. Prepared execution is an efficient way to execute a statement more than once. The statement is first parsed to prepare it for execution. Then it is executed one or more times at a later time, using the statement handle returned by the initialization function.

Prepared execution is faster than direct execution for statements executed more than once, primarily because the query is parsed only once. In the case of direct execution, the query is parsed every time it is executed. Prepared execution also can provide a reduction of network traffic because for each execution of the prepared statement, it is necessary only to send the data for the parameters.

Prepared statements might not provide a performance increase in some situations. For best results, test your application both with prepared and non-prepared statements and choose whichever yields best performance.

Another advantage of prepared statements is that it uses a binary protocol that makes data transfer between client and server more efficient.

The following statements can be used as prepared statements: `CREATE TABLE`, `DELETE`, `DO`, `INSERT`, `REPLACE`, `SELECT`, `SET`, `UPDATE`, and most `SHOW` statements. Other statements are not supported in MySQL 5.1.

24.2.5. C API Prepared Statement Data types

Prepared statements mainly use the `MYSQL_STMT` and `MYSQL_BIND` data structures. A third structure, `MYSQL_TIME`, is used to transfer temporal data.

- `MYSQL_STMT`

This structure represents a prepared statement. A statement is created by calling `mysql_stmt_init()`, which returns a statement handle (that is, a pointer to a `MYSQL_STMT`). The handle is used for all subsequent statement-related functions until you close it with `mysql_stmt_close()`.

The `MYSQL_STMT` structure has no members that are for application use. Also, you should not try to make a copy of a `MYSQL_STMT` structure. There is no guarantee that such a copy will be usable.

Multiple statement handles can be associated with a single connection. The limit on the number of handles depends on the available system resources.

- `MYSQL_BIND`

This structure is used both for statement input (data values sent to the server) and output (result values returned from the server). For input, it is used with `mysql_stmt_bind_param()` to bind parameter data values to buffers for use by `mysql_stmt_execute()`. For output, it is used with `mysql_stmt_bind_result()` to bind result set buffers for use in fetching rows with `mysql_stmt_fetch()`.

To use a `MYSQL_BIND` structure, you should zero its contents to initialize it, and then set its members appropriately. For example, to declare and initialize an array of three `MYSQL_BIND` structures, use this code:

```
MYSQL_BIND bind[3];
memset(bind, 0, sizeof(bind));
```

The `MYSQL_BIND` structure contains the following members for use by application programs. Each is used both for input and for output, although sometimes for different purposes depending on the direction of data transfer.

- `enum enum_field_types buffer_type`

The type of the buffer. The allowable `buffer_type` values are listed later in this section. For input, `buffer_type` indicates what type of value you are binding to a statement parameter. For output, it indicates what type of value you expect to receive in a result buffer.

- `void *buffer`

For input, this is a pointer to the buffer in which a statement parameter's data value is stored. For output, it is a pointer to the buffer in which to return a result set column value. For numeric data types, `buffer` should point to a variable of the proper C type. (If you are associating the variable with a column that has the `UNSIGNED` attribute, the variable should be an `unsigned C` type. Indicate whether the variable is signed or unsigned by using the `is_unsigned` member, described later in this list.) For date and time data types, `buffer` should point to a `MYSQL_TIME` structure. For character and binary string data types, `buffer` should point to a character buffer.

- `unsigned long buffer_length`

The actual size of `*buffer` in bytes. This indicates the maximum amount of data that can be stored in the buffer. For character and binary C data, the `buffer_length` value specifies the length of `*buffer` when used with `mysql_stmt_bind_param()`, or the maximum number of data bytes that can be fetched into the buffer when used with `mysql_stmt_bind_result()`.

- `unsigned long *length`

A pointer to an `unsigned long` variable that indicates the actual number of bytes of data stored in `*buffer`. `length` is used for character or binary C data. For input parameter data binding, `length` points to an `unsigned long` variable that indicates the length of the parameter value stored in `*buffer`; this is used by `mysql_stmt_execute()`. For output value binding, the return value of `mysql_stmt_fetch()` determines the interpretation of the length. If `mysql_stmt_fetch()` returns 0, `*length` indicates the actual length of the parameter value. If `mysql_stmt_fetch()` returns `MYSQL_DATA_TRUNCATED`, `*length` indicates the non-truncated length of the parameter value. In this case, the minimum of `*length` and `buffer_length` indicates the actual length of the value.

`length` is ignored for numeric and temporal data types because the length of the data value is determined by the `buffer_type` value.

- `my_bool *is_null`

This member points to a `my_bool` variable that is true if a value is `NULL`, false if it is not `NULL`. For input, set `*is_null` to true to indicate that you are passing a `NULL` value as a statement parameter. For output, this value is set to true after you fetch a row if the result set column value returned from the statement is `NULL`.

`is_null` is a pointer to a boolean rather than a boolean scalar so that it can be used in the following way:

- If your data values are always `NULL`, use `MYSQL_TYPE_NULL` to bind the column.
- If your data values are always `NOT NULL`, set `is_null = (my_bool*) 0`.

- In all other cases, you should set `is_null` to the address of a `my_bool` variable and change that variable's value appropriately between executions to indicate whether data values are `NULL` or `NOT NULL`.

- `my_bool is_unsigned`

This member is used for integer types. (These correspond to the `MYSQL_TYPE_TINY`, `MYSQL_TYPE_SHORT`, `MYSQL_TYPE_LONG`, and `MYSQL_TYPE_LONGLONG` type codes.) `is_unsigned` should be set to true for unsigned types and false for signed types.

- `my_bool *error`

For output, set this member to point to a `my_bool` variable to have truncation information for the parameter stored there after a row fetching operation. (Truncation reporting is enabled by default, but can be controlled by calling `mysql_options()` with the `MYSQL_REPORT_DATA_TRUNCATION` option.) When truncation reporting is enabled, `mysql_stmt_fetch()` returns `MYSQL_DATA_TRUNCATED` and `*error` is true in the `MYSQL_BIND` structures for parameters in which truncation occurred. Truncation indicates loss of sign or significant digits, or that a string was too long to fit in a column.

- `MYSQL_TIME`

This structure is used to send and receive `DATE`, `TIME`, `DATETIME`, and `TIMESTAMP` data directly to and from the server. This is done by setting the `buffer_type` member of a `MYSQL_BIND` structure to one of the temporal types, and setting the `buffer` member to point to a `MYSQL_TIME` structure.

The `MYSQL_TIME` structure contains the following members:

- `unsigned int year`

The year.

- `unsigned int month`

The month of the year.

- `unsigned int day`

The day of the month.

- `unsigned int hour`

The hour of the day.

- `unsigned int minute`

The minute of the hour.

- `unsigned int second`

The second of the minute.

- `my_bool neg`

A boolean flag to indicate whether the time is negative.

- `unsigned long second_part`

The fractional part of the second. This member currently is unused.

Only those parts of a `MYSQL_TIME` structure that apply to a given type of temporal value are used: The `year`, `month`, and `day` elements are used for `DATE`, `DATETIME`, and `TIMESTAMP` values. The `hour`, `minute`, and `second` elements are used for `TIME`, `DATETIME`, and `TIMESTAMP` values. See [Section 24.2.10, “C API Handling of Date and Time Values”](#).

The following table shows the allowable values that may be specified in the `buffer_type` member of `MYSQL_BIND` structures. The table also shows those SQL types that correspond most closely to each `buffer_type` value, and, for numeric and temporal types, the corresponding recommended C type.

The types are “recommended” because implicit type conversion may be performed in both directions. The `buffer_type` value controls the conversion that will be performed. For example, to fetch a SQL `MEDIUMINT` column value, you can specify a `buffer_type` value of `MYSQL_TYPE_LONG` and use a C variable of type `int` as the destination buffer. If you fetch a numeric column with a value of 255 into a `char[4]` character array, specify a `buffer_type` value of `MYSQL_TYPE_STRING` and the resulting value in the array will be a 4-byte string containing `'255\0'`.

To distinguish between binary and non-binary data for string data types, check whether the `charsetnr` value of the result set metadata is 63. If so, the character set is `binary`, which indicates binary rather than non-binary data. This is how to distinguish between `BINARY` and `CHAR`, `VARBINARY` and `VARCHAR`, and `BLOB` and `TEXT`.

<code>buffer_type</code> Value	SQL Type	Recommended C Type
<code>MYSQL_TYPE_BIT</code>	<code>BIT</code>	<code>unsigned long long int</code>
<code>MYSQL_TYPE_TINY</code>	<code>TINYINT</code>	<code>unsigned char</code>
<code>MYSQL_TYPE_SHORT</code>	<code>SMALLINT</code>	<code>short int</code>
<code>MYSQL_TYPE_LONG</code>	<code>INT</code>	<code>int</code>
<code>MYSQL_TYPE_LONGLONG</code>	<code>BIGINT</code>	<code>long long int</code>
<code>MYSQL_TYPE_FLOAT</code>	<code>FLOAT</code>	<code>float</code>
<code>MYSQL_TYPE_DOUBLE</code>	<code>DOUBLE</code>	<code>double</code>
<code>MYSQL_TYPE_NEWDECIMAL</code>	<code>DECIMAL</code>	<code>char[]</code>
<code>MYSQL_TYPE_TIME</code>	<code>TIME</code>	<code>MYSQL_TIME</code>
<code>MYSQL_TYPE_DATE</code>	<code>DATE</code>	<code>MYSQL_TIME</code>
<code>MYSQL_TYPE_DATETIME</code>	<code>DATETIME</code>	<code>MYSQL_TIME</code>
<code>MYSQL_TYPE_TIMESTAMP</code>	<code>TIMESTAMP</code>	<code>MYSQL_TIME</code>
<code>MYSQL_TYPE_STRING</code>	<code>CHAR/BINARY</code>	<code>char[]</code>
<code>MYSQL_TYPE_VAR_STRING</code>	<code>VARCHAR/VARBINARY</code>	<code>char[]</code>
<code>MYSQL_TYPE_TINY_BLOB</code>	<code>TINYBLOB/TINYTEXT</code>	<code>char[]</code>
<code>MYSQL_TYPE_BLOB</code>	<code>BLOB/TEXT</code>	<code>char[]</code>
<code>MYSQL_TYPE_MEDIUM_BLOB</code>	<code>MEDIUMBLOB/MEDIUMTEXT</code>	<code>char[]</code>
<code>MYSQL_TYPE_LONG_BLOB</code>	<code>LOB/LOBTEXT</code>	<code>char[]</code>

24.2.6. C API Prepared Statement Function Overview

The functions available for prepared statement processing are summarized here and described in greater

detail in a later section. See [Section 24.2.7, “C API Prepared Statement Function Descriptions”](#).

Function	Description
mysql_stmt_affected_rows()	Returns the number of rows changes, deleted, or inserted by prepared UPDATE , DELETE , or INSERT statement.
mysql_stmt_attr_get()	Get value of an attribute for a prepared statement.
mysql_stmt_attr_set()	Sets an attribute for a prepared statement.
mysql_stmt_bind_param()	Associates application data buffers with the parameter markers in a prepared SQL statement.
mysql_stmt_bind_result()	Associates application data buffers with columns in the result set.
mysql_stmt_close()	Frees memory used by prepared statement.
mysql_stmt_data_seek()	Seeks to an arbitrary row number in a statement result set.
mysql_stmt_errno()	Returns the error number for the last statement execution.
mysql_stmt_error()	Returns the error message for the last statement execution.
mysql_stmt_execute()	Executes the prepared statement.
mysql_stmt_fetch()	Fetches the next row of data from the result set and returns data for all bound columns.
mysql_stmt_fetch_column()	Fetch data for one column of the current row of the result set.
mysql_stmt_field_count()	Returns the number of result columns for the most recent statement.
mysql_stmt_free_result()	Free the resources allocated to the statement handle.
mysql_stmt_init()	Allocates memory for MYSQL_STMT structure and initializes it.
mysql_stmt_insert_id()	Returns the ID generated for an AUTO_INCREMENT column by prepared statement.
mysql_stmt_num_rows()	Returns total rows from the statement buffered result set.
mysql_stmt_param_count()	Returns the number of parameters in a prepared SQL statement.
mysql_stmt_param_metadata()	(Return parameter metadata in the form of a result set.) Currently, this function does nothing.
mysql_stmt_prepare()	Prepares an SQL string for execution.
mysql_stmt_reset()	Reset the statement buffers in the server.
mysql_stmt_result_metadata()	Returns prepared statement metadata in the form of a result set.
mysql_stmt_row_seek()	Seeks to a row offset in a statement result set, using value returned from mysql_stmt_row_tell() .
mysql_stmt_row_tell()	Returns the statement row cursor position.
mysql_stmt_send_long_data()	Sends long data in chunks to server.
mysql_stmt_sqlstate()	Returns the SQLSTATE error code for the last statement execution.
mysql_stmt_store_result()	Retrieves the complete result set to the client.

Call [mysql_stmt_init\(\)](#) to create a statement handle, then [mysql_stmt_prepare](#) to prepare it, [mysql_stmt_bind_param\(\)](#) to supply the parameter data, and [mysql_stmt_execute\(\)](#) to execute the statement. You can repeat the [mysql_stmt_execute\(\)](#) by changing parameter values in the respective buffers supplied through [mysql_stmt_bind_param\(\)](#).

If the statement is a [SELECT](#) or any other statement that produces a result set, [mysql_stmt_prepare\(\)](#) also returns the result set metadata information in the form of a [MYSQL_RES](#) result set through [mysql_stmt_result_metadata\(\)](#).

You can supply the result buffers using `mysql_stmt_bind_result()`, so that the `mysql_stmt_fetch()` automatically returns data to these buffers. This is row-by-row fetching.

You can also send the text or binary data in chunks to server using `mysql_stmt_send_long_data()`. See [Section 24.2.7.25](#), “`mysql_stmt_send_long_data()`”.

When statement execution has been completed, the statement handle must be closed using `mysql_stmt_close()` so that all resources associated with it can be freed.

If you obtained a `SELECT` statement's result set metadata by calling `mysql_stmt_result_metadata()`, you should also free the metadata using `mysql_free_result()`.

Execution Steps

To prepare and execute a statement, an application follows these steps:

1. Create a prepared statement handle with `mysql_stmt_init()`. To prepare the statement on the server, call `mysql_stmt_prepare()` and pass it a string containing the SQL statement.
2. If the statement produces a result set, call `mysql_stmt_result_metadata()` to obtain the result set metadata. This metadata is itself in the form of result set, albeit a separate one from the one that contains the rows returned by the query. The metadata result set indicates how many columns are in the result and contains information about each column.
3. Set the values of any parameters using `mysql_stmt_bind_param()`. All parameters must be set. Otherwise, statement execution returns an error or produces unexpected results.
4. Call `mysql_stmt_execute()` to execute the statement.
5. If the statement produces a result set, bind the data buffers to use for retrieving the row values by calling `mysql_stmt_bind_result()`.
6. Fetch the data into the buffers row by row by calling `mysql_stmt_fetch()` repeatedly until no more rows are found.
7. Repeat steps 3 through 6 as necessary, by changing the parameter values and re-executing the statement.

When `mysql_stmt_prepare()` is called, the MySQL client/server protocol performs these actions:

- The server parses the statement and sends the okay status back to the client by assigning a statement ID. It also sends total number of parameters, a column count, and its metadata if it is a result set oriented statement. All syntax and semantics of the statement are checked by the server during this call.
- The client uses this statement ID for the further operations, so that the server can identify the statement from among its pool of statements.

When `mysql_stmt_execute()` is called, the MySQL client/server protocol performs these actions:

- The client uses the statement handle and sends the parameter data to the server.
- The server identifies the statement using the ID provided by the client, replaces the parameter markers with the newly supplied data, and executes the statement. If the statement produces a result set,

the server sends the data back to the client. Otherwise, it sends an okay status and total number of rows changed, deleted, or inserted.

When `mysql_stmt_fetch()` is called, the MySQL client/server protocol performs these actions:

- The client reads the data from the packet row by row and places it into the application data buffers by doing the necessary conversions. If the application buffer type is same as that of the field type returned from the server, the conversions are straightforward.

If an error occurs, you can get the statement error code, error message, and SQLSTATE value using `mysql_stmt_errno()`, `mysql_stmt_error()`, and `mysql_stmt_sqlstate()`, respectively.

Prepared Statement Logging

For prepared statements that are executed with the `mysql_stmt_prepare()` and `mysql_stmt_execute()` C API functions, the server writes `Prepare` and `Execute` lines to the general query log so that you can tell when statements are prepared and executed.

Suppose that you prepare and execute a statement as follows:

1. Call `mysql_stmt_prepare()` to prepare the statement string "SELECT ?".
2. Call `mysql_stmt_bind_param()` to bind the value 3 to the parameter in the prepared statement.
3. Call `mysql_stmt_execute()` to execute the prepared statement.

As a result of the preceding calls, the server writes the following lines to the general query log:

```
Prepare [1] SELECT ?
Execute [1] SELECT 3
```

Each `Prepare` and `Execute` line in the log is tagged with a `[N]` statement identifier so that you can keep track of which prepared statement is being logged. `N` is a positive integer. If there are multiple prepared statements active simultaneously for the client, `N` may be greater than 1. Each `Execute` lines shows a prepared statement after substitution of data values for `?` parameters.

Version notes: `Prepare` lines are displayed without `[N]` before MySQL 4.1.10. `Execute` lines are not displayed at all before MySQL 4.1.10.

24.2.7. C API Prepared Statement Function Descriptions

To prepare and execute queries, use the functions described in detail in the following sections.

Note that all functions operating with a `MYSQL_STMT` structure begin with the prefix `mysql_stmt_`.

To create a `MYSQL_STMT` handle, use the `mysql_stmt_init()` function.

24.2.7.1. `mysql_stmt_affected_rows()`

```
my_ulonglong mysql_stmt_affected_rows(MYSQL_STMT *stmt)
```

Description

Returns the total number of rows changed, deleted, or inserted by the last executed statement. May be called immediately after `mysql_stmt_execute()` for `UPDATE`, `DELETE`, or `INSERT` statements. For `SELECT` statements, `mysql_stmt_affected_rows()` works like `mysql_num_rows()`.

Return Values

An integer greater than zero indicates the number of rows affected or retrieved. Zero indicates that no records were updated for an `UPDATE` statement, no rows matched the `WHERE` clause in the query, or that no query has yet been executed. -1 indicates that the query returned an error or that, for a `SELECT` query, `mysql_stmt_affected_rows()` was called prior to calling `mysql_stmt_store_result()`. Because `mysql_stmt_affected_rows()` returns an unsigned value, you can check for -1 by comparing the return value to `(my_ulonglong)-1` (or to `(my_ulonglong)~0`, which is equivalent).

See [Section 24.2.3.1](#), “`mysql_affected_rows()`”, for additional information on the return value.

Errors

None.

Example

For the usage of `mysql_stmt_affected_rows()`, refer to the Example from [Section 24.2.7.10](#), “`mysql_stmt_execute()`”.

24.2.7.2. `mysql_stmt_attr_get()`

```
int mysql_stmt_attr_get(MYSQL_STMT *stmt, enum enum_stmt_attr_type option, void *arg)
```

Description

Can be used to get the current value for a statement attribute.

The `option` argument is the option that you want to get; the `arg` should point to a variable that should contain the option value. If the option is an integer, then `arg` should point to the value of the integer.

See [Section 24.2.7.3](#), “`mysql_stmt_attr_set()`”, for a list of options and option types.

Return Values

0 if okay. Non-zero if `option` is unknown.

Errors

None.

24.2.7.3. `mysql_stmt_attr_set()`

```
int mysql_stmt_attr_set(MYSQL_STMT *stmt, enum enum_stmt_attr_type option, const void *arg)
```

Description

Can be used to affect behavior for a prepared statement. This function may be called multiple times to set several options.

The `option` argument is the option that you want to set; the `arg` argument is the value for the option. If the option is an integer, then `arg` should point to the value of the integer.

Possible `option` values:

Option	Argument Type	Function
<code>STMT_ATTR_UPDATE_MAX_LENGTH</code>	<code>my_bool *</code>	If set to 1: Update metadata <code>MYSQL_FIELD->max_length</code> in <code>mysql_stmt_store_result()</code> .
<code>STMT_ATTR_CURSOR_TYPE</code>	<code>unsigned long *</code>	Type of cursor to open for statement when <code>mysql_stmt_execute()</code> is invoked. <code>*arg</code> can be <code>CURSOR_TYPE_NO_CURSOR</code> (the default) or <code>CURSOR_TYPE_READ_ONLY</code> .
<code>STMT_ATTR_PREFETCH_ROWS</code>	<code>unsigned long *</code>	Number of rows to fetch from server at a time when using a cursor. <code>*arg</code> can be in the range from 1 to the maximum value of <code>unsigned long</code> . The default is 1.

If you use the `STMT_ATTR_CURSOR_TYPE` option with `CURSOR_TYPE_READ_ONLY`, a cursor is opened for the statement when you invoke `mysql_stmt_execute()`. If there is already an open cursor from a previous `mysql_stmt_execute()` call, it closes the cursor before opening a new one. `mysql_stmt_reset()` also closes any open cursor before preparing the statement for re-execution. `mysql_stmt_free_result()` closes any open cursor.

If you open a cursor for a prepared statement, `mysql_stmt_store_result()` is unnecessary, because that function causes the result set to be buffered on the client side.

The `STMT_ATTR_CURSOR_TYPE` option was added in MySQL 5.0.2. The `STMT_ATTR_PREFETCH_ROWS` option was added in MySQL 5.0.6.

Return Values

0 if okay. Non-zero if `option` is unknown.

Errors

None.

Example

The following example opens a cursor for a prepared statement and sets the number of rows to fetch at a time to 5:

```
MYSQL_STMT *stmt;
int rc;
unsigned long type;
unsigned long prefetch_rows = 5;

stmt = mysql_stmt_init(mysql);
type = (unsigned long) CURSOR_TYPE_READ_ONLY;
rc = mysql_stmt_attr_set(stmt, STMT_ATTR_CURSOR_TYPE, (void*) &type);
/* ... check return value ... */
rc = mysql_stmt_attr_set(stmt, STMT_ATTR_PREFETCH_ROWS,
                        (void*) &prefetch_rows);
/* ... check return value ... */
```

24.2.7.4. `mysql_stmt_bind_param()`

```
my_bool mysql_stmt_bind_param(MYSQL_STMT *stmt, MYSQL_BIND *bind)
```

Description

`mysql_stmt_bind_param()` is used to bind data for the parameter markers in the SQL statement that was passed to `mysql_stmt_prepare()`. It uses `MYSQL_BIND` structures to supply the data. `bind` is the address of an array of `MYSQL_BIND` structures. The client library expects the array to contain an element for each ‘?’ parameter marker that is present in the query.

Suppose that you prepare the following statement:

```
INSERT INTO mytbl VALUES(?,?,?)
```

When you bind the parameters, the array of `MYSQL_BIND` structures must contain three elements, and can be declared like this:

```
MYSQL_BIND bind[3];
```

The members of each `MYSQL_BIND` element that should be set are described in [Section 24.2.5, “C API Prepared Statement Data types”](#).

Return Values

Zero if the bind was successful. Non-zero if an error occurred.

Errors

- `CR_INVALID_BUFFER_USE`
Indicates if the bind is to supply the long data in chunks and if the buffer type is non string or binary.
- `CR_UNSUPPORTED_PARAM_TYPE`
The conversion is not supported. Possibly the `buffer_type` value is illegal or is not one of the supported types.
- `CR_OUT_OF_MEMORY`
Out of memory.
- `CR_UNKNOWN_ERROR`
An unknown error occurred.

Example

For the usage of `mysql_stmt_bind_param()`, refer to the Example from [Section 24.2.7.10, “mysql_stmt_execute\(\)”](#).

24.2.7.5. `mysql_stmt_bind_result()`

```
my_bool mysql_stmt_bind_result(MYSQL_STMT *stmt, MYSQL_BIND *bind)
```

Description

`mysql_stmt_bind_result()` is used to associate (bind) columns in the result set to data buffers and length buffers. When `mysql_stmt_fetch()` is called to fetch data, the MySQL client/server protocol places the data for the bound columns into the specified buffers.

All columns must be bound to buffers prior to calling `mysql_stmt_fetch()`. `bind` is the address of an array of `MYSQL_BIND` structures. The client library expects the array to contain an element for each column of the result set. If you do not bind columns to `MYSQL_BIND` structures, `mysql_stmt_fetch()` simply ignores the data fetch. The buffers should be large enough to hold the data values, because the protocol doesn't return data values in chunks.

A column can be bound or rebound at any time, even after a result set has been partially retrieved. The new binding takes effect the next time `mysql_stmt_fetch()` is called. Suppose that an application binds the columns in a result set and calls `mysql_stmt_fetch()`. The client/server protocol returns data in the bound buffers. Then suppose that the application binds the columns to a different set of buffers. The protocol does not place data into the newly bound buffers until the next call to `mysql_stmt_fetch()` occurs.

To bind a column, an application calls `mysql_stmt_bind_result()` and passes the type, address, and the address of the length buffer. The members of each `MYSQL_BIND` element that should be set are described in [Section 24.2.5, "C API Prepared Statement Data types"](#).

Return Values

Zero if the bind was successful. Non-zero if an error occurred.

Errors

- `CR_UNSUPPORTED_PARAM_TYPE`

The conversion is not supported. Possibly the `buffer_type` value is illegal or is not one of the supported types.

- `CR_OUT_OF_MEMORY`

Out of memory.

- `CR_UNKNOWN_ERROR`

An unknown error occurred.

Example

For the usage of `mysql_stmt_bind_result()`, refer to the Example from [Section 24.2.7.11, "mysql_stmt_fetch\(\)"](#).

24.2.7.6. `mysql_stmt_close()`

```
my_bool mysql_stmt_close(MYSQL_STMT *)
```

Description

Closes the prepared statement. `mysql_stmt_close()` also deallocates the statement handle pointed to by `stmt`.

If the current statement has pending or unread results, this function cancels them so that the next query can be executed.

Return Values

Zero if the statement was freed successfully. Non-zero if an error occurred.

Errors

- `CR_SERVER_GONE_ERROR`
The MySQL server has gone away.
- `CR_UNKNOWN_ERROR`
An unknown error occurred.

Example

For the usage of `mysql_stmt_close()`, refer to the Example from [Section 24.2.7.10](#), “`mysql_stmt_execute()`”.

24.2.7.7. `mysql_stmt_data_seek()`

```
void mysql_stmt_data_seek(MYSQL_STMT *stmt, my_ulonglong offset)
```

Description

Seeks to an arbitrary row in a statement result set. The `offset` value is a row number and should be in the range from 0 to `mysql_stmt_num_rows(stmt) - 1`.

This function requires that the statement result set structure contains the entire result of the last executed query, so `mysql_stmt_data_seek()` may be used only in conjunction with `mysql_stmt_store_result()`.

Return Values

None.

Errors

None.

24.2.7.8. `mysql_stmt_errno()`

```
unsigned int mysql_stmt_errno(MYSQL_STMT *stmt)
```

Description

For the statement specified by `stmt`, `mysql_stmt_errno()` returns the error code for the most recently invoked statement API function that can succeed or fail. A return value of zero means that no error occurred. Client error message numbers are listed in the MySQL `errmsg.h` header file. Server error message numbers are listed in `mysqld_error.h`. Errors also are listed at [Appendix B, *Error Codes and Messages*](#).

Return Values

An error code value. Zero if no error occurred.

Errors

None.

24.2.7.9. `mysql_stmt_error()`

```
const char *mysql_stmt_error(MYSQL_STMT *stmt)
```

Description

For the statement specified by `stmt`, `mysql_stmt_error()` returns a null-terminated string containing the error message for the most recently invoked statement API function that can succeed or fail. An empty string (" ") is returned if no error occurred. This means the following two tests are equivalent:

```
if (mysql_stmt_errno(stmt))
{
    // an error occurred
}

if (mysql_stmt_error(stmt)[0])
{
    // an error occurred
}
```

The language of the client error messages may be changed by recompiling the MySQL client library. Currently, you can choose error messages in several different languages.

Return Values

A character string that describes the error. An empty string if no error occurred.

Errors

None.

24.2.7.10. `mysql_stmt_execute()`

```
int mysql_stmt_execute(MYSQL_STMT *stmt)
```

Description

`mysql_stmt_execute()` executes the prepared query associated with the statement handle. The currently bound parameter marker values are sent to server during this call, and the server replaces the markers with this newly supplied data.

If the statement is an `UPDATE`, `DELETE`, or `INSERT`, the total number of changed, deleted, or inserted rows can be found by calling `mysql_stmt_affected_rows()`. If this is a statement such as `SELECT` that generates a result set, you must call `mysql_stmt_fetch()` to fetch the data prior to calling any other functions that result in query processing. For more information on how to fetch the results, refer to [Section 24.2.7.11](#), “`mysql_stmt_fetch()`”.

For statements that generate a result set, you can request that `mysql_stmt_execute()` open a cursor for the statement by calling `mysql_stmt_attr_set()` before executing the statement. If you execute a statement multiple times, `mysql_stmt_execute()` closes any open cursor before opening a new one.

Return Values

Zero if execution was successful. Non-zero if an error occurred.

Errors

- `CR_COMMANDS_OUT_OF_SYNC`
Commands were executed in an improper order.
- `CR_OUT_OF_MEMORY`
Out of memory.
- `CR_SERVER_GONE_ERROR`
The MySQL server has gone away.
- `CR_SERVER_LOST`
The connection to the server was lost during the query.
- `CR_UNKNOWN_ERROR`
An unknown error occurred.

Example

The following example demonstrates how to create and populate a table using `mysql_stmt_init()`, `mysql_stmt_prepare()`, `mysql_stmt_param_count()`, `mysql_stmt_bind_param()`, `mysql_stmt_execute()`, and `mysql_stmt_affected_rows()`. The `mysql` variable is assumed to be a valid connection handle.

```
#define STRING_SIZE 50

#define DROP_SAMPLE_TABLE "DROP TABLE IF EXISTS test_table"
#define CREATE_SAMPLE_TABLE "CREATE TABLE test_table(coll INT,\
                                         col2 VARCHAR(40),\
                                         col3 SMALLINT,\
                                         col4 TIMESTAMP)"

#define INSERT_SAMPLE "INSERT INTO \
test_table(coll,col2,col3) \
VALUES(?,?,?)"

MYSQL_STMT      *stmt;
MYSQL_BIND      bind[3];
my_ulonglong    affected_rows;

is_null= 0;      /* reset */

/* Execute the INSERT statement - 2*/
if (mysql_stmt_execute(stmt))
{
    fprintf(stderr, " mysql_stmt_execute, 2 failed\n");
    fprintf(stderr, " %s\n", mysql_stmt_error(stmt));
    exit(0);
}

/* Get the total rows affected */
affected_rows= mysql_stmt_affected_rows(stmt);
fprintf(stdout, " total affected rows(insert 2): %lu\n",
        (unsigned long) affected_rows);

if (affected_rows != 1) /* validate affected rows */
{
    fprintf(stderr, " invalid affected rows by MySQL\n");
    exit(0);
}

/* Close the statement */
if (mysql_stmt_close(stmt))
{
    fprintf(stderr, " failed while closing the statement\n");
    fprintf(stderr, " %s\n", mysql_stmt_error(stmt));
    exit(0);
}

```

Note: For complete examples on the use of prepared statement functions, refer to the file [tests/mysql_client_test.c](#). This file can be obtained from a MySQL source distribution or from the BitKeeper source repository.

24.2.7.11. `mysql_stmt_fetch()`

```
int mysql_stmt_fetch(MYSQL_STMT *stmt)
```

Description

`mysql_stmt_fetch()` returns the next row in the result set. It can be called only while the result set exists; that is, after a call to `mysql_stmt_execute()` that creates a result set or after `mysql_stmt_store_result()`, which is called after `mysql_stmt_execute()` to buffer the entire result set.

`mysql_stmt_fetch()` returns row data using the buffers bound by `mysql_stmt_bind_result()`. It returns the data in those buffers for all the columns in the current row set and the lengths are returned to the `length` pointer.

All columns must be bound by the application before calling `mysql_stmt_fetch()`.

If a fetched data value is a `NULL` value, the `*is_null` value of the corresponding `MYSQL_BIND` structure contains `TRUE` (1). Otherwise, the data and its length are returned in the `*buffer` and `*length` elements based on the buffer type specified by the application. Each numeric and temporal type has a fixed length, as listed in the following table. The length of the string types depends on the length of the actual data value, as indicated by `data_length`.

Type	Length
<code>MYSQL_TYPE_TINY</code>	1
<code>MYSQL_TYPE_SHORT</code>	2

<code>MYSQL_TYPE_LONG</code>	4
<code>MYSQL_TYPE_LONGLONG</code>	8
<code>MYSQL_TYPE_FLOAT</code>	4
<code>MYSQL_TYPE_DOUBLE</code>	8
<code>MYSQL_TYPE_TIME</code>	<code>sizeof(MYSQL_TIME)</code>
<code>MYSQL_TYPE_DATE</code>	<code>sizeof(MYSQL_TIME)</code>
<code>MYSQL_TYPE_DATETIME</code>	<code>sizeof(MYSQL_TIME)</code>
<code>MYSQL_TYPE_STRING</code>	<code>data length</code>
<code>MYSQL_TYPE_BLOB</code>	<code>data length</code>

Return Values

Return Value	Description
0	Successful, the data has been fetched to application data buffers.
1	Error occurred. Error code and message can be obtained by calling <code>mysql_stmt_errno()</code> and <code>mysql_stmt_error()</code> .
<code>MYSQL_NO_DATA</code>	No more rows/data exists
<code>MYSQL_DATA_TRUNCATED</code>	Data truncation occurred

`MYSQL_DATA_TRUNCATED` is returned when truncation reporting is enabled. (Reporting is enabled by default, but can be controlled with `mysql_options()`.) To determine which parameters were truncated when this value is returned, check the `error` members of the `MYSQL_BIND` parameter structures.

Errors

- `CR_COMMANDS_OUT_OF_SYNC`

Commands were executed in an improper order.
- `CR_OUT_OF_MEMORY`

Out of memory.
- `CR_SERVER_GONE_ERROR`

The MySQL server has gone away.
- `CR_SERVER_LOST`

The connection to the server was lost during the query.
- `CR_UNKNOWN_ERROR`

An unknown error occurred.
- `CR_UNSUPPORTED_PARAM_TYPE`

The buffer type is `MYSQL_TYPE_DATE`, `MYSQL_TYPE_TIME`, `MYSQL_TYPE_DATETIME`, or `MYSQL_TYPE_TIMESTAMP`, but the data type is not `DATE`, `TIME`, `DATETIME`, or `TIMESTAMP`.

- All other unsupported conversion errors are returned from `mysql_stmt_bind_result()`.

Example

The following example demonstrates how to fetch data from a table using `mysql_stmt_result_metadata()`, `mysql_stmt_bind_result()`, and `mysql_stmt_fetch()`. (This example expects to retrieve the two rows inserted by the example shown in [Section 24.2.7.10](#), “`mysql_stmt_execute()`”.) The `mysql` variable is assumed to be a valid connection handle.

```
#define STRING_SIZE 50

#define SELECT_SAMPLE "SELECT col1, col2, col3, col4 \
                      FROM test_table"

    exit(0);
}

/* Free the prepared result metadata */
mysql_free_result(prepare_meta_result);

/* Close the statement */
if (mysql_stmt_close(stmt))
{
    fprintf(stderr, " failed while closing the statement\n");
    fprintf(stderr, " %s\n", mysql_stmt_error(stmt));
    exit(0);
}

```

24.2.7.12. `mysql_stmt_fetch_column()`

```
int mysql_stmt_fetch_column(MYSQL_STMT *stmt, MYSQL_BIND *bind, unsigned int column, unsigned long offset)
```

Description

Fetch one column from the current result set row. `bind` provides the buffer where data should be placed. It should be set up the same way as for `mysql_stmt_bind_result()`. `column` indicates which column to fetch. The first column is numbered 0. `offset` is the offset within the data value at which to begin retrieving data. This can be used for fetching the data value in pieces. The beginning of the value is offset 0.

Return Values

Zero if the value was fetched successfully. Non-zero if an error occurred.

Errors

- `CR_INVALID_PARAMETER_NO`
Invalid column number.
- `CR_NO_DATA`
The end of the result set has already been reached.

24.2.7.13. `mysql_stmt_field_count()`

```
unsigned int mysql_stmt_field_count(MYSQL_STMT *stmt)
```

Description

Returns the number of columns for the most recent statement for the statement handler. This value is zero for statements such as `INSERT` or `DELETE` that do not produce result sets.

`mysql_stmt_field_count()` can be called after you have prepared a statement by invoking `mysql_stmt_prepare()`.

Return Values

An unsigned integer representing the number of columns in a result set.

Errors

None.

24.2.7.14. `mysql_stmt_free_result()`

```
my_bool mysql_stmt_free_result(MYSQL_STMT *stmt)
```

Description

Releases memory associated with the result set produced by execution of the prepared statement. If there is a cursor open for the statement, `mysql_stmt_free_result()` closes it.

Return Values

Zero if the result set was freed successfully. Non-zero if an error occurred.

Errors

24.2.7.15. `mysql_stmt_init()`

```
MYSQL_STMT *mysql_stmt_init(MYSQL *mysql)
```

Description

Create a `MYSQL_STMT` handle. The handle should be freed with `mysql_stmt_close(MYSQL_STMT *)`.

Return values

A pointer to a `MYSQL_STMT` structure in case of success. `NULL` if out of memory.

Errors

- `CR_OUT_OF_MEMORY`

Out of memory.

24.2.7.16. `mysql_stmt_insert_id()`

```
my_ulonglong mysql_stmt_insert_id(MYSQL_STMT *stmt)
```

Description

Returns the value generated for an `AUTO_INCREMENT` column by the prepared `INSERT` or `UPDATE` statement. Use this function after you have executed a prepared `INSERT` statement on a table which contains an `AUTO_INCREMENT` field.

See [Section 24.2.3.36](#), “`mysql_insert_id()`”, for more information.

Return Values

Value for `AUTO_INCREMENT` column which was automatically generated or explicitly set during execution of prepared statement, or value generated by `LAST_INSERT_ID(expr)` function. Return value is undefined if statement does not set `AUTO_INCREMENT` value.

Errors

None.

24.2.7.17. `mysql_stmt_num_rows()`

```
my_ulonglong mysql_stmt_num_rows(MYSQL_STMT *stmt)
```

Description

Returns the number of rows in the result set.

The use of `mysql_stmt_num_rows()` depends on whether you used `mysql_stmt_store_result()` to buffer the entire result set in the statement handle.

If you use `mysql_stmt_store_result()`, `mysql_stmt_num_rows()` may be called immediately.

`mysql_stmt_num_rows()` is intended for use with statements that return a result set, such as `SELECT`. For statements such as `INSERT`, `UPDATE`, or `DELETE`, the number of affected rows can be obtained with `mysql_stmt_affected_rows()`.

Return Values

The number of rows in the result set.

Errors

None.

24.2.7.18. `mysql_stmt_param_count()`

```
unsigned long mysql_stmt_param_count(MYSQL_STMT *stmt)
```

Description

Returns the number of parameter markers present in the prepared statement.

Return Values

An unsigned long integer representing the number of parameters in a statement.

Errors

None.

Example

For the usage of `mysql_stmt_param_count()`, refer to the Example from [Section 24.2.7.10](#), “`mysql_stmt_execute()`”.

24.2.7.19. `mysql_stmt_param_metadata()`

```
MYSQL_RES *mysql_stmt_param_metadata(MYSQL_STMT *stmt)
```

This function currently does nothing.

Description

Return Values

Errors

24.2.7.20. `mysql_stmt_prepare()`

```
int mysql_stmt_prepare(MYSQL_STMT *stmt, const char *query, unsigned long length)
```

Description

Given the statement handle returned by `mysql_stmt_init()`, prepares the SQL statement pointed to by the string `query` and returns a status value. The string length should be given by the `length` argument. The string must consist of a single SQL statement. You should not add a terminating semicolon (`;`) or `\g` to the statement.

The application can include one or more parameter markers in the SQL statement by embedding question mark (`?`) characters into the SQL string at the appropriate positions.

The markers are legal only in certain places in SQL statements. For example, they are allowed in the `VALUES()` list of an `INSERT` statement (to specify column values for a row), or in a comparison with a column in a `WHERE` clause to specify a comparison value. However, they are not allowed for identifiers (such as table or column names), or to specify both operands of a binary operator such as the `=` equal sign. The latter restriction is necessary because it would be impossible to determine the parameter type. In general, parameters are legal only in Data Manipulation Language (DML) statements, and not in Data Definition Language (DDL) statements.

The parameter markers must be bound to application variables using `mysql_stmt_bind_param()` before executing the statement.

Return Values

Zero if the statement was prepared successfully. Non-zero if an error occurred.

Errors

- `CR_COMMANDS_OUT_OF_SYNC`
Commands were executed in an improper order.
- `CR_OUT_OF_MEMORY`
Out of memory.
- `CR_SERVER_GONE_ERROR`
The MySQL server has gone away.

- `CR_SERVER_LOST`

The connection to the server was lost during the query

- `CR_UNKNOWN_ERROR`

An unknown error occurred.

If the prepare operation was unsuccessful (that is, `mysql_stmt_prepare()` returns non-zero), the error message can be obtained by calling `mysql_stmt_error()`.

Example

For the usage of `mysql_stmt_prepare()`, refer to the Example from [Section 24.2.7.10](#), “`mysql_stmt_execute()`”.

24.2.7.21. `mysql_stmt_reset()`

```
my_bool mysql_stmt_reset(MYSQL_STMT *stmt)
```

Description

Reset the prepared statement on the client and server to state after prepare. This is mainly used to reset data sent with `mysql_stmt_send_long_data()`. Any open cursor for the statement is closed.

To re-prepare the statement with another query, use `mysql_stmt_prepare()`.

Return Values

Zero if the statement was reset successfully. Non-zero if an error occurred.

Errors

- `CR_COMMANDS_OUT_OF_SYNC`

Commands were executed in an improper order.

- `CR_SERVER_GONE_ERROR`

The MySQL server has gone away.

- `CR_SERVER_LOST`

The connection to the server was lost during the query

- `CR_UNKNOWN_ERROR`

An unknown error occurred.

24.2.7.22. `mysql_stmt_result_metadata()`

```
MYSQL_RES *mysql_stmt_result_metadata(MYSQL_STMT *stmt)
```

Description

If a statement passed to `mysql_stmt_prepare()` is one that produces a result set,

`mysql_stmt_result_metadata()` returns the result set metadata in the form of a pointer to a `MYSQL_RES` structure that can be used to process the meta information such as total number of fields and individual field information. This result set pointer can be passed as an argument to any of the field-based API functions that process result set metadata, such as:

- `mysql_num_fields()`
- `mysql_fetch_field()`
- `mysql_fetch_field_direct()`
- `mysql_fetch_fields()`
- `mysql_field_count()`
- `mysql_field_seek()`
- `mysql_field_tell()`
- `mysql_free_result()`

The result set structure should be freed when you are done with it, which you can do by passing it to `mysql_free_result()`. This is similar to the way you free a result set obtained from a call to `mysql_store_result()`.

The result set returned by `mysql_stmt_result_metadata()` contains only metadata. It does not contain any row results. The rows are obtained by using the statement handle with `mysql_stmt_fetch()`.

Return Values

A `MYSQL_RES` result structure. `NULL` if no meta information exists for the prepared query.

Errors

- `CR_OUT_OF_MEMORY`
Out of memory.
- `CR_UNKNOWN_ERROR`
An unknown error occurred.

Example

For the usage of `mysql_stmt_result_metadata()`, refer to the Example from [Section 24.2.7.11](#), “`mysql_stmt_fetch()`”.

24.2.7.23. `mysql_stmt_row_seek()`

```
MYSQL_ROW_OFFSET mysql_stmt_row_seek(MYSQL_STMT *stmt,  
MYSQL_ROW_OFFSET offset)
```

Description

Sets the row cursor to an arbitrary row in a statement result set. The `offset` value is a row offset that

should be a value returned from `mysql_stmt_row_tell()` or from `mysql_stmt_row_seek()`. This value is not a row number; if you want to seek to a row within a result set by number, use `mysql_stmt_data_seek()` instead.

This function requires that the result set structure contains the entire result of the query, so `mysql_stmt_row_seek()` may be used only in conjunction with `mysql_stmt_store_result()`.

Return Values

The previous value of the row cursor. This value may be passed to a subsequent call to `mysql_stmt_row_seek()`.

Errors

None.

24.2.7.24. `mysql_stmt_row_tell()`

```
MYSQL_ROW_OFFSET mysql_stmt_row_tell(MYSQL_STMT *stmt)
```

Description

Returns the current position of the row cursor for the last `mysql_stmt_fetch()`. This value can be used as an argument to `mysql_stmt_row_seek()`.

You should use `mysql_stmt_row_tell()` only after `mysql_stmt_store_result()`.

Return Values

The current offset of the row cursor.

Errors

None.

24.2.7.25. `mysql_stmt_send_long_data()`

```
my_bool mysql_stmt_send_long_data(MYSQL_STMT *stmt, unsigned int parameter_number, const char *data, unsigned long length)
```

Description

Allows an application to send parameter data to the server in pieces (or “chunks”). This function can be called multiple times to send the parts of a character or binary data value for a column, which must be one of the `TEXT` or `BLOB` data types.

`parameter_number` indicates which parameter to associate the data with. Parameters are numbered beginning with 0. `data` is a pointer to a buffer containing data to be sent, and `length` indicates the number of bytes in the buffer.

Note: The next `mysql_stmt_execute()` call ignores the bind buffer for all parameters that have been used with `mysql_stmt_send_long_data()` since last `mysql_stmt_execute()` or `mysql_stmt_reset()`.

If you want to reset/forget the sent data, you can do it with `mysql_stmt_reset()`. See [Section 24.2.7.21](#), “`mysql_stmt_reset()`”.

Return Values

Zero if the data is sent successfully to server. Non-zero if an error occurred.

Errors

- [CR_COMMANDS_OUT_OF_SYNC](#)
Commands were executed in an improper order.
- [CR_SERVER_GONE_ERROR](#)
The MySQL server has gone away.
- [CR_OUT_OF_MEMORY](#)
Out of memory.
- [CR_UNKNOWN_ERROR](#)
An unknown error occurred.

Example

The following example demonstrates how to send the data for a `TEXT` column in chunks. It inserts the data value `'MySQL - The most popular Open Source database'` into the `text_column` column. The `mysql` variable is assumed to be a valid connection handle.

```
#define INSERT_QUERY "INSERT INTO \
                    test_long_data(text_column) VALUES(?)"

MYSQL_BIND bind[1];
long        length;

stmt = mysql_stmt_init(mysql);
if (!stmt)
{
    fprintf(stderr, " mysql_stmt_init(), out of memory\n");
    exit(0);
}
if (mysql_stmt_prepare(stmt, INSERT_QUERY, strlen(INSERT_QUERY)))
{
    fprintf(stderr, "\n mysql_stmt_prepare(), INSERT failed");
    fprintf(stderr, "\n %s", mysql_stmt_error(stmt));
    exit(0);
}
memset(bind, 0, sizeof(bind));
bind[0].buffer_type= MYSQL_TYPE_STRING;
bind[0].length= &length;
bind[0].is_null= 0;

/* Bind the buffers */
if (mysql_stmt_bind_param(stmt, bind))
{
    fprintf(stderr, "\n param bind failed");
    fprintf(stderr, "\n %s", mysql_stmt_error(stmt));
    exit(0);
}

/* Supply data in chunks to server */
if (!mysql_stmt_send_long_data(stmt,0,"MySQL",5))
{
    fprintf(stderr, "\n send_long_data failed");
    fprintf(stderr, "\n %s", mysql_stmt_error(stmt));
    exit(0);
}

/* Supply the next piece of data */
if (mysql_stmt_send_long_data(stmt,0,
    " - The most popular Open Source database",40))
{
```

```

fprintf(stderr, "\n send_long_data failed");
fprintf(stderr, "\n %s", mysql_stmt_error(stmt));
exit(0);
}

/* Now, execute the query */
if (mysql_stmt_execute(stmt))
{
    fprintf(stderr, "\n mysql_stmt_execute failed");
    fprintf(stderr, "\n %s", mysql_stmt_error(stmt));
    exit(0);
}

```

24.2.7.26. `mysql_stmt_sqlstate()`

```
const char *mysql_stmt_sqlstate(MYSQL_STMT *stmt)
```

Description

For the statement specified by `stmt`, `mysql_stmt_sqlstate()` returns a null-terminated string containing the SQLSTATE error code for the most recently invoked prepared statement API function that can succeed or fail. The error code consists of five characters. "00000" means "no error." The values are specified by ANSI SQL and ODBC. For a list of possible values, see [Appendix B, Error Codes and Messages](#).

Note that not all MySQL errors are yet mapped to SQLSTATE codes. The value "HY000" (general error) is used for unmapped errors.

Return Values

A null-terminated character string containing the SQLSTATE error code.

24.2.7.27. `mysql_stmt_store_result()`

```
int mysql_stmt_store_result(MYSQL_STMT *stmt)
```

Description

You must call `mysql_stmt_store_result()` for every statement that successfully produces a result set (`SELECT`, `SHOW`, `DESCRIBE`, `EXPLAIN`), and only if you want to buffer the complete result set by the client, so that the subsequent `mysql_stmt_fetch()` call returns buffered data.

It is unnecessary to call `mysql_stmt_store_result()` for other statements, but if you do, it does not harm or cause any notable performance problem. You can detect whether the statement produced a result set by checking if `mysql_stmt_result_metadata()` returns `NULL`. For more information, refer to [Section 24.2.7.22](#), "`mysql_stmt_result_metadata()`".

Note: MySQL doesn't by default calculate `MYSQL_FIELD->max_length` for all columns in `mysql_stmt_store_result()` because calculating this would slow down `mysql_stmt_store_result()` considerably and most applications doesn't need `max_length`. If you want `max_length` to be updated, you can call `mysql_stmt_attr_set(MYSQL_STMT, STMT_ATTR_UPDATE_MAX_LENGTH, &flag)` to enable this. See [Section 24.2.7.3](#), "`mysql_stmt_attr_set()`".

Return Values

Zero if the results are buffered successfully. Non-zero if an error occurred.

Errors

- `CR_COMMANDS_OUT_OF_SYNC`
Commands were executed in an improper order.
- `CR_OUT_OF_MEMORY`
Out of memory.
- `CR_SERVER_GONE_ERROR`
The MySQL server has gone away.
- `CR_SERVER_LOST`
The connection to the server was lost during the query.
- `CR_UNKNOWN_ERROR`
An unknown error occurred.

24.2.8. C API Prepared statement problems

Here follows a list of the currently known problems with prepared statements:

- `TIME`, `TIMESTAMP`, and `DATETIME` do not support parts of seconds (for example from `DATE_FORMAT()`).
- When converting an integer to string, `ZEROFILL` is honored with prepared statements in some cases where the MySQL server doesn't print the leading zeros. (For example, with `MIN(number-with-zerofill)`).
- When converting a floating point number to a string in the client, the rightmost digits of the converted value may differ slightly from those of the original value.
- *Prepared statements do not use the Query Cache, even in cases where a query does not contain any placeholders. See Section 5.14.1, “How the Query Cache Operates”.*
- Prepared statements do not support multi-statements (that is, multiple statements within a single string separated by ‘;’ characters). This also means that prepared statements cannot invoke stored procedures that return result sets, because prepared statements do not support multiple result sets.

24.2.9. C API Handling of Multiple Statement Execution

MySQL 5.1 supports the execution of multiple statements specified in a single query string. To use this capability with a given connection, you must specify the `CLIENT_MULTI_STATEMENTS` option in the `flags` parameter to `mysql_real_connect()` when opening the connection. You can also set this for an existing connection by calling `mysql_set_server_option(MYSQL_OPTION_MULTI_STATEMENTS_ON)`.

By default, `mysql_query()` and `mysql_real_query()` return only the first query status and the subsequent queries status can be processed using `mysql_more_results()` and `mysql_next_result()`.

If you enable multiple-statement support, you should process the results from `mysql_query()` and `mysql_real_query()` within a loop that checks for more results. This is true even for statements

such as `DROP TABLE` that return a result but not a result set. Failure to process the result this way may result in a dropped connection to the server.

```

/* Connect to server with option CLIENT_MULTI_STATEMENTS */
mysql_real_connect(..., CLIENT_MULTI_STATEMENTS);

/* Now execute multiple queries */
mysql_query(mysql, "DROP TABLE IF EXISTS test_table;\
CREATE TABLE test_table(id INT);\
INSERT INTO test_table VALUES(10);\
UPDATE test_table SET id=20 WHERE id=10;\
SELECT * FROM test_table;\
DROP TABLE test_table");

do
{
    /* Process all results */
    ...
    printf("total affected rows: %lld", mysql_affected_rows(mysql));
    ...
    if (!(result= mysql_store_result(mysql)))
    {
        printf(stderr, "Got fatal error processing query\n");
        exit(1);
    }
    process_result_set(result); /* client function */
    mysql_free_result(result);
} while (!mysql_next_result(mysql));

```

The multiple-statement capability can be used with `mysql_query()` or `mysql_real_query()`. It cannot be used with the prepared statement interface. Prepared statement handles are defined to work only with strings that contain a single statement.

24.2.10. C API Handling of Date and Time Values

The binary protocol allows you to send and receive date and time values (`DATE`, `TIME`, `DATETIME`, and `TIMESTAMP`), using the `MYSQL_TIME` structure. The members of this structure are described in [Section 24.2.5, “C API Prepared Statement Data types”](#).

To send temporal data values, create a prepared statement using `mysql_stmt_prepare()`. Then, before calling `mysql_stmt_execute()` to execute the statement, use the following procedure to set up each temporal parameter:

1. In the `MYSQL_BIND` structure associated with the data value, set the `buffer_type` member to the type that indicates what kind of temporal value you're sending. For `DATE`, `TIME`, `DATETIME`, or `TIMESTAMP` values, set `buffer_type` to `MYSQL_TYPE_DATE`, `MYSQL_TYPE_TIME`, `MYSQL_TYPE_DATETIME`, or `MYSQL_TYPE_TIMESTAMP`, respectively.
2. Set the `buffer` member of the `MYSQL_BIND` structure to the address of the `MYSQL_TIME` structure in which you pass the temporal value.
3. Fill in the members of the `MYSQL_TIME` structure that are appropriate for the type of temporal value to be passed.

Use `mysql_stmt_bind_param()` to bind the parameter data to the statement. Then you can call `mysql_stmt_execute()`.

To retrieve temporal values, the procedure is similar, except that you set the `buffer_type` member to the type of value you expect to receive, and the `buffer` member to the address of a `MYSQL_TIME` structure into which the returned value should be placed. Use `mysql_bind_results()` to bind the buffers to the statement after calling `mysql_stmt_execute()` and before fetching the results.

Here is a simple example that inserts `DATE`, `TIME`, and `TIMESTAMP` data. The `mysql` variable is assumed to be a valid connection handle.

```

MYSQL_TIME  ts;
MYSQL_BIND  bind[3];
MYSQL_STMT  *stmt;

strmov(query, "INSERT INTO test_table(date_field, time_field, \
          timestamp_field) VALUES(?,?,?");

stmt = mysql_stmt_init(mysql);
if (!stmt)
{
    fprintf(stderr, " mysql_stmt_init(), out of memory\n");
    exit(0);
}
if (mysql_stmt_prepare(mysql, query, strlen(query))
{
    fprintf(stderr, "\n mysql_stmt_prepare(), INSERT failed");
    fprintf(stderr, "\n %s", mysql_stmt_error(stmt));
    exit(0);
}

/* set up input buffers for all 3 parameters */
bind[0].buffer_type= MYSQL_TYPE_DATE;
bind[0].buffer= (char *)&ts;
bind[0].is_null= 0;
bind[0].length= 0;
...
bind[1]= bind[2]= bind[0];
...

mysql_stmt_bind_param(stmt, bind);

/* supply the data to be sent in the ts structure */
ts.year= 2002;
ts.month= 02;
ts.day= 03;

ts.hour= 10;
ts.minute= 45;
ts.second= 20;

mysql_stmt_execute(stmt);
..

```

24.2.11. C API Threaded Function Descriptions

You need to use the following functions when you want to create a threaded client. See [Section 24.2.15, “How to Make a Threaded Client”](#).

24.2.11.1. `my_init()`

```
void my_init(void)
```

Description

This function needs to be called once in the program before calling any MySQL function. This initializes some global variables that MySQL needs. If you are using a thread-safe client library, this also calls `mysql_thread_init()` for this thread.

This is automatically called by `mysql_init()`, `mysql_library_init()`, `mysql_server_init()` and `mysql_connect()`.

Return Values

None.

24.2.11.2. `mysql_thread_init()`

```
my_bool mysql_thread_init(void)
```

Description

This function needs to be called for each created thread to initialize thread-specific variables.

This is automatically called by `my_init()` and `mysql_connect()`.

Return Values

Zero if successful. Non-zero if an error occurred.

24.2.11.3. `mysql_thread_end()`

```
void mysql_thread_end(void)
```

Description

This function needs to be called before calling `pthread_exit()` to free memory allocated by `mysql_thread_init()`.

Note that this function *is not invoked automatically by the client library*. It must be called explicitly to avoid a memory leak.

Return Values

None.

24.2.11.4. `mysql_thread_safe()`

```
unsigned int mysql_thread_safe(void)
```

Description

This function indicates whether the client is compiled as thread-safe.

Return Values

1 if the client is thread-safe, 0 otherwise.

24.2.12. C API Embedded Server Function Descriptions

If you want to allow your application to be linked against the embedded MySQL server library, you must use the `mysql_server_init()` and `mysql_server_end()` functions. See [Section 24.1, “libmysqld, the Embedded MySQL Server Library”](#).

However, to provide improved memory management, even programs that are linked with `-lmysqlclient` rather than `-lmysqld` should include calls to begin and end use of the library. The `mysql_library_init()` and `mysql_library_end()` functions can be used to do this. These actually are `#define` symbols that make them equivalent to `mysql_server_init()` and `mysql_server_end()`, but the names more clearly indicate that they should be called when beginning and ending use of a MySQL C API library no matter whether the application uses `libmysqlclient` or `libmysqld`. For more information, see [Section 24.2.2, “C API Function Overview”](#).

24.2.12.1. `mysql_server_init()`

```
int mysql_server_init(int argc, char **argv, char **groups)
```

Description

This function **must** be called once in the program using the embedded server before calling any other MySQL function. It starts the server and initializes any subsystems (`mysys`, `InnoDB`, and so forth) that the server uses. If this function is not called, the next call to `mysql_init()` executes `mysql_server_init()`.

In a non-multi-threaded environment, the call to `mysql_server_init()` may be omitted, because `mysql_init()` will invoke it automatically as necessary. However, a race condition is possible if `mysql_server_init()` is invoked by `mysql_init()` in a multi-threaded environment: `mysql_server_init()` is not thread-safe, so it should be called prior to any other client library call.

If you are using the `DEBUG` package that comes with MySQL, you should call `mysql_server_init()` after you have called `my_init()`.

The `argc` and `argv` arguments are analogous to the arguments to `main()`. The first element of `argv` is ignored (it typically contains the program name). For convenience, `argc` may be 0 (zero) if there are no command-line arguments for the server. `mysql_server_init()` makes a copy of the arguments so it's safe to destroy `argv` or `groups` after the call.

If you want to connect to an external server without starting the embedded server, you have to specify a negative value for `argc`.

The `NULL`-terminated list of strings in `groups` selects which groups in the option files are active. See [Section 4.3.2, "Using Option Files"](#). For convenience, `groups` may be `NULL`, in which case the `[server]` and `[embedded]` groups are active.

Example

```
#include <mysql.h>
#include <stdlib.h>

static char *server_args[] = {
    "this_program", /* this string is not used */
    "--datadir=.",
    "--key_buffer_size=32M"
};

static char *server_groups[] = {
    "embedded",
    "server",
    "this_program_SERVER",
    (char *)NULL
};

int main(void) {
    if (mysql_server_init(sizeof(server_args) / sizeof(char *),
                        server_args, server_groups))
        exit(1);

    /* Use any MySQL API functions here */

    mysql_server_end();

    return EXIT_SUCCESS;
}
```

Return Values

0 if okay, 1 if an error occurred.

24.2.12.2. `mysql_server_end()`

```
void mysql_server_end(void)
```

Description

This function **must** be called once in the program after all other MySQL functions. It shuts down the embedded server.

Return Values

None.

24.2.13. Common Questions and Problems When Using the C API

24.2.13.1. Why `mysql_store_result()` Sometimes Returns `NULL` After `mysql_query()` Returns Success

It is possible for `mysql_store_result()` to return `NULL` following a successful call to `mysql_query()`. When this happens, it means one of the following conditions occurred:

- There was a `malloc()` failure (for example, if the result set was too large).
- The data couldn't be read (an error occurred on the connection).
- The query returned no data (for example, it was an `INSERT`, `UPDATE`, or `DELETE`).

You can always check whether the statement should have produced a non-empty result by calling `mysql_field_count()`. If `mysql_field_count()` returns zero, the result is empty and the last query was a statement that does not return values (for example, an `INSERT` or a `DELETE`). If `mysql_field_count()` returns a non-zero value, the statement should have produced a non-empty result. See the description of the `mysql_field_count()` function for an example.

You can test for an error by calling `mysql_error()` or `mysql_errno()`.

24.2.13.2. What Results You Can Get from a Query

In addition to the result set returned by a query, you can also get the following information:

- `mysql_affected_rows()` returns the number of rows affected by the last query when doing an `INSERT`, `UPDATE`, or `DELETE`.

For a fast re-create, use `TRUNCATE TABLE`.

- `mysql_num_rows()` returns the number of rows in a result set. With `mysql_store_result()`, `mysql_num_rows()` may be called as soon as `mysql_store_result()` returns. With `mysql_use_result()`, `mysql_num_rows()` may be called only after you have fetched all the rows with `mysql_fetch_row()`.
- `mysql_insert_id()` returns the ID generated by the last query that inserted a row into a table with an `AUTO_INCREMENT` index. See [Section 24.2.3.36](#), “`mysql_insert_id()`”.
- Some queries (`LOAD DATA INFILE ...`, `INSERT INTO ... SELECT ...`, `UPDATE`) return additional information. The result is returned by `mysql_info()`. See the description for `mysql_info()` for the format of the string that it returns. `mysql_info()` returns a `NULL` pointer if there is no additional information.

24.2.13.3. How to Get the Unique ID for the Last Inserted Row

If you insert a record into a table that contains an `AUTO_INCREMENT` column, you can obtain the value stored into that column by calling the `mysql_insert_id()` function.

You can check from your C applications whether a value was stored in an `AUTO_INCREMENT` column by executing the following code (which assumes that you've checked that the statement succeeded). It determines whether the query was an `INSERT` with an `AUTO_INCREMENT` index:

```
if ((result = mysql_store_result(&mysql)) == 0 &&
    mysql_field_count(&mysql) == 0 &&
    mysql_insert_id(&mysql) != 0)
{
    used_id = mysql_insert_id(&mysql);
}
```

For more information, see [Section 24.2.3.36, “mysql_insert_id\(\)”](#).

When a new `AUTO_INCREMENT` value has been generated, you can also obtain it by executing a `SELECT LAST_INSERT_ID()` statement with `mysql_query()` and retrieving the value from the result set returned by the statement.

For `LAST_INSERT_ID()`, the most recently generated ID is maintained in the server on a per-connection basis. It is not changed by another client. It is not even changed if you update another `AUTO_INCREMENT` column with a non-magic value (that is, a value that is not `NULL` and not `0`).

If you want to use the ID that was generated for one table and insert it into a second table, you can use SQL statements like this:

```
INSERT INTO foo (auto,text)
VALUES(NULL,'text');          # generate ID by inserting NULL
INSERT INTO foo2 (id,text)
VALUES(LAST_INSERT_ID(),'text'); # use ID in second table
```

Note that `mysql_insert_id()` returns the value stored into an `AUTO_INCREMENT` column, whether that value is automatically generated by storing `NULL` or `0` or was specified as an explicit value. `LAST_INSERT_ID()` returns only automatically generated `AUTO_INCREMENT` values. If you store an explicit value other than `NULL` or `0`, it does not affect the value returned by `LAST_INSERT_ID()`.

24.2.13.4. Problems Linking with the C API

When linking with the C API, the following errors may occur on some systems:

```
gcc -g -o client test.o -L/usr/local/lib/mysql \
    -lmysqlclient -lsocket -lnsl

Undefined      first referenced
 symbol        in file
floor          /usr/local/lib/mysql/libmysqlclient.a(password.o)
ld: fatal: Symbol referencing errors. No output written to client
```

If this happens on your system, you must include the math library by adding `-lm` to the end of the compile/link line.

24.2.14. Building Client Programs

If you compile MySQL clients that you've written yourself or that you obtain from a third-party, they must be linked using the `-lmysqlclient -lz` options in the link command. You may also need to specify a `-L` option to tell the linker where to find the library. For example, if the library is installed in `/usr/local/mysql/lib`, use `-L/usr/local/mysql/lib -lmysqlclient -lz` in the link

command.

For clients that use MySQL header files, you may need to specify an `-I` option when you compile them (for example, `-I/usr/local/mysql/include`), so that the compiler can find the header files.

To make it simpler to compile MySQL programs on Unix, we have provided the `mysql_config` script for you. See [Section 24.9.2, “mysql_config — Get Compile Options for Compiling Clients”](#).

You can use it to compile a MySQL client as follows:

```
CFG=/usr/local/mysql/bin/mysql_config
sh -c "gcc -o progname ` $CFG --cflags ` progname.c ` $CFG --libs `"
```

The `sh -c` is needed to get the shell not to treat the output from `mysql_config` as one word.

24.2.15. How to Make a Threaded Client

The client library is almost thread-safe. The biggest problem is that the subroutines in `net.c` that read from sockets are not interrupt safe. This was done with the thought that you might want to have your own alarm that can break a long read to a server. If you install interrupt handlers for the `SIGPIPE` interrupt, the socket handling should be thread-safe.

To avoid aborting the program when a connection terminates, MySQL blocks `SIGPIPE` on the first call to `mysql_server_init()`, `mysql_init()`, or `mysql_connect()`. If you want to use your own `SIGPIPE` handler, you should first call `mysql_server_init()` and then install your handler.

In the older binaries we distribute on our Web site (<http://www.mysql.com/>), the client libraries are not normally compiled with the thread-safe option (the Windows binaries are by default compiled to be thread-safe). Newer binary distributions should have both a normal and a thread-safe client library.

To get a threaded client where you can interrupt the client from other threads and set timeouts when talking with the MySQL server, you should use the `-lmysys`, `-lmystrings`, and `-ldbug` libraries and the `net_serv.o` code that the server uses.

If you don't need interrupts or timeouts, you can just compile a thread-safe client library (`mysqlclient_r`) and use this. See [Section 24.2, “MySQL C API”](#). In this case, you don't have to worry about the `net_serv.o` object file or the other MySQL libraries.

When using a threaded client and you want to use timeouts and interrupts, you can make great use of the routines in the `thr_alarm.c` file. If you are using routines from the `mysys` library, the only thing you must remember is to call `my_init()` first! See [Section 24.2.11, “C API Threaded Function Descriptions”](#).

All functions except `mysql_real_connect()` are by default thread-safe. The following notes describe how to compile a thread-safe client library and use it in a thread-safe manner. (The notes below for `mysql_real_connect()` actually apply to `mysql_connect()` as well, but because `mysql_connect()` is deprecated, you should be using `mysql_real_connect()` anyway.)

To make `mysql_real_connect()` thread-safe, you must recompile the client library with this command:

```
shell> ./configure --enable-thread-safe-client
```

This creates a thread-safe client library `libmysqlclient_r`. (Assuming that your OS has a thread-safe `gethostbyname_r()` function.) This library is thread-safe per connection. You can let two threads share the same connection with the following caveats:

- Two threads can't send a query to the MySQL server at the same time on the same connection. In

particular, you have to ensure that between a `mysql_query()` and `mysql_store_result()` no other thread is using the same connection.

- Many threads can access different result sets that are retrieved with `mysql_store_result()`.
- If you use `mysql_use_result`, you have to ensure that no other thread is using the same connection until the result set is closed. However, it really is best for threaded clients that share the same connection to use `mysql_store_result()`.
- If you want to use multiple threads on the same connection, you must have a mutex lock around your `mysql_query()` and `mysql_store_result()` call combination. Once `mysql_store_result()` is ready, the lock can be released and other threads may query the same connection.
- If you program with POSIX threads, you can use `pthread_mutex_lock()` and `pthread_mutex_unlock()` to establish and release a mutex lock.

You need to know the following if you have a thread that is calling MySQL functions which did not create the connection to the MySQL database:

When you call `mysql_init()` or `mysql_connect()`, MySQL creates a thread-specific variable for the thread that is used by the debug library (among other things).

If you call a MySQL function, before the thread has called `mysql_init()` or `mysql_connect()`, the thread does not have the necessary thread-specific variables in place and you are likely to end up with a core dump sooner or later.

To get things to work smoothly you have to do the following:

1. Call `my_init()` at the start of your program if it calls any other MySQL function before calling `mysql_real_connect()`.
2. Call `mysql_thread_init()` in the thread handler before calling any MySQL function.
3. In the thread, call `mysql_thread_end()` before calling `pthread_exit()`. This frees the memory used by MySQL thread-specific variables.

You may get some errors because of undefined symbols when linking your client with `libmysqlclient_r`. In most cases this is because you haven't included the thread libraries on the link/compile line.

24.3. MySQL PHP API

PHP is a server-side, HTML-embedded scripting language that may be used to create dynamic Web pages. It is available for most operating systems and Web servers, and can access most common databases, including MySQL. PHP may be run as a separate program or compiled as a module for use with the Apache Web server.

PHP actually provides two different MySQL API extensions:

- `mysql`: Available for PHP versions 4 and 5, this extension is intended for use with MySQL versions prior to MySQL 4.1. This extension does not support the improved authentication protocol used in MySQL 5.1, nor does it support prepared statements or multiple statements. If you wish to use this extension with MySQL 5.1, you will likely want to configure the MySQL server to use the `--old-passwords` option (see [Section A.2.3, "Client does not support authentic-](#)

ation protocol”). This extension is documented on the PHP Web site at <http://php.net/mysql>.

- `mysqli` - Stands for “MySQL, Improved”; this extension is available only in PHP 5. It is intended for use with MySQL 4.1.1 and later. This extension fully supports the authentication protocol used in MySQL 5.1, as well as the Prepared Statements and Multiple Statements APIs. In addition, this extension provides an advanced, object-oriented programming interface. You can read the documentation for the `mysqli` extension at <http://php.net/mysqli>. A helpful article can be found at <http://www.zend.com/php5/articles/php5-mysqli.php>.

If you're experiencing problems with enabling both the `mysql` and the `mysqli` extension when building PHP on Linux yourself, see [Section 24.3.2, “Enabling Both `mysql` and `mysqli` in PHP”](#).

The PHP distribution and documentation are available from the [PHP Web site](http://www.php.net/) [http://www.php.net/]. MySQL provides the `mysql` and `mysqli` extensions for the Windows operating system on <http://dev.mysql.com/downloads/connector/php/>. You can find information why you should preferably use the extensions provided by MySQL on that page.

24.3.1. Common Problems with MySQL and PHP

- `Error: Maximum Execution Time Exceeded`: This is a PHP limit; go into the `php.ini` file and set the maximum execution time up from 30 seconds to something higher, as needed. It is also not a bad idea to double the RAM allowed per script to 16MB instead of 8MB.
- `Fatal error: Call to unsupported or undefined function mysql_connect() in ...`: This means that your PHP version isn't compiled with MySQL support. You can either compile a dynamic MySQL module and load it into PHP or recompile PHP with built-in MySQL support. This process is described in detail in the PHP manual.
- `Error: Undefined reference to 'uncompress'`: This means that the client library is compiled with support for a compressed client/server protocol. The fix is to add `-lz` last when linking with `-lmysqlclient`.
- `Error: Client does not support authentication protocol`: This is most often encountered when trying to use the older `mysql` extension with MySQL 4.1.1 and later. Possible solutions are: downgrade to MySQL 4.0; switch to PHP 5 and the newer `mysqli` extension; or configure the MySQL server with `--old-passwords`. (See [Section A.2.3, “Client does not support authentication protocol”](#), for more information.)

Those with PHP4 legacy code can make use of a compatibility layer for the old and new MySQL libraries, such as this one: <http://www.coggeshall.org/oss/mysql2i>.

24.3.2. Enabling Both `mysql` and `mysqli` in PHP

If you're experiencing problems with enabling both the `mysql` and the `mysqli` extension when building PHP on Linux yourself, you should try the following procedure.

1. Configure PHP like this:

```
./configure --with-mysqli=/usr/bin/mysql_config --with-mysql=/usr
```

2. Edit the `Makefile` and search for a line that starts with `EXTRA_LIBS`. It might look like this (all on one line):

```
EXTRA_LIBS = -lcrypt -lcrypt -lmysqlclient -lz -lresolv -lm -ldl -lnsl
```

```
-lxml2 -lz -lm -lxml2 -lz -lm -lmysqlclient -lz -lcrypt -lnsl -lm
-lxml2 -lz -lm -lcrypt -lxml2 -lz -lm -lcrypt
```

Remove all duplicates, so that the line looks like this (all on one line):

```
EXTRA_LIBS = -lcrypt -lcrypt -lmysqlclient -lz -lresolv -lm -ldl -lnsl
-lxml2
```

3. Build and install PHP:

```
make
make install
```

24.4. MySQL Perl API

The Perl `DBI` module provides a generic interface for database access. You can write a DBI script that works with many different database engines without change. To use DBI, you must install the `DBI` module, as well as a DataBase Driver (DBD) module for each type of server you want to access. For MySQL, this driver is the `DBD::mysql` module.

Perl DBI is the recommended Perl interface. It replaces an older interface called `mysqlperl`, which should be considered obsolete.

Installation instructions for Perl DBI support are given in [Section 2.14, “Perl Installation Notes”](#).

DBI information is available at the command line, online, or in printed form:

- Once you have the `DBI` and `DBD::mysql` modules installed, you can get information about them at the command line with the `perldoc` command:

```
shell> perldoc DBI
shell> perldoc DBI::FAQ
shell> perldoc DBD::mysql
```

You can also use `pod2man`, `pod2html`, and so forth to translate this information into other formats.

- For online information about Perl DBI, visit the DBI Web site, <http://dbi.perl.org/>. That site hosts a general DBI mailing list. MySQL AB hosts a list specifically about `DBD::mysql`; see [Section 1.7.1, “MySQL Mailing Lists”](#).
- For printed information, the official DBI book is *Programming the Perl DBI* (Alligator Descartes and Tim Bunce, O'Reilly & Associates, 2000). Information about the book is available at the DBI Web site, <http://dbi.perl.org/>.

For information that focuses specifically on using DBI with MySQL, see *MySQL and Perl for the Web* (Paul DuBois, New Riders, 2001). This book's Web site is <http://www.kitebird.com/mysql-perl/>.

24.5. MySQL C++ API

`MySQL++` is a MySQL API for C++. Warren Young has taken over this project. More information can be found at <http://www.mysql.com/products/mysql++/>.

24.6. MySQL Python API

`MySQLdb` provides MySQL support for Python, compliant with the Python DB API version 2.0. It can be found at <http://sourceforge.net/projects/mysql-python/>.

24.7. MySQL Tcl API

`MySQLtcl` is a simple API for accessing a MySQL database server from the Tcl programming language. It can be found at <http://www.xdobry.de/mysqltcl/>.

24.8. MySQL Eiffel Wrapper

Eiffel MySQL is an interface to the MySQL database server using the Eiffel programming language, written by Michael Ravits. It can be found at <http://efsa.sourceforge.net/archive/ravits/mysql.htm>.

24.9. MySQL Program Development Utilities

This section describes some utilities that you may find useful when developing MySQL programs.

- `msql2mysql`

A shell script that converts `mSQL` programs to MySQL. It doesn't handle every case, but it gives a good start when converting.

- `mysql_config`

A shell script that produces the option values needed when compiling MySQL programs.

24.9.1. `msql2mysql` — Convert mSQL Programs for Use with MySQL

Initially, the MySQL C API was developed to be very similar to that for the `mSQL` database system. Because of this, `mSQL` programs often can be converted relatively easily for use with MySQL by changing the names of the C API functions.

The `msql2mysql` utility performs the conversion of `mSQL` C API function calls to their MySQL equivalents. `msql2mysql` converts the input file in place, so make a copy of the original before converting it. For example, use `msql2mysql` like this:

```
shell> cp client-prog.c client-prog.c.orig
shell> msql2mysql client-prog.c
client-prog.c converted
```

Then examine `client-prog.c` and make any post-conversion revisions that may be necessary.

`msql2mysql` uses the `replace` utility to make the function name substitutions. See [Section 8.18](#), “`replace` — A String-Replacement Utility”.

24.9.2. `mysql_config` — Get Compile Options for Compiling Clients

`mysql_config` provides you with useful information for compiling your MySQL client and connect-

ing it to MySQL.

`mysql_config` supports the following options:

- `--cflags`
Compiler flags to find include files and critical compiler flags and defines used when compiling the `libmysqlclient` library.
- `--include`
Compiler options to find MySQL include files. (Note that normally you would use `--cflags` instead of this option.)
- `--libmysqld-libs`, `--embedded`
Libraries and options required to link with the MySQL embedded server.
- `--libs`
Libraries and options required to link with the MySQL client library.
- `--libs_r`
Libraries and options required to link with the thread-safe MySQL client library.
- `--port`
The default TCP/IP port number, defined when configuring MySQL.
- `--socket`
The default Unix socket file, defined when configuring MySQL.
- `--version`
Version number for the MySQL distribution.

If you invoke `mysql_config` with no options, it displays a list of all options that it supports, and their values:

```
shell> mysql_config
Usage: /usr/local/mysql/bin/mysql_config [options]
Options:
--cflags          [-I/usr/local/mysql/include/mysql -mcpu=pentiumpro]
--include        [-I/usr/local/mysql/include/mysql]
--libs           [-L/usr/local/mysql/lib/mysql -lmysqlclient -lz
                 -lcrypt -lnsl -lm -L/usr/lib -lssl -lcrypto]
--libs_r        [-L/usr/local/mysql/lib/mysql -lmysqlclient_r
                 -lpthread -lz -lcrypt -lnsl -lm -lpthread]
--socket         [/tmp/mysql.sock]
--port           [3306]
--version        [4.0.16]
--libmysqld-libs [-L/usr/local/mysql/lib/mysql -lmysqld -lpthread -lz
                 -lcrypt -lnsl -lm -lpthread -lrt]
```

You can use `mysql_config` within a command line to include the value that it displays for a particular option. For example, to compile a MySQL client program, use `mysql_config` as follows:

```
shell> CFG=/usr/local/mysql/bin/mysql_config
shell> sh -c "gcc -o progname ` $CFG --cflags ` progname.c ` $CFG --libs `"
```

When you use `mysql_config` this way, be sure to invoke it within backtick (``) characters. That tells the shell to execute it and substitute its output into the surrounding command.

Chapter 25. Connectors

This chapter describes MySQL Connectors, drivers that provide connectivity to the MySQL server for client programs. There are currently five MySQL Connectors:

- Connector/ODBC provides driver support for connecting to a MySQL server using the Open Database Connectivity (ODBC) API. Support is available for ODBC connectivity from Windows, Unix and Mac OS X platforms.
- Connector/NET enables developers to create .NET applications that use data stored in a MySQL database. Connector/NET implement a fully-functional ADO.NET interface and provides support for use with ADO.NET aware tools. Applications that want to use Connector/NET can be written in any of the supported .NET languages.
- Connector/J provides driver support for connecting to MySQL from a Java application using the standard Java Database Connectivity (JDBC) API.
- Connector/MXJ is a tool that enables easy deployment and management of MySQL server and database through your Java application.
- Connector/PHP is a Windows-only connector for PHP that provides the `mysql` and `mysqli` extensions for use with MySQL 5.0.18 and later.

For information on connecting to a MySQL server using other languages and interfaces than those detailed above, including Perl, Python and PHP for other platforms and environments, please refer to the [Chapter 24, APIs and Libraries](#) chapter.

25.1. MySQL Connector/ODBC

The MySQL Connector/ODBC is the name for the family of MySQL ODBC drivers (also called MyODBC drivers) that provide access to a MySQL database using the industry standard Open Database Connectivity (ODBC) API. This reference covers Connector/ODBC 3.51, a version of the API that provides ODBC 3.5x compliant access to a MySQL database.

The manual for versions of MyODBC older than 3.51 can be located in the corresponding binary or source distribution.

For more information on the ODBC API standard and how to use it, refer to <http://www.microsoft.com/data/>.

The application development part of this reference assumes a good working knowledge of C, general DBMS knowledge, and finally, but not least, familiarity with MySQL. For more information about MySQL functionality and its syntax, refer to <http://dev.mysql.com/doc/>.

Typically, you need to install MyODBC only on Windows machines. For Unix and Mac OS X you can use the native MySQL network or named pipe to communicate with your MySQL database. You may need MyODBC for Unix or Mac OS X if you have an application that requires an ODBC interface to communicate with database.. Applications that require ODBC to communicate with MySQL include ColdFusion, Microsoft Office, and Filemaker Pro.

If you want to install the MyODBC connector on a Unix host, then you must also install an ODBC manager.

If you have questions that are not answered in this document, please send a mail message to [<myodbc@lists.mysql.com>](mailto:myodbc@lists.mysql.com).

25.1.1. Introduction to Connector/ODBC

ODBC (Open Database Connectivity) provides a way for client programs to access a wide range of databases or data sources. ODBC is a standardized API that allows connections to SQL database servers. It was developed according to the specifications of the SQL Access Group and defines a set of function calls, error codes, and data types that can be used to develop database-independent applications. ODBC usually is used when database independence or simultaneous access to different data sources is required.

For more information about ODBC, refer to <http://www.microsoft.com/data/>.

25.1.1.1. MyODBC Versions

There are currently two version of MyODBC available:

- MyODBC 5.0, currently in beta status, has been designed to extend the functionality of the MyODBC 3.51 driver and incorporate full support for the functionality in the MySQL 5.0 server release, including stored procedures and views. Applications using MyODBC 3.51 will be compatible with MyODBC 5.0, while being able to take advantage of the new features. Features and functionality of the MyODBC 5.0 driver are not currently included in this guide.
- MyODBC 3.51 is the current release of the 32-bit ODBC driver, also known as the MySQL ODBC 3.51 driver. This version is enhanced compared to the older MyODBC 2.50 driver. It has support for ODBC 3.5x specification level 1 (complete core API + level 2 features) in order to continue to provide all functionality of ODBC for accessing MySQL.
- MyODBC 2.50 is the previous version of the 32-bit ODBC driver from MySQL AB that is based on ODBC 2.50 specification level 0 (with level 1 and 2 features). Information about the MyODBC 2.50 driver is included in this guide for the purposes of comparison only.

Note: From this section onward, the primary focus of this guide is the MyODBC 3.51 driver. More information about the MyODBC 2.50 driver in the documentation included in the installation packages for that version. If there is a specific issue (error or known problem) that only affects the 2.50 version, it may be included here for reference.

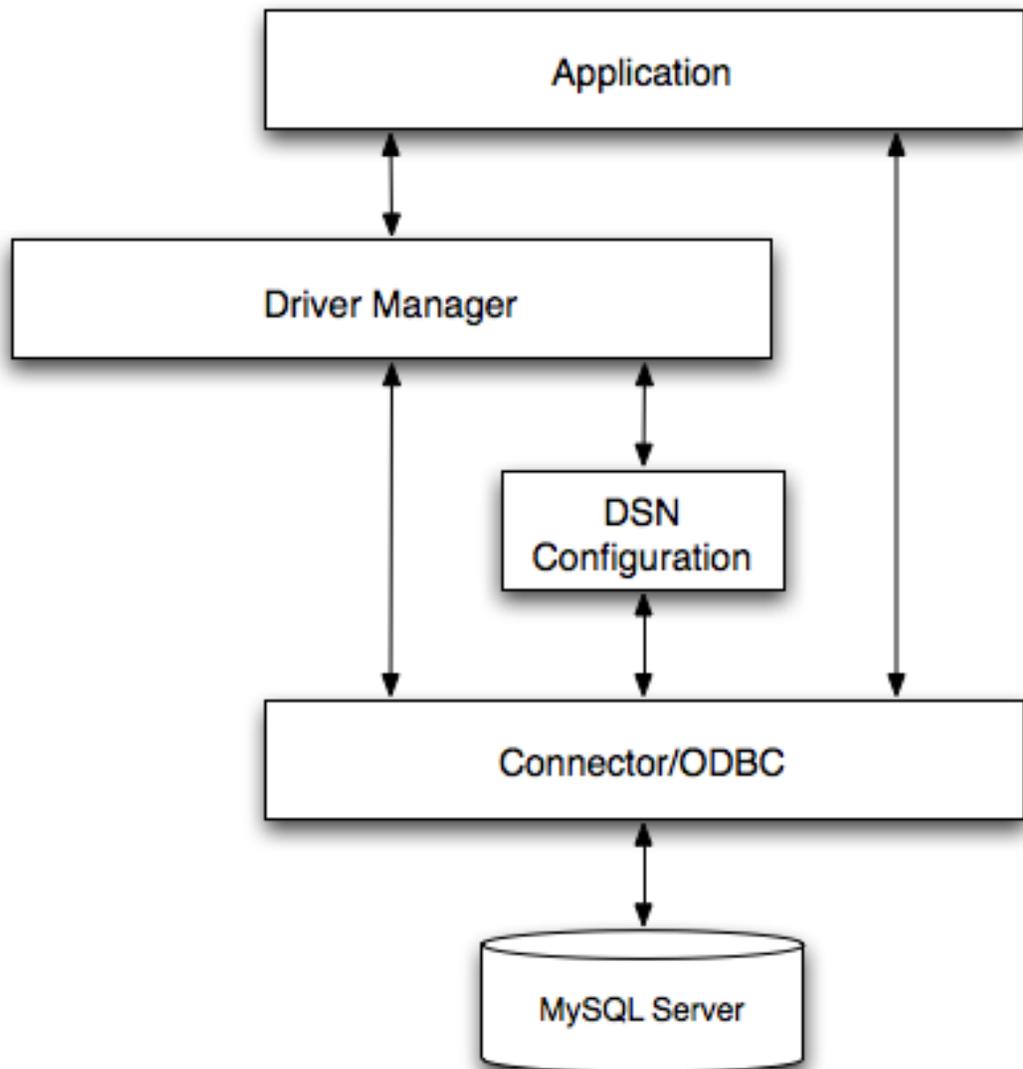

25.1.1.2. General Information About ODBC and MyODBC

Open Database Connectivity (ODBC) is a widely accepted application-programming interface (API) for database access. It is based on the Call-Level Interface (CLI) specifications from X/Open and ISO/IEC for database APIs and uses Structured Query Language (SQL) as its database access language.

A survey of ODBC functions supported by MyODBC is given at [Section 25.1.5.1, “MyODBC API Reference”](#). For general information about ODBC, see <http://www.microsoft.com/data/>.

25.1.1.2.1. MyODBC Architecture

The MyODBC architecture is based on five components, as shown in the following diagram:

- **Application:**

The Application uses the ODBC API to access the data from the MySQL server. The ODBC API in turn uses the communicates with the Driver Manager. The Application communicates with the Driver Manager using the standard ODBC calls. The Application does not care where the data is stored, how it is stored, or even how the system is configured to access the data. It needs to know only the Data Source Name (DSN).

A number of tasks are common to all applications, no matter how they use ODBC. These tasks are:

- Selecting the MySQL server and connecting to it
- Submitting SQL statements for execution
- Retrieving results (if any)
- Processing errors

- Committing or rolling back the transaction enclosing the SQL statement
- Disconnecting from the MySQL server

Because most data access work is done with SQL, the primary tasks for applications that use ODBC are submitting SQL statements and retrieving any results generated by those statements.

- **Driver manager:**

The Driver Manager is a library that manages communication between application and driver or drivers. It performs the following tasks:

- Resolves Data Source Names (DSN). The DSN is a configuration string that identifies a given database driver, database, database host and optionally authentication information that enables an ODBC application to connect to a database using a standardized reference.

Because the database connectivity information is identified by the DSN, any ODBC compliant application can connect to the data source using the same DSN reference. This eliminates the need to separately configure each application that needs access to a given database; instead you instruct the application to use a pre-configured DSN.

- Loading and unloading of the driver required to access a specific database as defined within the DSN. For example, if you have configured a DSN that connects to a MySQL database then the driver manager will load the MyODBC driver to enable the ODBC API to communicate with the MySQL host.
- Processes ODBC function calls or passes them to the driver for processing.

- **MyODBC Driver:**

The MyODBC driver is a library that implements the functions supported by the ODBC API. It processes ODBC function calls, submits SQL requests to MySQL server, and returns results back to the application. If necessary, the driver modifies an application's request so that the request conforms to syntax supported by MySQL.

- **DSN Configuration:**

The ODBC configuration file stores the driver and database information required to connect to the server. It is used by the Driver Manager to determine which driver to be loaded according to the definition in the DSN. The driver uses this to read connection parameters based on the DSN specified. For more information, [Section 25.1.3, “MyODBC Configuration”](#).

- **MySQL Server:**

The MySQL database where the information is stored. The database is used as the source of the data (during queries) and the destination for data (during inserts and updates).

25.1.1.2.2. ODBC Driver Managers

An ODBC Driver Manager is a library that manages communication between the ODBC-aware application and any drivers. Its main functionality includes:

- Resolving Data Source Names (DSN).
- Driver loading and unloading.

- Processing ODBC function calls or passing them to the driver.

Both Windows and Mac OS X include ODBC driver managers with the operating system. Most ODBC Driver Manager implementations also include an administration application that makes the configuration of DSN and drivers easier. Examples and information on these managers, including Unix ODBC driver managers are listed below:

- Microsoft Windows ODBC Driver Manager (`odbc32.dll`), <http://www.microsoft.com/data/>.
- Mac OS X includes `ODBC Administrator`, a GUI application that provides a simpler configuration mechanism for the Unix iODBC Driver Manager. You can configure DSN and driver information either through ODBC Administrator or through the iODBC configuration files. This also means that you can test ODBC Administrator configurations using the `iodbctest` command. <http://www.apple.com>.
- `unixODBC` Driver Manager for Unix (`libodbc.so`). See <http://www.unixodbc.org>, for more information. The `unixODBC` Driver Manager includes the MyODBC driver 3.51 in the installation package, starting with version `unixODBC 2.1.2`.
- `iODBC` ODBC Driver Manager for Unix (`libiodbc.so`), see <http://www.iodbc.org>, for more information.

25.1.2. Installing Connector/ODBC

You can install the MyODBC drivers using two different methods, a binary installation and a source installation. The binary installation is the easiest and most straightforward method of installation. Using the source installation methods should only be necessary on platforms where a binary installation package is not available, or in situations where you want to customize or modify the installation process or MyODBC drivers before installation.

25.1.2.1. Where to Get MyODBC

MySQL AB distributes all its products under the General Public License (GPL). You can get a copy of the latest version of MyODBC binaries and sources from the MySQL AB Web site <http://dev.mysql.com/downloads/>.

For more information about MyODBC, visit <http://www.mysql.com/products/myodbc/>.

For more information about licensing, visit <http://www.mysql.com/company/legal/licensing/>.

25.1.2.2. Supported Platforms

MyODBC can be used on all major platforms supported by MySQL. You can install it on:

- Windows 95, 98, Me, NT, 2000, XP, and 2003
- All Unix-like Operating Systems, including: AIX, Amiga, BSDI, DEC, FreeBSD, HP-UX 10/11, Linux, NetBSD, OpenBSD, OS/2, SGI Irix, Solaris, SunOS, SCO OpenServer, SCO UnixWare, Tru64 Unix
- Mac OS X and Mac OS X Server

If a binary distribution is not available for a particular platform, see [Section 25.1.2.4, “Installing MyOD-](#)

[BC from a source distribution](#)”, to build the driver from the original source code. You can contribute the binaries you create to MySQL by sending a mail message to [<myodbc@lists.mysql.com>](mailto:myodbc@lists.mysql.com), so that it becomes available for other users.

25.1.2.3. Installing MyODBC from a binary distribution

Using a binary distribution offers the most straightforward method for installing MyODBC. If you want more control over the driver, the installation location and or to customize elements of the driver you will need to build and install from the source. See the [Section 25.1.2.4, “Installing MyODBC from a source distribution”](#).

25.1.2.3.1. Installing MyODBC from a Binary Distribution on Windows

Before installing the MyODBC drivers on Windows you should ensure that your Microsoft Data Access Components (MDAC) are up to date. You can obtain the latest version from the [Microsoft Data Access and Storage](http://www.microsoft.com/data/) [http://www.microsoft.com/data/] website.

There are three available distribution types to use when installing for Windows. The contents in each case are identical, it is only the installation method which is different.

- Zipped installer consists of a Zipped package containing a standalone installation application. To install from this package, you must unzip the installer, and then run the installation application. See [Section 25.1.2.3.1.1, “Installing the Windows MyODBC Driver using an installer”](#) to complete the installation.
- MSI installer, an installation file that can be used with the installer included in Windows 2000, Windows XP and Windows Server 2003. See [Section 25.1.2.3.1.1, “Installing the Windows MyODBC Driver using an installer”](#) to complete the installation.
- Zipped DLL package, containing the DLL files that need must be manually installed. See [Section 25.1.2.3.1.2, “Installing the Windows MyODBC Driver using the Zipped DLL package”](#) to complete the installation.

25.1.2.3.1.1. Installing the Windows MyODBC Driver using an installer

The installer packages offer a very simple method for installing the MyODBC drivers. If you have downloaded the zipped installer then you must extract the installer application. The basic installation process is identical for both installers.

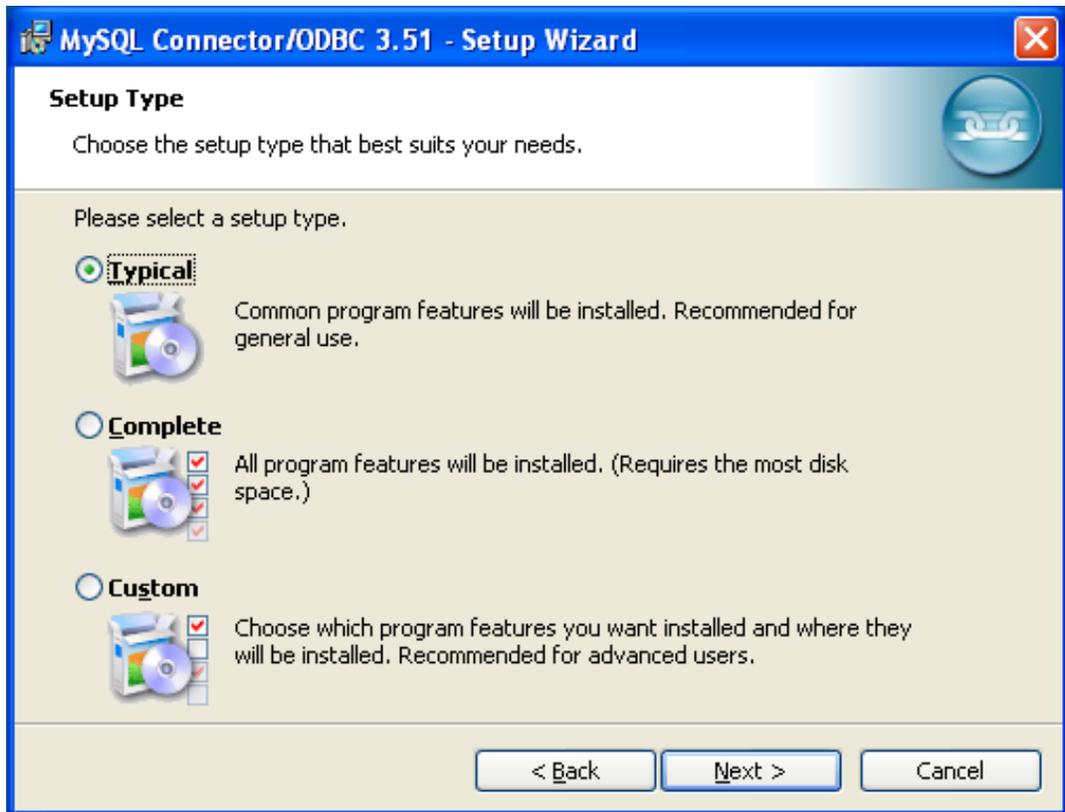

You should follow these steps to complete the installation:

1. Double click on the standalone installer that you extracted, or the MSI file you downloaded.
2. The MySQL Connector/ODBC 3.51 - Setup Wizard will start. Click the [Next](#) button to begin the installation process.

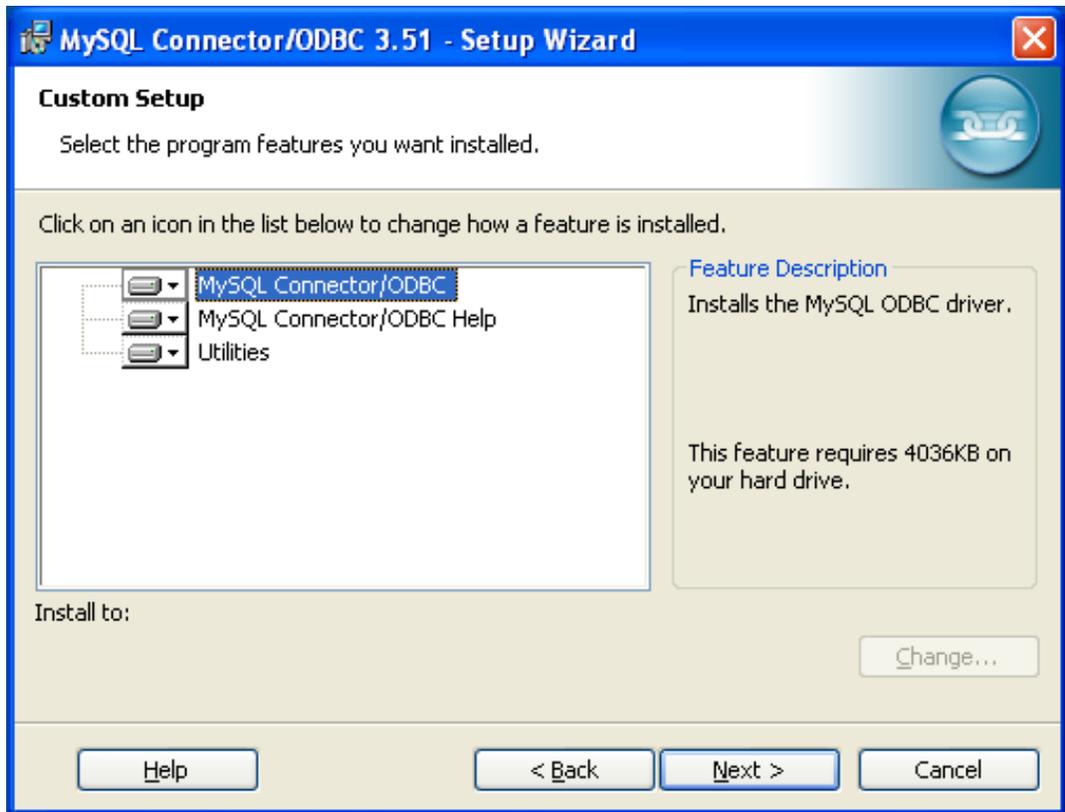

3. You will need to choose the installation type. The Typical installation provides the standard files you will need to connect to a MySQL database using ODBC. The Complete option installs all the available files, including debug and utility components. It is recommended you choose one of these two options to complete the installation. If choose one of these methods, click [Next](#) and then proceed to step 5.

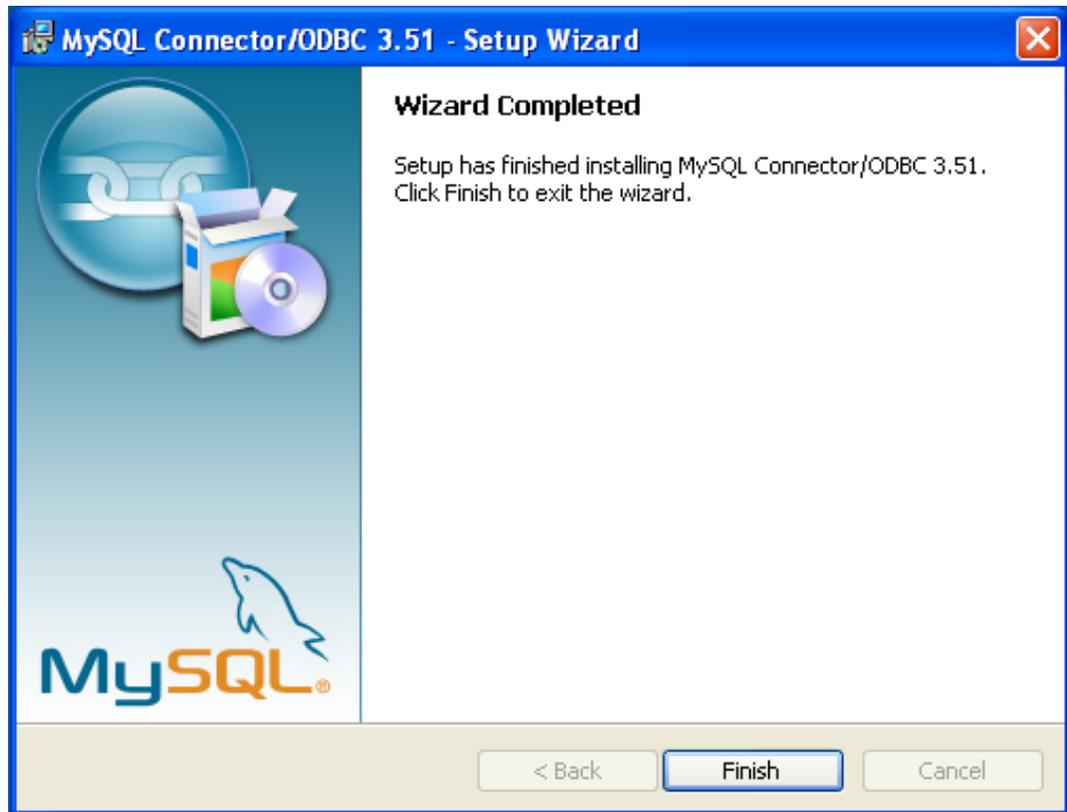

You may also choose a Custom installation, which enables you to select the individual components that you want to install. You have chosen this method, click [Next](#) and then proceed to step 4.

4. If you have chosen a custom installation, use the popups to select which components to install and then click [Next](#) to install the necessary files.

5. Once the files have copied to your machine, the installation is complete. Click **Finish** to exit the installer.

Now the installation is complete, you can continue to configure your ODBC connections using [Section 25.1.3, “MyODBC Configuration”](#).

25.1.2.3.1.2. Installing the Windows MyODBC Driver using the Zipped DLL package

If you have downloaded the Zipped DLL package then you must install the individual files required for MyODBC operation manually. Once you have unzipped the installation files, you can either perform this operation by hand, executing each statement individually, or you can use the included Batch file to perform an installation to the default locations.

To install using the Batch file:

1. Unzip the MyODBC Zipped DLL package.
2. Open a Command Prompt.
3. Change to the directory created when you unzipped the MyODBC Zipped DLL package.
4. Run `Install.bat`:

```
C:\> Install.bat
```

This will copy the necessary files into the default location, and then register the MyODBC driver with the Windows ODBC manager.

If you want to copy the files to an alternative location - for example, to run or test different versions of

the MyODBC driver on the same machine, then you must copy the files by hand. It is however not recommended to install these files in a non-standard location. To copy the files by hand to the default installation location use the following steps:

1. Unzip the MyODBC Zipped DLL package.
2. Open a Command Prompt.
3. Change to the directory created when you unzipped the MyODBC Zipped DLL package.
4. Copy the library files to a suitable directory. The default is to copy them into the default Windows system directory `\Windows\System32`:

```
C:\> copy lib\myodbc3s.dll \Windows\System32
C:\> copy lib\myodbc3s.lib \Windows\System32
C:\> copy lib\myodbc3.dll \Windows\System32
C:\> copy lib\myodbc3.lib \Windows\System32
```

5. Copy the MyODBC tools. These must be placed into a directory that is in the system `PATH`. The default is to install these into the Windows system directory `\Windows\System32`:

```
C:\> copy bin\myodbc3i.exe \Windows\System32
C:\> copy bin\myodbc3m.exe \Windows\System32
C:\> copy bin\myodbc3c.exe \Windows\System32
```

6. Optionally copy the help files. For these files to be accessible through the help system, they must be installed in the Windows system directory:

```
C:\> copy doc\*.hlp \Windows\System32
```

7. Finally, you must register the MyODBC driver with the ODBC manager:

```
C:\> myodbc3i -a -d -t"MySQL ODBC 3.51 Driver;\
DRIVER=myodbc3.dll;SETUP=myodbc3s.dll"
```

You must change the references to the DLL files and command location in the above statement if you have not installed these files into the default location.

25.1.2.3.1.3. Handling Installation Errors

On Windows, you may get the following error when trying to install the older MyODBC 2.50 driver:

```
An error occurred while copying C:\WINDOWS\SYSTEM\MFC30.DLL.
Restart Windows and try installing again (before running any
applications which use ODBC)
```

The reason for the error is that another application is currently using the ODBC system. Windows may not allow you to complete the installation. In most cases, you can continue by pressing `Ignore` to copy the rest of the MyODBC files and the final installation should still work. If it doesn't, the solution is to re-boot your computer in "safe mode." Choose safe mode by pressing `F8` just before your machine starts Windows during re-booting, install the MyODBC drivers, and re-boot to normal mode.

25.1.2.3.2. Installing MyODBC from a Binary Distribution on Unix

There are two methods available for installing MyODBC on Unix from a binary distribution. For most Unix environments you will need to use the tarball distribution. For Linux systems, there is also an RPM distribution available.

25.1.2.3.2.1. Installing MyODBC from a Binary Tarball Distribution

To install the driver from a tarball distribution (`.tar.gz` file), download the latest version of the driver for your operating system and follow these steps that demonstrate the process using the Linux version of the tarball:

```
shell> su root
shell> gunzip MyODBC-3.51.11-i686-pc-linux.tar.gz
shell> tar xvf MyODBC-3.51.11-i686-pc-linux.tar
shell> cd MyODBC-3.51.11-i686-pc-linux
```

Read the installation instructions in the `INSTALL-BINARY` file and execute these commands.

```
shell> cp libmyodbc* /usr/local/lib
shell> cp odbc.ini /usr/local/etc
shell> export ODBCINI=/usr/local/etc/odbc.ini
```

Then proceed on to [Section 25.1.3.4, “Configuring a MyODBC DSN on Unix”](#), to configure the DSN for MyODBC. For more information, refer to the `INSTALL-BINARY` file that comes with your distribution.

25.1.2.3.2.2. Installing MyODBC from an RPM Distribution

To install or upgrade MyODBC from an RPM distribution on Linux, simply download the RPM distribution of the latest version of MyODBC and follow the instructions below. Use `su root` to become `root`, then install the RPM file.

If you are installing for the first time:

```
shell> su root
shell> rpm -ivh MyODBC-3.51.12.i386.rpm
```

If the driver exists, upgrade it like this:

```
shell> su root
shell> rpm -Uvh MyODBC-3.51.12.i386.rpm
```

If there is any dependency error for MySQL client library, `libmysqlclient`, simply ignore it by supplying the `--nodeps` option, and then make sure the MySQL client shared library is in the path or set through `LD_LIBRARY_PATH`.

This installs the driver libraries and related documents to `/usr/local/lib` and `/usr/share/doc/MyODBC`, respectively. Proceed onto [Section 25.1.3.4, “Configuring a MyODBC DSN on Unix”](#).

To **uninstall** the driver, become `root` and execute an `rpm` command:

```
shell> su root
shell> rpm -e MyODBC
```

25.1.2.3.3. Installing MyODBC on Mac OS X

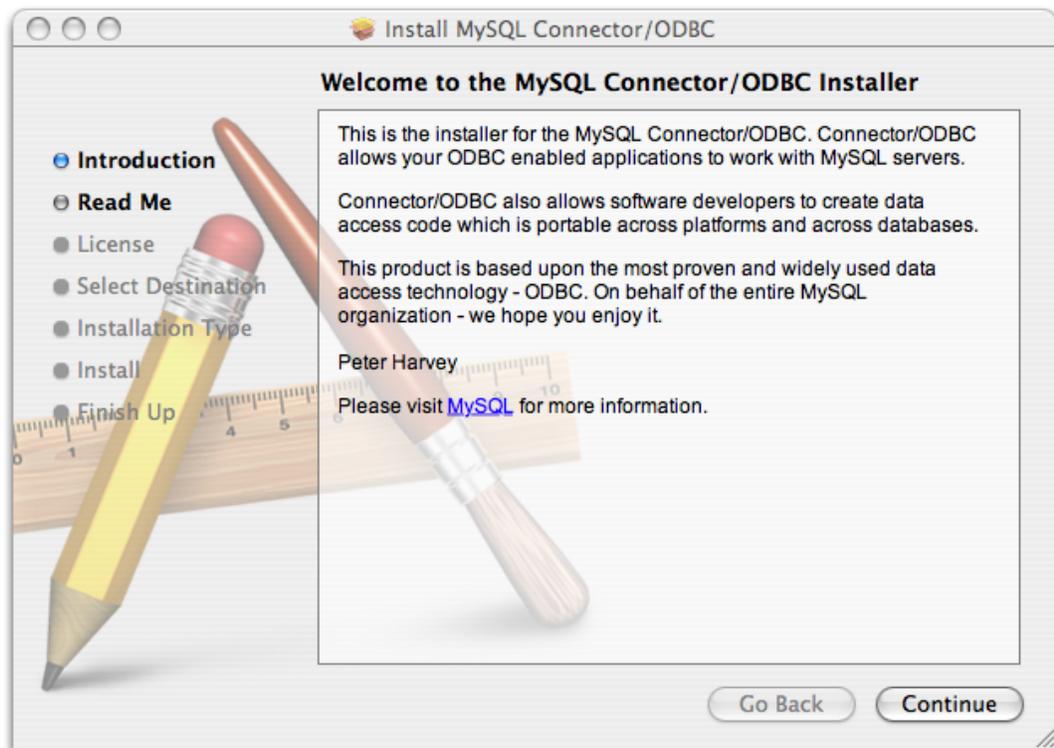

Mac OS X is based on the FreeBSD operating system, and you can normally use the MySQL network port for connecting to MySQL servers on other hosts. Installing the MyODBC driver enables you to connect to MySQL databases on any platform through the ODBC interface. You should only need to install the MyODBC driver when your application requires an ODBC interface. Applications that require or can use ODBC (and therefore the MyODBC driver) include ColdFusion, Filemaker Pro, 4th Dimension and many other applications.

Mac OS X includes its own ODBC manager, based on the [iODBC](#) manager. Mac OS X includes an administration tool that provides easier administration of ODBC drivers and configuration, updating the underlying [iODBC](#) configuration files.

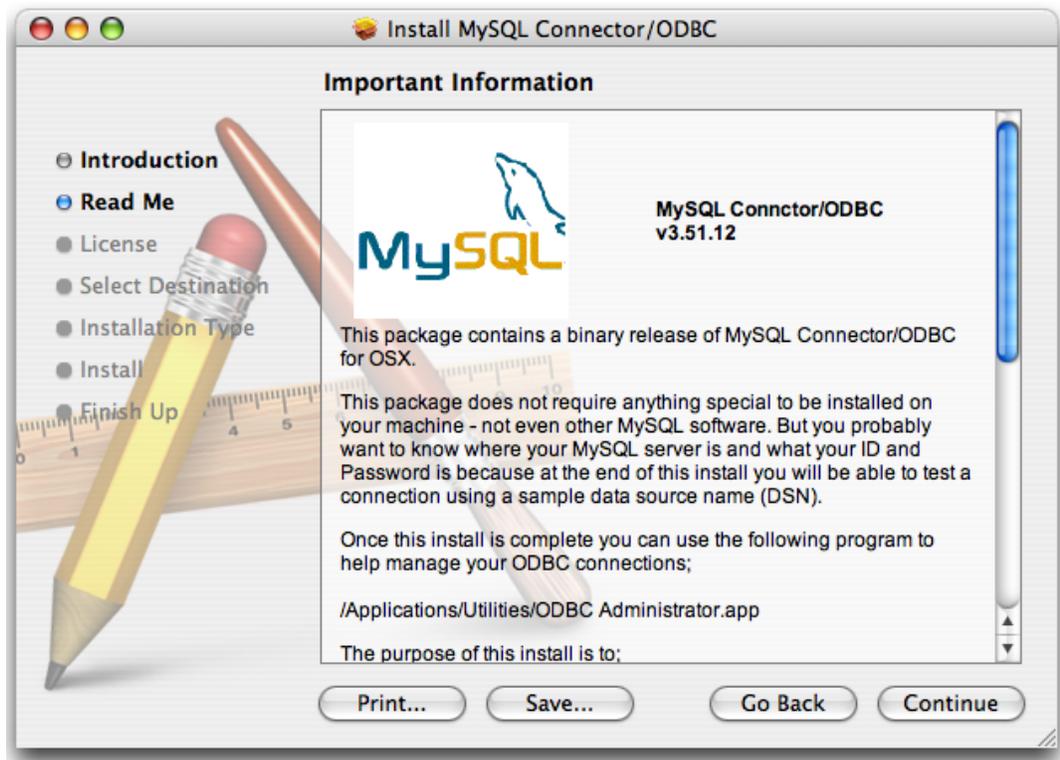

25.1.2.3.3.1. Installing the MyODBC Driver

You can install MyODBC on a Mac OS X or Mac OS X Server computer by using the binary distribution. The package is available as a compressed disk image ([.dmg](#)) file. To install MyODBC on your computer using this method, follow these steps:

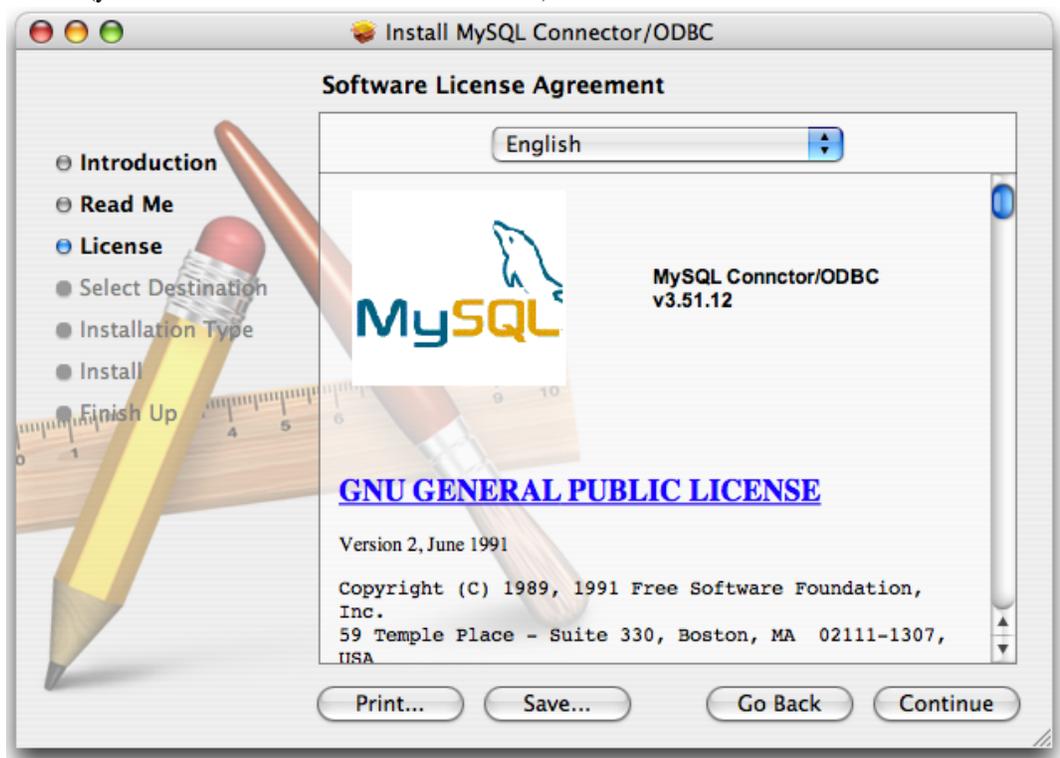

1. Download the file to your computer and double-click on the downloaded image file.
2. Within the disk image you will find an installer package (with the [.pkg](#) extension). Double click on this file to start the Mac OS X installer.
3. You will be presented with the installer welcome message. Click the [Continue](#) button to begin the installation process.

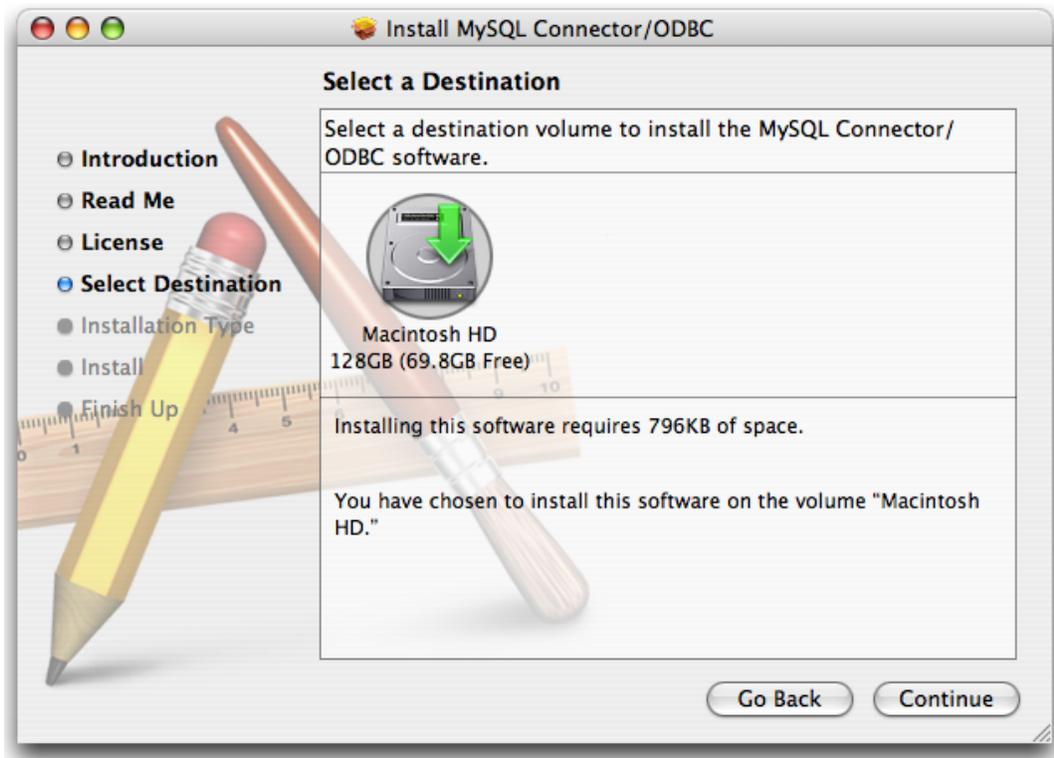

4. Please take the time to read the Important Information as it contains guidance on how to complete the installation process. Once you have read the notice and collected the necessary information, click [Continue](#).

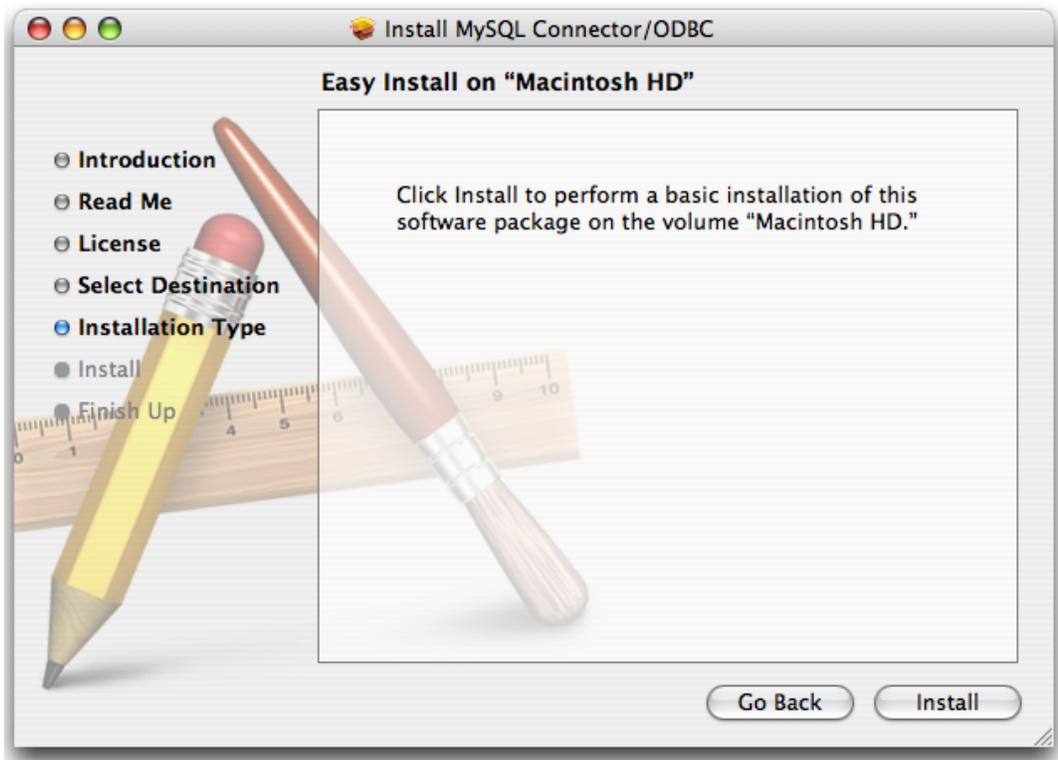

5. MyODBC drivers are made available under the GNU General Public License. Please read the license if you are not familiar with it before continuing installation. Click [Continue](#) to approve the license (you will be asked to confirm that decision) and continue the installation.

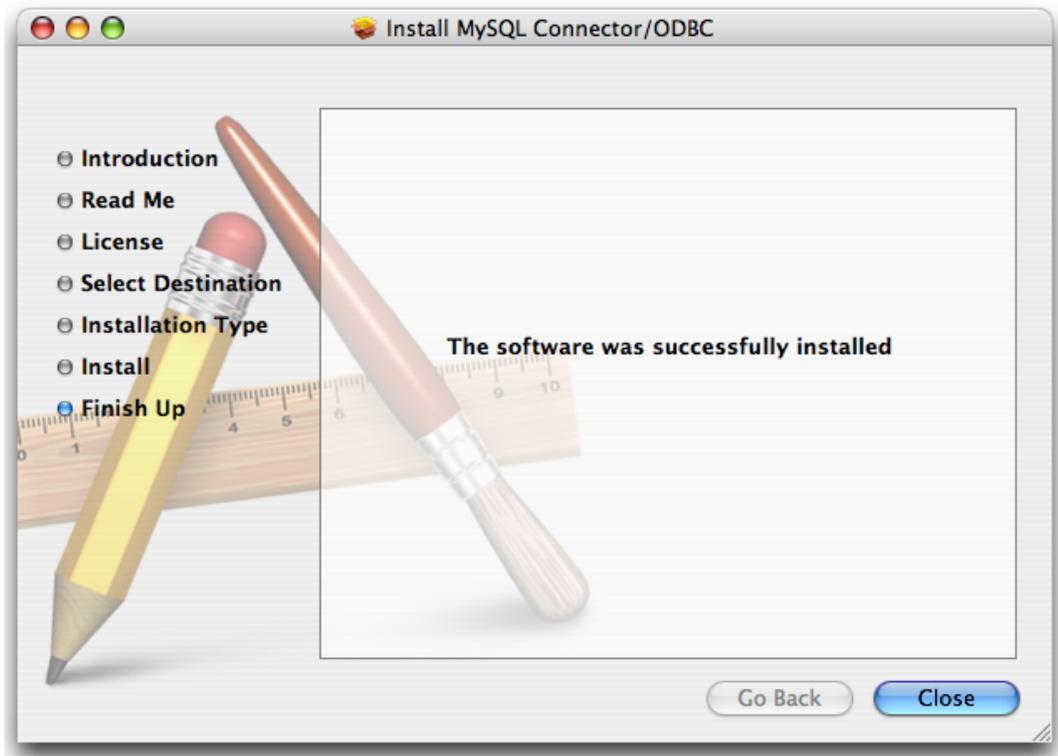

6. Choose a location to install the MyODBC drivers and the ODBC Administrator application. You must install the files onto a drive with an operating system and you may be limited in the choices available. Select the drive you want to use, and then click [Continue](#).

7. The installer will automatically select the files that need to be installed on your machine. Click [Install](#) to continue. The installer will copy the necessary files to your machine. A progress bar will be shown indicating the installation progress.

8. When installation has been completed you will get a window like the one shown below. Click **Close** to close and quit the installer.

25.1.2.4. Installing MyODBC from a source distribution

Installing MyODBC from a source distribution gives you greater flexibility in the contents and installation location of the MyODBC components. It also enables you to build and install MyODBC on platforms where a pre-compiled binary is not available.

MyODBC sources are available either as a downloadable package, or through the revision control system used by the MyODBC developers.

25.1.2.4.1. Installing MyODBC from a Source Distribution on Windows

You should only need to install MyODBC from source on Windows if you want to change or modify the source or installation. If you are unsure whether to install from source, please use the binary installation detailed in [Section 25.1.2.3.1, “Installing MyODBC from a Binary Distribution on Windows”](#).

Installing MyODBC from source on Windows requires a number of different tools and packages:

- MDAC, Microsoft Data Access SDK from <http://www.microsoft.com/data/>.
- Suitable C compiler, such as Microsoft Visual C++ or the C compiler included with Microsoft Visual Studio.
- Compatible `make` tool. Microsoft's `nmake` is used in the examples in this section.
- MySQL client libraries and include files from MySQL 4.0.0 or higher. (Preferably MySQL 4.0.16 or higher). This is required because MyODBC uses new calls and structures that exist only starting from this version of the library. To get the client libraries and include files, visit <http://dev.mysql.com/downloads/>.

25.1.2.4.1.1. Building MyODBC 3.51

MyODBC source distributions include `Makefiles` that require the `nmake` or other `make` utility. In the distribution, you can find `Makefile` for building the release version and `Makefile_debug` for building debugging versions of the driver libraries and DLLs.

To build the driver, use this procedure:

1. Download and extract the sources to a folder, then change directory into that folder. The following command assumes the folder is named `myodbc3-src`:

```
C:\> cd myodbc3-src
```

2. Edit `Makefile` to specify the correct path for the MySQL client libraries and header files. Then use the following commands to build and install the release version:

```
C:\> nmake -f Makefile
C:\> nmake -f Makefile install
```

`nmake -f Makefile` builds the release version of the driver and places the binaries in subdirectory called `Release`.

`nmake -f Makefile install` installs (copies) the driver DLLs and libraries (`myodbc3.dll`, `myodbc3.lib`) to your system directory.

3. To build the debug version, use `Makefile_Debug` rather than `Makefile`, as shown below:

```
C:\> nmake -f Makefile_debug
C:\> nmake -f Makefile_debug install
```

4. You can clean and rebuild the driver by using:

```
C:\> nmake -f Makefile_clean
C:\> nmake -f Makefile_install
```

Note:

- Make sure to specify the correct MySQL client libraries and header files path in the Makefiles (set the `MYSQL_LIB_PATH` and `MYSQL_INCLUDE_PATH` variables). The default header file path is assumed to be `C:\mysql\include`. The default library path is assumed to be `C:\mysql\lib\opt` for release DLLs and `C:\mysql\lib\debug` for debug versions.
- For the complete usage of `nmake`, visit http://msdn.microsoft.com/library/default.asp?url=/library/en-us/dv_vcce4/html/evgrfRunningNMAKE.asp.
- If you are using the Subversion tree for compiling, all Windows-specific `Makefiles` are named as `Win_Makefile*`.

25.1.2.4.1.2. Testing

After the driver libraries are copied/installed to the system directory, you can test whether the libraries are properly built by using the samples provided in the `samples` subdirectory:

```
C:\> cd samples
C:\> nmake -f Makefile_all
```

25.1.2.4.1.3. Building MyODBC 2.50

The MyODBC 2.50 source distribution includes VC workspace files. You can build the driver using these files (`.dsp` and `.dsw`) directly by loading them from Microsoft Visual Studio 6.0 or higher.

25.1.2.4.2. Installing MyODBC from a Source Distribution on Unix

You need the following tools to build MySQL from source on Unix:

- A working ANSI C++ compiler. `gcc` 2.95.2 or later, `egcs` 1.0.2 or later or `egcs 2.91.66`, SGI C++, and SunPro C++ are some of the compilers that are known to work.
- A good `make` program. GNU `make` is always recommended and is sometimes required.
- MySQL client libraries and include files from MySQL 4.0.0 or higher. (Preferably MySQL 4.0.16 or higher). This is required because MyODBC uses new calls and structures that exist only starting from this version of the library. To get the client libraries and include files, visit <http://dev.mysql.com/downloads/>.

If you have built your own MySQL server and/or client libraries from source then you must have used the `--enable-thread-safe-client` option to `configure` when the libraries were built.

You should also ensure that the `libmysqlclient` library were built and installed as a shared lib-

rary.

- A compatible ODBC manager must be installed. MyODBC is known to work with the `iODBC` and `unixODBC` managers. See [Section 25.1.1.2.2, “ODBC Driver Managers”](#), for more information.
- If you are using a character set that isn't compiled into the MySQL client library then you need to install the MySQL character definitions from the `charsets` directory into `SHAREDIR` (by default, `/usr/local/mysql/share/mysql/charsets`). These should be in place if you have installed the MySQL server on the same machine. See [Chapter 10, *Character Set Support*](#), for more information on character set support.

Once you have all the required files, unpack the source files to a separate directory, you then have to run `configure` and build the library using `make`.

25.1.2.4.2.1. Typical `configure` Options

The `configure` script gives you a great deal of control over how you configure your MyODBC build. Typically you do this using options on the `configure` command line. You can also affect `configure` using certain environment variables. For a list of options and environment variables supported by `configure`, run this command:

```
shell> ./configure --help
```

Some of the more commonly used `configure` options are described here:

1. To compile MyODBC, you need to supply the MySQL client include and library files path using the `--with-mysql-path=DIR` option, where `DIR` is the directory where MySQL is installed.

MySQL compile options can be determined by running `DIR/bin/mysql_config`.

2. Supply the standard header and library files path for your ODBC Driver Manager (`iODBC` or `unixODBC`).
 - If you are using `iODBC` and `iODBC` is not installed in its default location (`/usr/local`), you might have to use the `--with-iodbc=DIR` option, where `DIR` is the directory where `iODBC` is installed.

If the `iODBC` headers do not reside in `DIR/include`, you can use the `--with-iodbc-includes=INCDIR` option to specify their location.

The applies to libraries. If they are not in `DIR/lib`, you can use the `--with-iodbc-libs=LIBDIR` option.

- If you are using `unixODBC`, use the `--with-unixODBC=DIR` option (case sensitive) to make `configure` look for `unixODBC` instead of `iODBC` by default, `DIR` is the directory where `unixODBC` is installed.

If the `unixODBC` headers and libraries aren't located in `DIR/include` and `DIR/lib`, use the `--with-unixODBC-includes=INCDIR` and `--with-unixODBC-libs=LIBDIR` options.

3. You might want to specify an installation prefix other than `/usr/local`. For example, to install the MyODBC drivers in `/usr/local/odbc/lib`, use the `--prefix=/usr/local/odbc` option.

The final configuration command looks something like this:

```
shell> ./configure --prefix=/usr/local \
--with-iodbc=/usr/local \
--with-mysql-path=/usr/local/mysql
```

25.1.2.4.2.2. Additional configure Options

There are a number of other options that you need, or want, to set when configuring the MyODBC driver before it is built.

- To link the driver with MySQL thread safe client libraries `libmysqlclient_r.so` or `libmysqlclient_r.a`, you must specify the following `configure` option:

```
--enable-thread-safe
```

and can be disabled (default) using

```
--disable-thread-safe
```

This option enables the building of the driver thread-safe library `libmyodbc3_r.so` from by linking with MySQL thread-safe client library `libmysqlclient_r.so` (The extensions are OS dependent).

If the compilation with the thread-safe option fails, it may be because the correct thread-libraries on the system could not be located. You should set the value of `LIBS` to point to the correct thread library for your system.

```
LIBS="-lpthread" ./configure ..
```

- You can enable or disable the shared and static versions of MyODBC using these options:

```
--enable-shared[=yes/no]
--disable-shared
--enable-static[=yes/no]
--disable-static
```

- By default, all the binary distributions are built as non-debugging versions (configured with `--without-debug`).

To enable debugging information, build the driver from source distribution and use the `--with-debug` option when you run `configure`.

- This option is available only for source trees that have been obtained from the Subversion repository. This option does not apply to the packaged source distributions.

By default, the driver is built with the `--without-docs` option. If you would like the documentation to be built, then execute `configure` with:

```
--with-docs
```

25.1.2.4.2.3. Building and Compilation

To build the driver libraries, you have to just execute `make`.

```
shell> make
```

If any errors occur, correct them and continue the build process. If you aren't able to build, then send a

detailed email to [<myodbc@lists.mysql.com>](mailto:myodbc@lists.mysql.com) for further assistance.

25.1.2.4.2.4. Building Shared Libraries

On most platforms, MySQL does not build or support `.so` (shared) client libraries by default. This is based on our experience of problems when building shared libraries.

In cases like this, you have to download the MySQL distribution and configure it with these options:

```
--without-server --enable-shared
```

To build shared driver libraries, you must specify the `--enable-shared` option for `configure`. By default, `configure` does not enable this option.

If you have configured with the `--disable-shared` option, you can build the `.so` file from the static libraries using the following commands:

```
shell> cd MyODBC-3.51.01
shell> make
shell> cd driver
shell> CC=/usr/bin/gcc \
  $CC -bundle -flat_namespace -undefined error \
  -o .libs/libmyodbc3-3.51.01.so \
  catalog.o connect.o cursor.o dll.o error.o execute.o \
  handle.o info.o misc.o myodbc3.o options.o prepare.o \
  results.o transact.o utility.o \
  -L/usr/local/mysql/lib/mysql/ \
  -L/usr/local/iodbc/lib/ \
  -lz -lc -lmysqlclient -liodbcinst
```

Make sure to change `-liodbcinst` to `-lodbcinst` if you are using `unixODBC` instead of `iodbc`, and configure the library paths accordingly.

This builds and places the `libmyodbc3-3.51.01.so` file in the `.libs` directory. Copy this file to the MyODBC library installation directory (`/usr/local/lib` (or the `lib` directory under the installation directory that you supplied with the `--prefix`).

```
shell> cd .libs
shell> cp libmyodbc3-3.51.01.so /usr/local/lib
shell> cd /usr/local/lib
shell> ln -s libmyodbc3-3.51.01.so libmyodbc3.so
```

To build the thread-safe driver library:

```
shell> CC=/usr/bin/gcc \
  $CC -bundle -flat_namespace -undefined error \
  -o .libs/libmyodbc3_r-3.51.01.so \
  catalog.o connect.o cursor.o dll.o error.o execute.o \
  handle.o info.o misc.o myodbc3.o options.o prepare.o \
  results.o transact.o utility.o \
  -L/usr/local/mysql/lib/mysql/ \
  -L/usr/local/iodbc/lib/ \
  -lz -lc -lmysqlclient_r -liodbcinst
```

25.1.2.4.2.5. Installing Driver Libraries

To install the driver libraries, execute the following command:

```
shell> make install
```

That command installs one of the following sets of libraries:

For MyODBC 3.51:

- `libmyodbc3.so`
- `libmyodbc3-3.51.01.so`, where 3.51.01 is the version of the driver
- `libmyodbc3.a`

For thread-safe MyODBC 3.51:

- `libmyodbc3_r.so`
- `libmyodbc3-3_r.51.01.so`
- `libmyodbc3_r.a`

For MyODBC 2.5.0:

- `libmyodbc.so`
- `libmyodbc-2.50.39.so`, where 2.50.39 is the version of the driver
- `libmyodbc.a`

For more information on build process, refer to the [INSTALL](#) file that comes with the source distribution. Note that if you are trying to use the `make` from Sun, you may end up with errors. On the other hand, GNU `gmake` should work fine on all platforms.

25.1.2.4.2.6. Testing MyODBC on Unix

To run the basic samples provided in the distribution with the libraries that you built, use the following command:

```
shell> make test
```

Before running the tests, create the DSN 'myodbc3' in `odbc.ini` and set the environment variable `ODBCINI` to the correct `odbc.ini` file; and MySQL server is running. You can find a sample `odbc.ini` with the driver distribution.

You can even modify the `samples/run-samples` script to pass the desired DSN, UID, and PASSWORD values as the command-line arguments to each sample.

25.1.2.4.2.7. Building MyODBC from Source on Mac OS X

To build the driver on Mac OS X (Darwin), make use of the following `configure` example:

```
shell> ./configure --prefix=/usr/local
--with-unixODBC=/usr/local
--with-mysql-path=/usr/local/mysql
--disable-shared
--enable-gui=no
--host=powerpc-apple
```

The command assumes that the `unixODBC` and MySQL are installed in the default locations. If not, configure accordingly.

On Mac OS X, `--enable-shared` builds `.dylib` files by default. You can build `.so` files like this:

```
shell> make
shell> cd driver
shell> CC=/usr/bin/gcc \
    $CC -bundle -flat_namespace -undefined error
    -o .libs/libmyodbc3-3.51.01.so *.o
    -L/usr/local/mysql/lib/
    -L/usr/local/iodbc/lib
    -liodbcinst -lmysqlclient -lz -lc
```

To build the thread-safe driver library:

```
shell> CC=/usr/bin/gcc \
    $CC -bundle -flat_namespace -undefined error
    -o .libs/libmyodbc3-3.51.01.so *.o
    -L/usr/local/mysql/lib/
    -L/usr/local/iodbc/lib
    -liodbcinst -lmysqlclient_r -lz -lc -lpthread
```

Make sure to change the `-liodbcinst` to `-lodbcinst` in case of using `unixODBC` instead of `iODBC` and configure the libraries path accordingly.

In Apple's version of GCC, both `cc` and `gcc` are actually symbolic links to `gcc3`.

Copy this library to the `$prefix/lib` directory and symlink to `libmyodbc3.so`.

You can cross-check the output shared-library properties using this command:

```
shell> otool -LD .libs/libmyodbc3-3.51.01.so
```

25.1.2.4.2.8. Building MyODBC from Source on HP-UX

To build the driver on HP-UX 10.x or 11.x, make use of the following `configure` example:

If using `cc`:

```
shell> CC="cc" \
    CFLAGS="+z" \
    LDFLAGS="-Wl,+b:-Wl,+s" \
    ./configure --prefix=/usr/local
    --with-unixodbc=/usr/local
    --with-mysql-path=/usr/local/mysql/lib/mysql
    --enable-shared
    --enable-thread-safe
```

If using `gcc`:

```
shell> CC="gcc" \
    LDFLAGS="-Wl,+b:-Wl,+s" \
    ./configure --prefix=/usr/local
    --with-unixodbc=/usr/local
    --with-mysql-path=/usr/local/mysql
    --enable-shared
    --enable-thread-safe
```

Once the driver is built, cross-check its attributes using `chatr .libs/libmyodbc3.sl` to determine whether you need to have set the MySQL client library path using the `SHLIB_PATH` environment variable. For static versions, ignore all shared-library options and run `configure` with the `--disable-shared` option.

25.1.2.4.2.9. Building MyODBC from Source on AIX

To build the driver on AIX, make use of the following `configure` example:

```
shell> ./configure --prefix=/usr/local
```

```
--with-unixodbc=/usr/local
--with-mysql-path=/usr/local/mysql
--disable-shared
--enable-thread-safe
```

NOTE: For more information about how to build and set up the static and shared libraries across the different platforms refer to ' [Using static and shared libraries across platforms](http://www.fortran-2000.com/ArnaudRecipes/sharedlib.html) [<http://www.fortran-2000.com/ArnaudRecipes/sharedlib.html>]'.

25.1.2.4.3. Installing MyODBC from the Development Source Tree

Caution: You should read this section only if you are interested in helping us test our new code. If you just want to get MySQL Connector/ODBC up and running on your system, you should use a standard release distribution.

To be able to access the MyODBC source tree, you must have Subversion installed. Subversion is freely available from <http://subversion.tigris.org/>.

To build from the source trees, you need the following tools:

- autoconf 2.52 (or newer)
- automake 1.4 (or newer)
- libtool 1.4 (or newer)
- m4

The most recent development source tree is available from our public Subversion trees at <http://dev.mysql.com/tech-resources/sources.html>.

To checkout out the Connector/ODBC sources, change to the directory where you want the copy of the MyODBC tree to be stored, then use the following command:

```
shell> svn co http://svn.mysql.com/svnpublic/connector-odbc3
```

You should now have a copy of the entire MyODBC source tree in the directory `connector-odbc3`. To build from this source tree on Unix or Linux follow these steps:

```
shell> cd connector-odbc3
shell> aclocal
shell> autoheader
shell> autoconf
shell> automake;
shell> ./configure # Add your favorite options here
shell> make
```

For more information on how to build, refer to the `INSTALL` file located in the same directory. For more information on options to `configure`, see [Section 25.1.2.4.2.1, “Typical configure Options”](#)

When the build is done, run `make install` to install the MyODBC 3.51 driver on your system.

If you have gotten to the `make` stage and the distribution does not compile, please report it to [<myodbc@lists.mysql.com>](mailto:myodbc@lists.mysql.com).

On Windows, make use of Windows Makefiles `WIN-Makefile` and `WIN-Makefile_debug` in building the driver. For more information, see [Section 25.1.2.4.1, “Installing MyODBC from a Source Distribution on Windows”](#).

After the initial checkout operation to get the source tree, you should run `svn update` periodically update your source according to the latest version.

25.1.3. MyODBC Configuration

Before you connect to a MySQL database using the MyODBC driver you must configure an ODBC *Data Source Name*. The DSN associates the various configuration parameters required to communicate with a database to a specific name. You use the DSN in an application to communicate with the database, rather than specifying individual parameters within the application itself. DSN information can be user specific, system specific, or provided in a special file. ODBC data source names are configured in different ways, depending on your platform and ODBC driver.

25.1.3.1. Data Source Names

A Data Source Name associates the configuration parameters for communicating with a specific database. Generally a DSN consists of the following parameters:

- Name
- Hostname
- Database Name
- Login
- Password

In addition, different ODBC drivers, including MyODBC, may accept additional driver-specific options and parameters.

There are three types of DSN:

- A *System DSN* is a global DSN definition that is available to any user and application on a particular system. A System DSN can normally only be configured by a systems administrator, or by a user who has specific permissions that let them create System DSNs.
- A *User DSN* is specific to an individual user, and can be used to store database connectivity information that the user regularly uses.
- A *File DSN* uses a simple file to define the DSN configuration. File DSNs can be shared between users and machines and are therefore more practical when installing or deploying DSN information as part of an application across many machines.

DSN information is stored in different locations depending on your platform and environment.

25.1.3.2. Configuring a MyODBC DSN on Windows

The [ODBC Data Source Administrator](#) within Windows enables you to create DSNs, check driver installation and configure ODBC systems such as tracing (used for debugging) and connection pooling.

Different editions and versions of Windows store the [ODBC Data Source Administrator](#) in different locations depending on the version of Windows that you are using.

To open the [ODBC Data Source Administrator](#) in Windows Server 2003:

1. On the [Start](#) menu, choose [Administrative Tools](#), and then click [Data Sources \(ODBC\)](#).

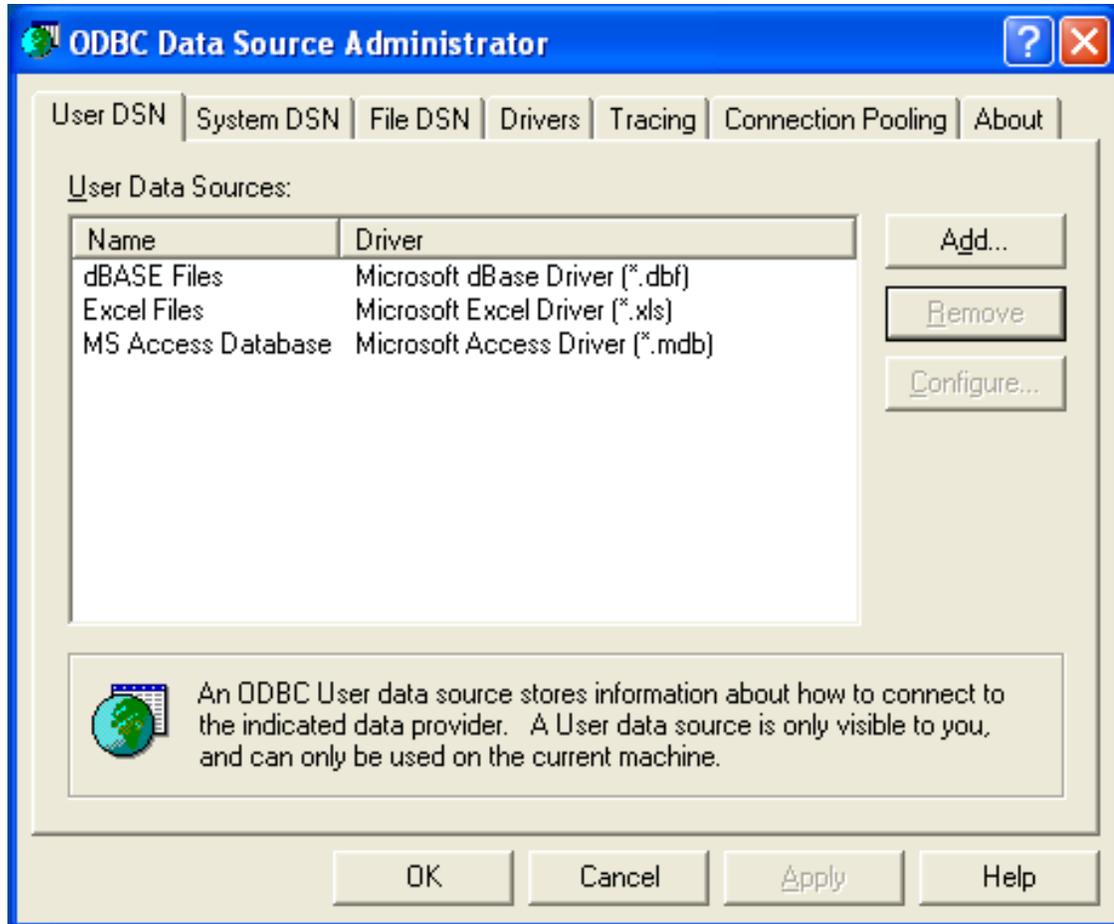

To open the [ODBC Data Source Administrator](#) in Windows 2000 Server or Windows 2000 Professional:

1. On the [Start](#) menu, choose [Settings](#), and then click [Control Panel](#).
2. In [Control Panel](#), click [Administrative Tools](#).
3. In [Administrative Tools](#), click [Data Sources \(ODBC\)](#).

To open the [ODBC Data Source Administrator](#) on Windows XP:

1. On the [Start](#) menu, click [Control Panel](#).
2. In the [Control Panel](#) when in [Category View](#) click [Performance and Maintenance](#) and then click [Administrative Tools](#). If you are viewing the [Control Panel](#) in [Classic View](#), click [Administrative Tools](#).
3. In [Administrative Tools](#), click [Data Sources \(ODBC\)](#).

Irrespective of your Windows version, you should be presented the [ODBC Data Source Administrator](#) window:

Within Windows XP, you can add the [Administrative Tools](#) folder to your [Start](#) menu to make it easier to locate the ODBC Data Source Administrator. To do this:

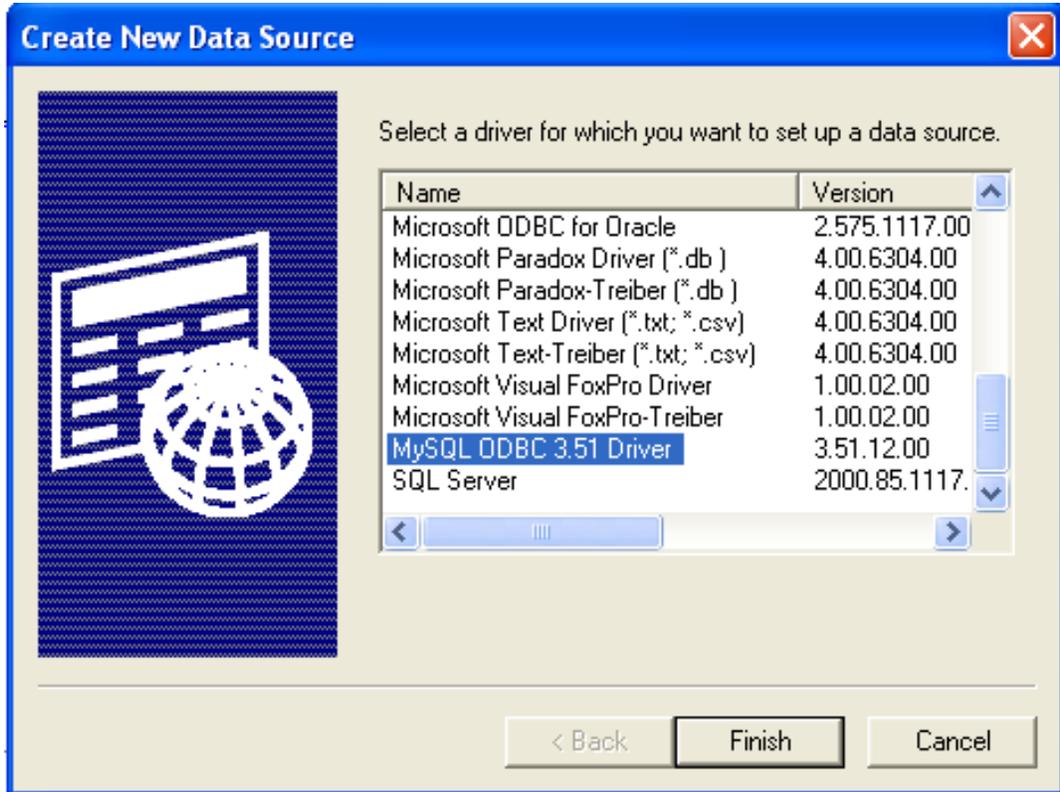

1. Right click on the [Start](#) menu.
2. Select [Properties](#).
3. Click [Customize...](#)
4. Select the [Advanced](#) tab.
5. Within [Start menu items](#), within the [System Administrative Tools](#) section, select [Display on the All Programs menu](#).

Within both Windows Server 2003 and Windows XP you may want to permanently add the [ODBC Data Source Administrator](#) to your [Start](#) menu. To do this, locate the [Data Sources \(ODBC\)](#) icon using the methods shown, then right-click on the icon and then choose [Pin to Start Menu](#).

25.1.3.2.1. Adding a MyODBC DSN on Windows

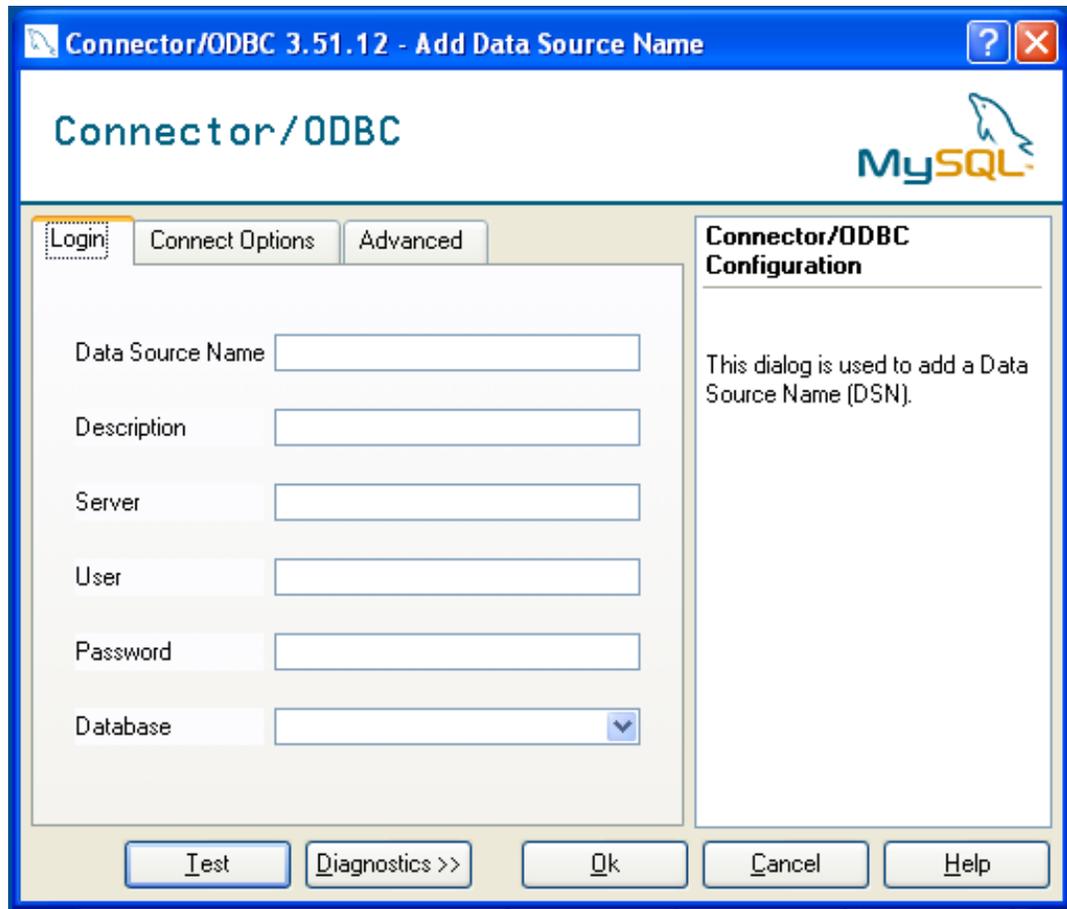

To add and configure a new MyODBC data source on Windows, use the [ODBC Data Source Administrator](#):

1. Open the [ODBC Data Source Administrator](#).
2. To create a System DSN (which will be available to all users) , select the [System DSN](#) tab. To create a User DSN, which will be unique only to the current user, click the [Add. .](#) button.
3. You will need to select the ODBC driver for this DSN.

Select [MySQL ODBC 3.51 Driver](#), then click [Finish](#).

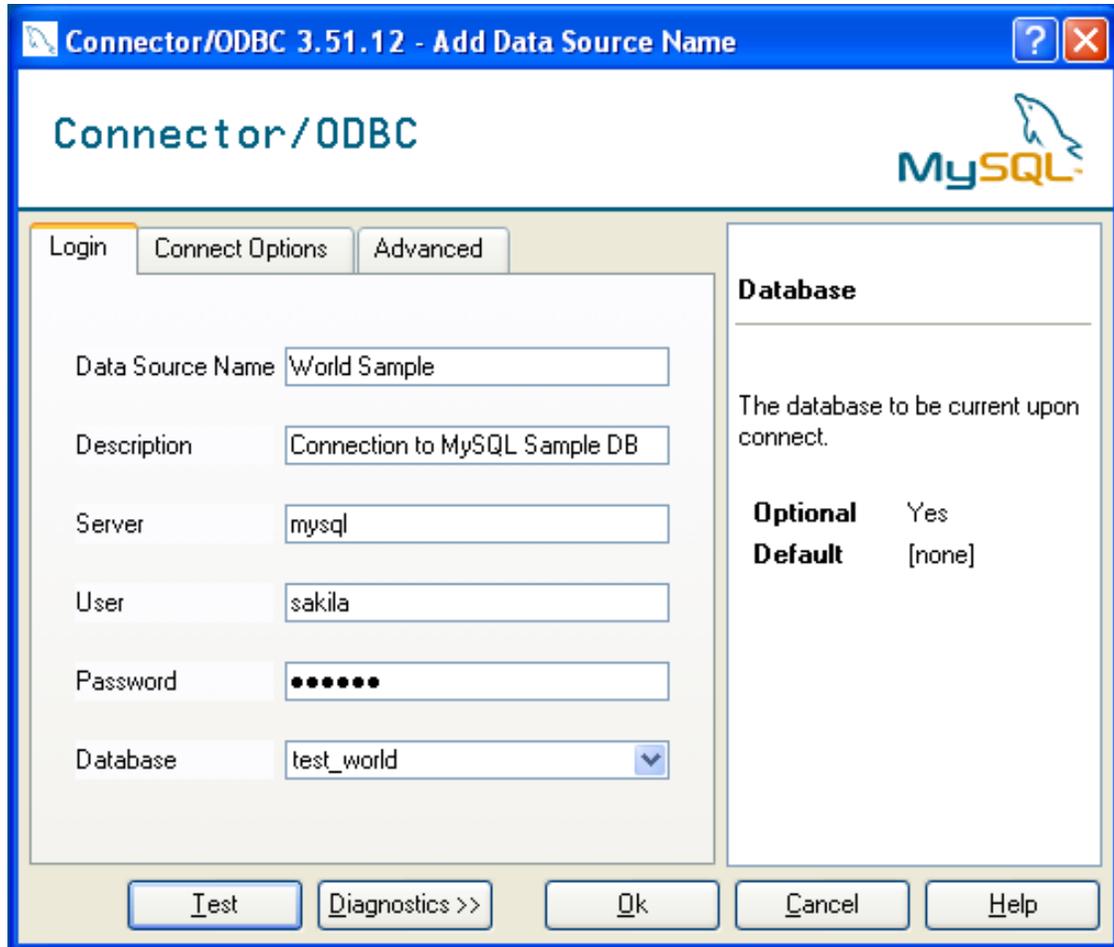

4. You now need to configure the specific fields for the DSN you are creating through the [Add Data Source Name](#) dialog.

In the **Data Source Name** box, enter the name of the data source you want to access. It can be any valid name that you choose.

5. In the **Description** box, enter some text to help identify the connection.
6. In the **Server** field, enter the name of the MySQL server host that you want to access. By default, it is `localhost`.
7. In the **User** field, enter the user name to use for this connection.
8. In the **Password** field, enter the corresponding password for this connection.
9. The **Database** popup should automatically populate with the list of databases that the user has permissions to access.
10. Click **OK** to save the DSN.

A completed DSN configuration may look like this:

25.1.3.2.2. Checking MyODBC DSN Configuration on Windows

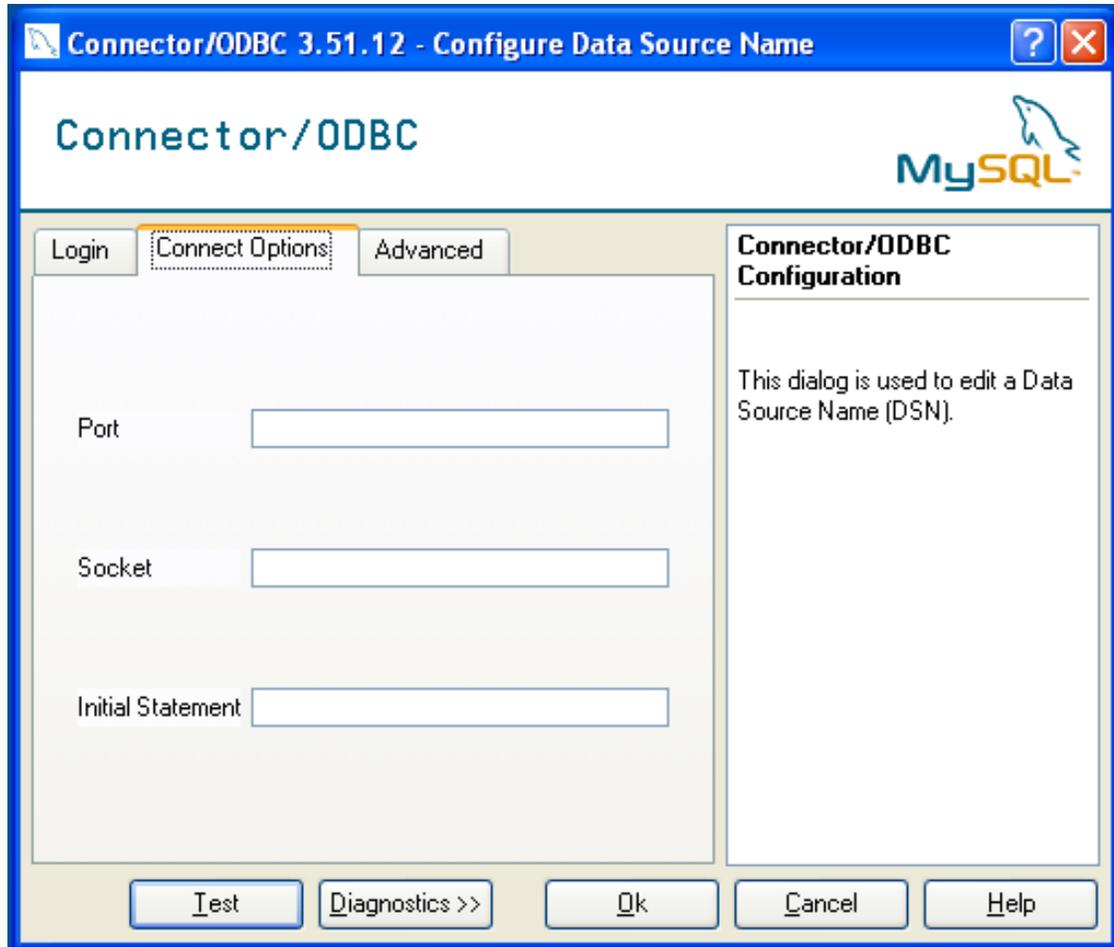

You can verify the connection using the parameters you have entered by clicking the [Test](#) button. If the connection could be made successfully, you will be notified with a [Success; connection was made!](#) dialog.

If the connection failed, you can obtain more information on the test and why it may have failed by clicking the [Diagnostics...](#) button to show additional error messages.

25.1.3.2.3. MyODBC DSN Configuration Options

You can configure a number of options for a specific DSN by using either the [Connect Options](#) or [Advanced](#) tabs in the DSN configuration dialog.

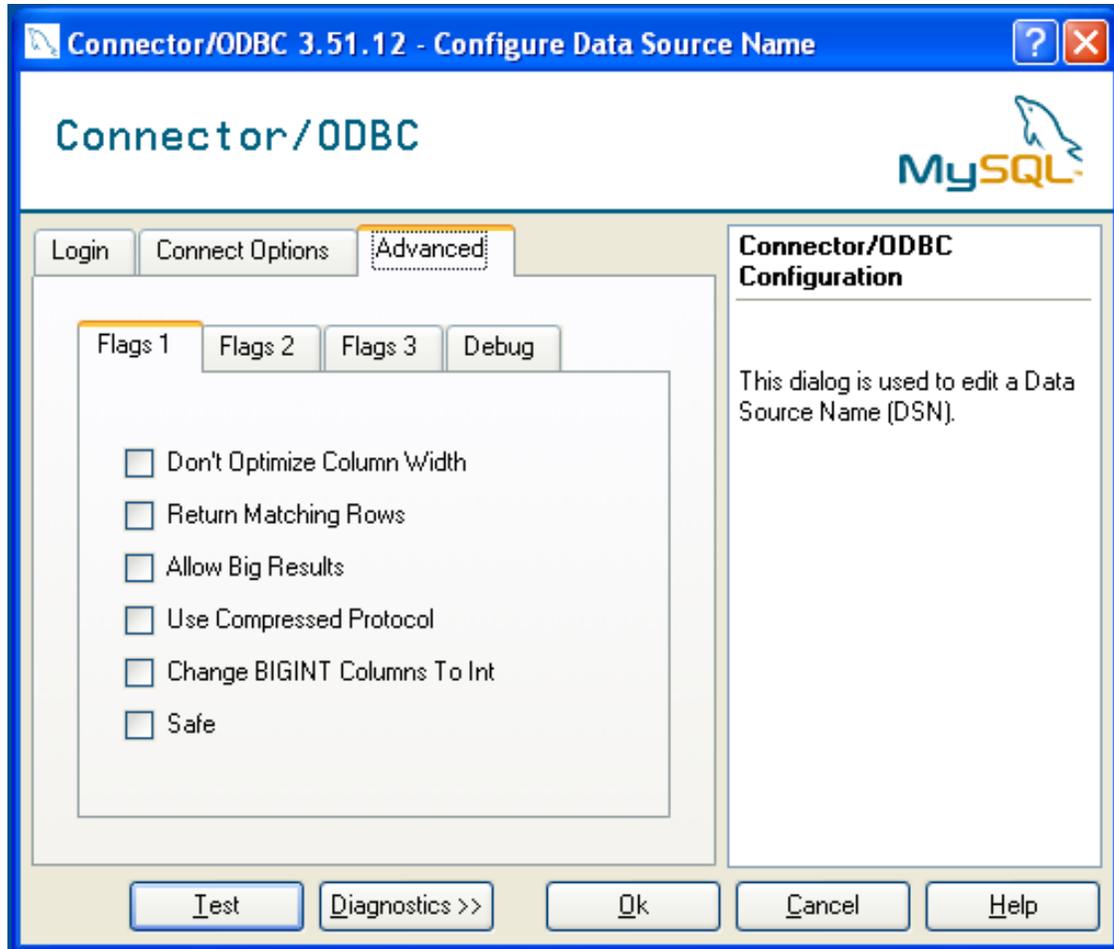

The [Connection Options](#) dialog can be seen below.

The three options you can configure are:

- **Port** sets the TCP/IP port number to use when communicating with MySQL. Communication with MySQL uses port 3306 by default. If your server is configured to use a different TCP/IP port, you must specify that port number here.
- **Socket** sets the name or location of a specific socket or Windows pipe to use when communicating with MySQL.
- **Initial Statement** defines an SQL statement that will be executed when the connection to MySQL is opened. You can use this to set MySQL options for your connection, such as setting the default character set or database to use during your connection.

The **Advanced** tab enables you to configure MyODBC connection parameters. Refer to [Section 25.1.3.5, “MyODBC Connection Parameters”](#), for information about the meaning of these options.

25.1.3.2.4. Errors and Debugging

This section answers MyODBC connection-related questions.

- **While configuring a MyODBC DSN, a `Could Not Load Translator or Setup Library` error occurs**

For more information, refer to [MS KnowledgeBase Article\(Q260558\)](http://support.microsoft.com/default.aspx?scid=kb;EN-US;q260558)

[<http://support.microsoft.com/default.aspx?scid=kb;EN-US;q260558>]. Also, make sure you have the latest valid `ct13d32.dll` in your system directory.

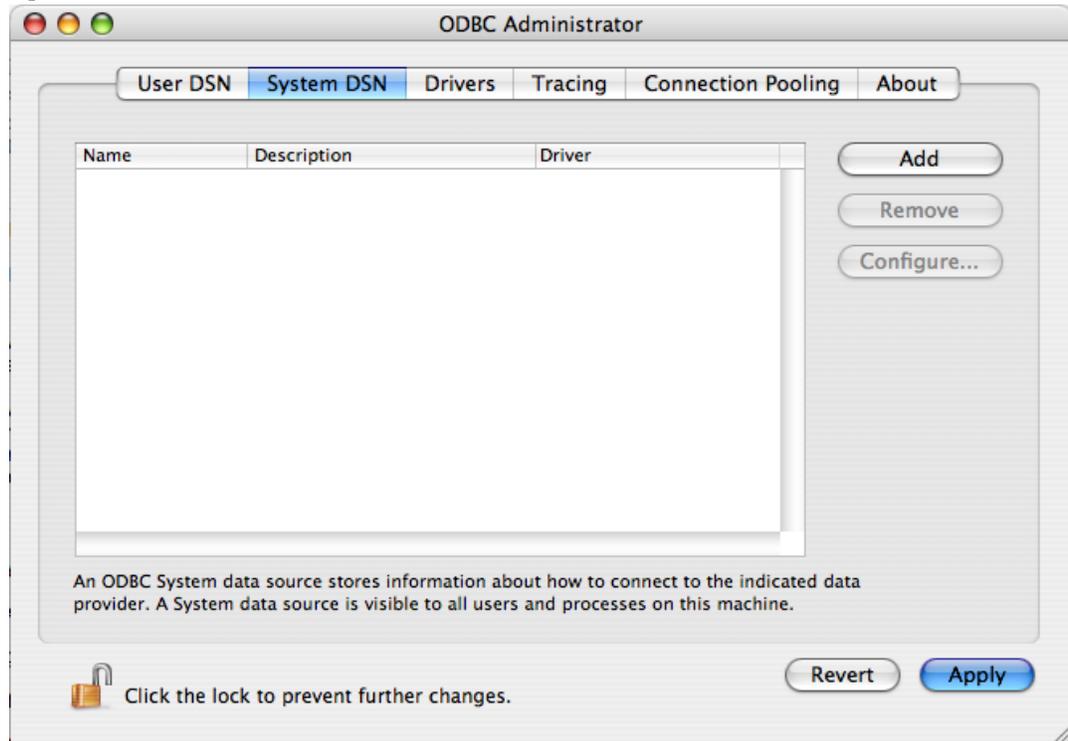

- On Windows, the default `myodbc3.dll` is compiled for optimal performance. If you want to debug MyODBC 3.51 (for example, to enable tracing), you should instead use `myodbc3d.dll`. To install this file, copy `myodbc3d.dll` over the installed `myodbc3.dll` file. Make sure to revert back to the release version of the driver DLL once you are done with the debugging because the debug version may cause performance issues. Note that the `myodbc3d.dll` isn't included in MyODBC 3.51.07 through 3.51.11. If you are using one of these versions, you should copy that DLL from a previous version (for example, 3.51.06).

For MyODBC 2.50, `myodbc.dll` and `myodbcd.dll` are used instead.

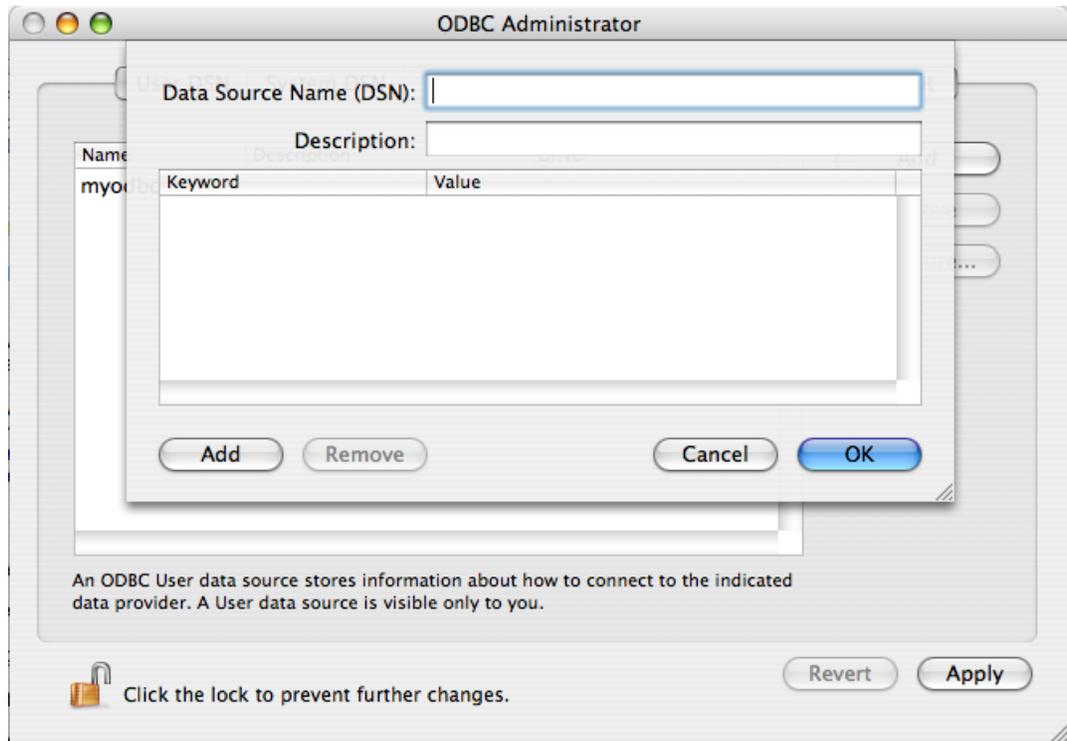

25.1.3.3. Configuring a MyODBC DSN on Mac OS X

To configure a DSN on Mac OS X you should use the ODBC Administrator. If you have Mac OS X 10.2 or earlier, refer to [Section 25.1.3.4, “Configuring a MyODBC DSN on Unix”](#). Select whether you want to create a User DSN or a System DSN. If you want to add a System DSN, you may need to authenticate with the system. You must click the padlock and enter a user and password with administrator privileges.

1. Open the ODBC Administrator from the [Utilities](#) folder in the [Applications](#) folder.

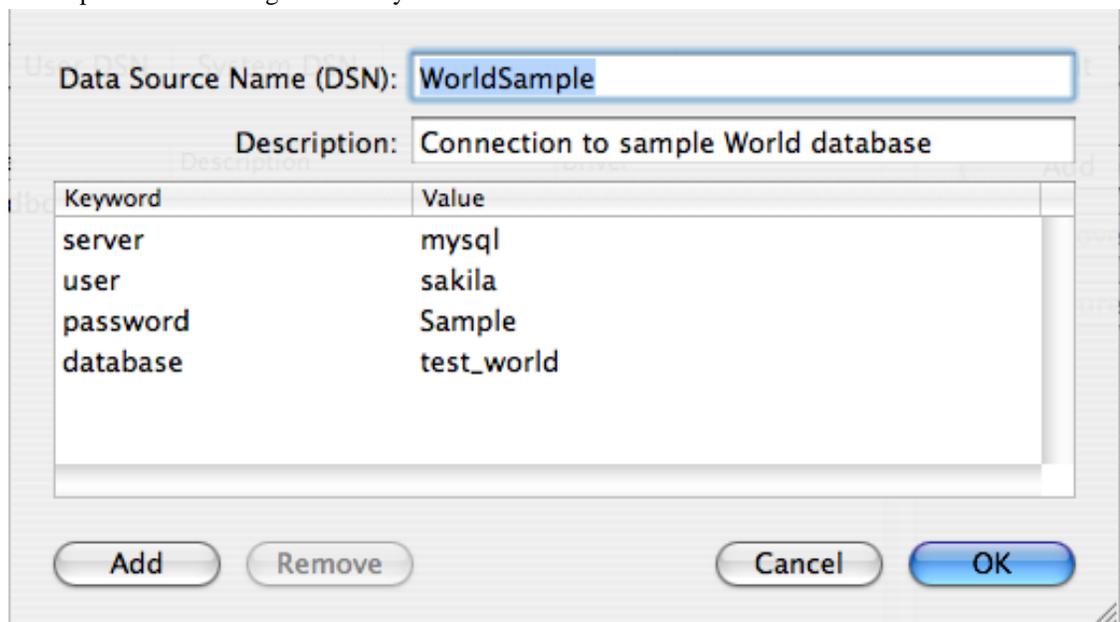

2. On the User DSN or System DSN panel, click [Add](#).
3. Select the MyODBC driver and click [OK](#).
4. You will be presented with the [Data Source Name](#) dialog. Enter The [Data Source Name](#) and an optional [Description](#) for the DSN.

5. Click **Add** to add a new keyword/value pair to the panel. You should configure at least four pairs to specify the `server`, `username`, `password` and `database` connection parameters. See [Section 25.1.3.5, “MyODBC Connection Parameters”](#).
6. Click **OK** to add the DSN to the list of configured data source names.

A completed DSN configuration may look like this:

You can configure additional ODBC options to your DSN by adding further keyword/value pairs and

setting the corresponding values. See [Section 25.1.3.5, “MyODBC Connection Parameters”](#).

25.1.3.4. Configuring a MyODBC DSN on Unix

On [Unix](#), you configure DSN entries directly in the `odbc.ini` file. Here is a typical `odbc.ini` file that configures `myodbc` and `myodbc3` as the DSN names for MyODBC 2.50 and MyODBC 3.51, respectively:

```
;
; odbc.ini configuration for MyODBC and MyODBC 3.51 drivers
;

[ODBC Data Sources]
myodbc      = MyODBC 2.50 Driver DSN
myodbc3     = MyODBC 3.51 Driver DSN

[myodbc]
Driver      = /usr/local/lib/libmyodbc.so
Description = MyODBC 2.50 Driver DSN
SERVER      = localhost
PORT        =
USER        = root
Password    =
Database    = test
OPTION      = 3
SOCKET      =

[myodbc3]
Driver      = /usr/local/lib/libmyodbc3.so
Description = MyODBC 3.51 Driver DSN
SERVER      = localhost
PORT        =
USER        = root
Password    =
Database    = test
OPTION      = 3
SOCKET      =

[Default]
Driver      = /usr/local/lib/libmyodbc3.so
Description = MyODBC 3.51 Driver DSN
SERVER      = localhost
PORT        =
USER        = root
Password    =
Database    = test
OPTION      = 3
SOCKET      =
```

Refer to the [Section 25.1.3.5, “MyODBC Connection Parameters”](#), for the list of connection parameters that can be supplied.

Note: If you are using `unixODBC`, you can use the following tools to set up the DSN:

- ODBCConfig GUI tool([HOWTO: ODBCConfig](http://www.unixodbc.org/config.html) [<http://www.unixodbc.org/config.html>])
- `odbcinst`

In some cases when using `unixODBC`, you might get this error:

```
Data source name not found and no default driver specified
```

If this happens, make sure the `ODBCINI` and `ODBCSYSINI` environment variables are pointing to the right `odbc.ini` file. For example, if your `odbc.ini` file is located in `/usr/local/etc`, set the environment variables like this:

```
export ODBCINI=/usr/local/etc/odbc.ini
```

```
export ODBCYSINI=/usr/local/etc
```

25.1.3.5. MyODBC Connection Parameters

You can specify the parameters in the following tables for MyODBC when configuring a DSN. Users on Windows can use the Options and Advanced panels when configuring a DSN to set these parameters; see the table for information on which options relate to which fields and checkboxes. On Unix and Mac OS X, use the parameter name and value as the keyword/value pair in the DSN configuration. Alternatively, you can set these parameters within the `InConnectionString` argument in the `SQLDriverConnect()` call.

Parameter	Default Value	Comment
<code>user</code>	ODBC (on Windows)	The username used to connect to MySQL.
<code>server</code>	<code>localhost</code>	The hostname of the MySQL server.
<code>database</code>		The default database.
<code>option</code>	0	Options that specify how MyODBC should work. See below.
<code>port</code>	3306	The TCP/IP port to use if <code>server</code> is not <code>localhost</code> .
<code>stmt</code>		A statement to execute when connecting to MySQL.
<code>password</code>		The password for the <code>user</code> account on <code>server</code> .
<code>socket</code>		The Unix socket file or Windows named pipe to connect to if <code>server</code> is <code>localhost</code> .

The `option` argument is used to tell MyODBC that the client isn't 100% ODBC compliant. On Windows, you normally select options by toggling the checkboxes in the connection screen, but you can also select them in the `option` argument. The following options are listed in the order in which they appear in the MyODBC connect screen:

Value	Windows Checkbox	Description
1	Don't Optimized Column Width	The client can't handle that MyODBC returns the real width of a column.
2	Return Matching Rows	The client can't handle that MySQL returns the true value of affected rows. If this flag is set, MySQL returns "found rows" instead. You must have MySQL 3.21.14 or newer to get this to work.
4	Trace Driver Calls To myodbc.log	Make a debug log in <code>C:\myodbc.log</code> on Windows, or <code>/tmp/myodbc.log</code> on Unix variants.
8	Allow Big Results	Don't set any packet limit for results and parameters.
16	Don't Prompt Upon Connect	Don't prompt for questions even if driver would like to prompt.
32	Enable Dynamic Cursor	Enable or disable the dynamic cursor support. (Not allowed in MyODBC 2.50.)
64	Ignore # in Table Name	Ignore use of database name in <code>db_name.tbl_name.col_name</code> .
128	User Manager Cursors	Force use of ODBC manager cursors (experimental).
256	Don't Use Set Locale	Disable the use of extended fetch (experimental).
512	Pad Char To Full Length	Pad <code>CHAR</code> columns to full column length.
1024	Return Table Names for SQL-	<code>SQLDescribeCol()</code> returns fully qualified column

	DescribeCol	names.
2048	Use Compressed Protocol	Use the compressed client/server protocol.
4096	Ignore Space After Function Names	Tell server to ignore space after function name and before ' (' (needed by PowerBuilder). This makes all function names keywords.
8192	Force Use of Named Pipes	Connect with named pipes to a <code>mysqld</code> server running on NT.
16384	Change BIGINT Columns to Int	Change <code>BIGINT</code> columns to <code>INT</code> columns (some applications can't handle <code>BIGINT</code>).
32768	No Catalog (exp)	Return 'user' as <code>Table_qualifier</code> and <code>Table_owner</code> from <code>SQLTables</code> (experimental).
65536	Read Options From <code>my.cnf</code>	Read parameters from the <code>[client]</code> and <code>[odbc]</code> groups from <code>my.cnf</code> .
131072	Safe	Add some extra safety checks (should not be needed but...).
262144	Disable transaction	Disable transactions.
524288	Save queries to <code>myodbc.sql</code>	Enable query logging to <code>c:\myodbc.sql(/tmp/myodbc.sql)</code> file. (Enabled only in debug mode.)
1048576	Don't Cache Result (forward only cursors)	Do not cache the results locally in the driver, instead read from server (<code>mysql_use_result()</code>). This works only for forward-only cursors. This option is very important in dealing with large tables when you don't want the driver to cache the entire result set.
2097152	Force Use Of Forward Only Cursors	Force the use of <code>Forward-only</code> cursor type. In case of applications setting the default static/dynamic cursor type, and one wants the driver to use non-cache result sets, then this option ensures the forward-only cursor behavior.

To select multiple options, add together their values. For example, setting `option` to 12 (4+8) gives you debugging without packet limits.

The following table shows some recommended `option` values for various configurations:

Configuration	Option Value
Microsoft Access, Visual Basic	3
Driver trace generation (Debug mode)	4
Microsoft Access (with improved DELETE queries)	35
Large tables with too many rows	2049
Sybase PowerBuilder	135168
Query log generation (Debug mode)	524288
Generate driver trace as well as query log (Debug mode)	524292
Large tables with no-cache results	3145731

25.1.3.6. Connecting Without a Predefined DSN

You can connect to the MySQL server using `SQLDriverConnect`, by specifying the `DRIVER` name field. Here are the connection strings for MyODBC using DSN-Less connections:

For MyODBC 2.50:

```
ConnectionString = "DRIVER={MySQL};\  
SERVER=localhost;\  
DATABASE=test;\  
USER=venu;\  
PASSWORD=venu;\  
OPTION=3; "
```

For MyODBC 3.51:

```
ConnectionString = "DRIVER={MySQL ODBC 3.51 Driver};\  
SERVER=localhost;\  
DATABASE=test;\  
USER=venu;\  
PASSWORD=venu;\  
OPTION=3; "
```

If your programming language converts backslash followed by whitespace to a space, it is preferable to specify the connection string as a single long string, or to use a concatenation of multiple strings that does not add spaces in between. For example:

```
ConnectionString = "DRIVER={MySQL ODBC 3.51 Driver};"  
"SERVER=localhost;"  
"DATABASE=test;"  
"USER=venu;"  
"PASSWORD=venu;"  
"OPTION=3;"
```

Note. Note that on Mac OS X you may need to specify the full path to the MyODBC driver library.

Refer to the [Section 25.1.3.5, “MyODBC Connection Parameters”](#), for the list of connection parameters that can be supplied.

25.1.3.7. ODBC Connection Pooling

Connection pooling enables the ODBC driver to re-use existing connections to a given database from a pool of connections, instead of opening a new connection each time the database is accessed. By enabling connection pooling you can improve the overall performance of your application by lowering the time taken to open a connection to a database in the connection pool.

For more information about connection pooling: <http://support.microsoft.com/default.aspx?scid=kb;EN-US;q169470>.

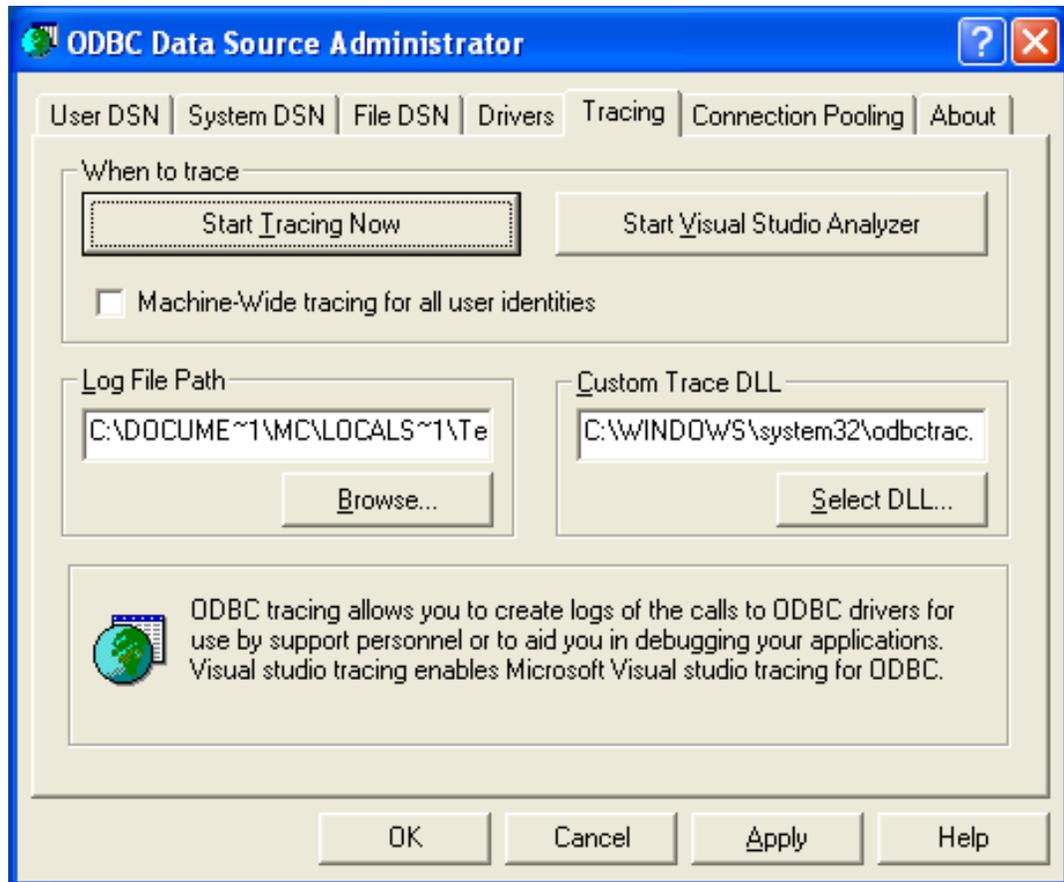

25.1.3.8. Getting an ODBC Trace File

If you encounter difficulties or problems with MyODBC, you should start by making a log file from the [ODBC Manager](#) and MyODBC. This is called *tracing*, and is enabled through the ODBC Manager. The procedure for this differs for Windows, Mac OS X and Unix.

25.1.3.8.1. Enabling ODBC Tracing on Windows

To enable the trace option on Windows:

1. The [Tracing](#) tab of the ODBC Data Source Administrator dialog box enables you to configure the way ODBC function calls are traced.

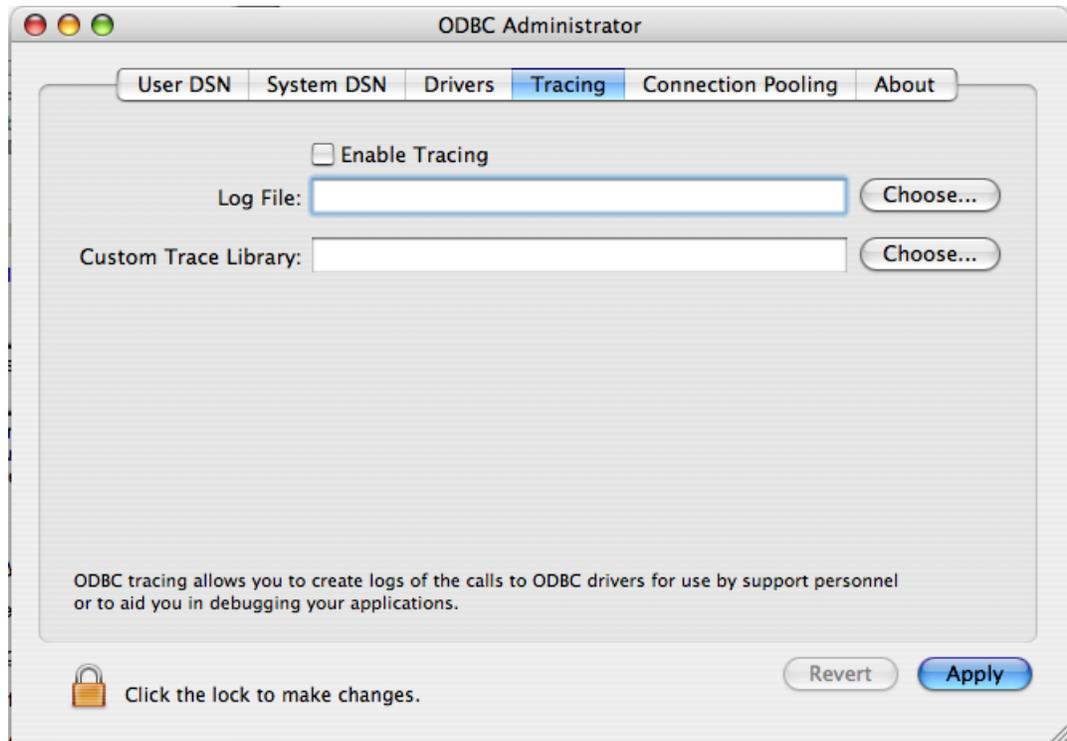

2. When you activate tracing from the [Tracing](#) tab, the [Driver Manager](#) logs all ODBC function calls for all subsequently run applications.
3. ODBC function calls from applications running before tracing is activated are not logged. ODBC function calls are recorded in a log file you specify.
4. Tracing ceases only after you click [Stop Tracing Now](#). Remember that while tracing is on, the log file continues to increase in size and that tracing affects the performance of all your ODBC applications.

25.1.3.8.2. Enabling ODBC Tracing on Mac OS X

To enable the trace option on Mac OS X 10.3 or later you should use the [Tracing](#) tab within ODBC Administrator .

1. Open the ODBC Administrator.
2. Select the [Tracing](#) tab.

3. Select the `Enable Tracing` checkbox.
4. Enter the location where you want to save the Tracing log. If you want to append information to an existing log file, click the `Choose...` button.

25.1.3.8.3. Enabling ODBC Tracing on Unix

To enable the trace option on Mac OS X 10.2 (or earlier) or Unix you must add the `trace` option to the ODBC configuration:

1. On Unix, you need to explicitly set the `Trace` option in the `ODBC.INI` file.

Set the tracing `ON` or `OFF` by using `TraceFile` and `Trace` parameters in `odbc.ini` as shown below:

```
TraceFile = /tmp/odbc.trace
Trace     = 1
```

`TraceFile` specifies the name and full path of the trace file and `Trace` is set to `ON` or `OFF`. You can also use `1` or `YES` for `ON` and `0` or `NO` for `OFF`. If you are using `ODBCConfig` from `unixODBC`, then follow the instructions for tracing `unixODBC` calls at [HOWTO-ODBCConfig](http://www.unixodbc.org/config.html) [<http://www.unixodbc.org/config.html>].

25.1.3.8.4. Enabling a MyODBC Log

To generate a MyODBC log, do the following:

1. Within Windows, enable the `Trace MyODBC` option flag in the MyODBC connect/configure

screen. The log is written to file `C:\myodbc.log`. If the trace option is not remembered when you are going back to the above screen, it means that you are not using the `myodbc.dll` driver, see [Section 25.1.3.2.4, “Errors and Debugging”](#).

On Mac OS X, Unix, or if you are using DSN-Less connection, then you need to supply `OPTION=4` in the connection string or set the corresponding keyword/value pair in the DSN.

2. Start your application and try to get it to fail. Then check the MyODBC trace file to find out what could be wrong.

If you need help determining what is wrong, see [Section 25.1.7.1, “MyODBC Community Support”](#).

25.1.4. MyODBC Examples

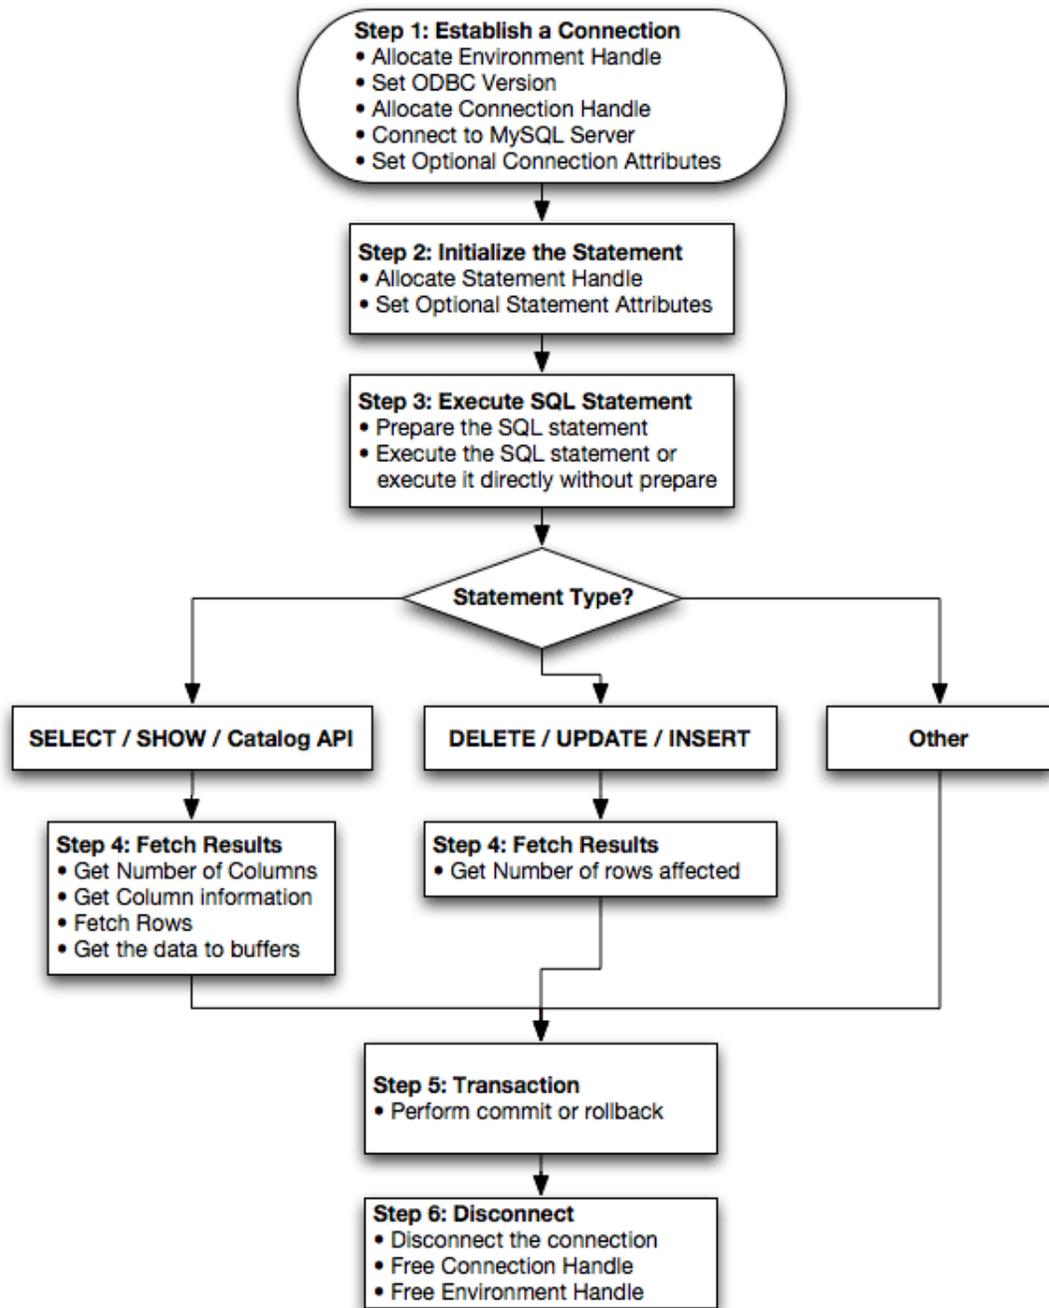

Once you have configured a DSN to provide access to a database, how you access and use that connection is dependent on the application or programming language. As ODBC is a standardized interface, any application or language that supports ODBC can use the DSN and connect to the configured database.

25.1.4.1. Basic MyODBC Application Steps

Interacting with a MySQL server from an applications using the MyODBC typically involves the following operations:

- Configure the MyODBC DSN
- Connect to MySQL server
- Initialization operations
- Execute SQL statements
- Retrieve results
- Perform Transactions
- Disconnect from the server

Most applications use some variation of these steps. The basic application steps are shown in the following diagram:

25.1.4.2. Step-by-step Guide to Connecting to a MySQL Database through MyODBC

A typical installation situation where you would install MyODBC is when you want to access a database on a Linux or Unix host from a Windows machine.

As an example of the process required to set up access between two machines, the steps below take you through the basic steps. These instructions assume that you want to connect to system ALPHA from system BETA with a username and password of `myuser` and `mypassword`.

On system ALPHA (the MySQL server) follow these steps:

1. Start the MySQL server.
2. Use `GRANT` to set up an account with a username of `myuser` that can connect from system BETA using a password of `myuser` to the database `test`:

```
GRANT ALL ON test.* to 'myuser'@'BETA' IDENTIFIED BY 'mypassword';
```

For more information about MySQL privileges, refer to [Section 5.9, “MySQL User Account Management”](#).

On system BETA (the MyODBC client), follow these steps:

1. Configure a MyODBC DSN using parameters that match the server, database and authentication information that you have just configured on system ALPHA.

Parameter	Value	Comment
DSN	remote_test	A name to identify the connection.
SERVER	ALPHA	The address of the remote server.
DATABASE	test	The name of the default database.
USER	myuser	The username configured for access to this database.
PASSWORD	mypassword	The password for <code>myuser</code> .

2. Using an ODBC-capable application, such as Microsoft Office, connect to the MySQL server using the DSN you have just created. If the connection fails, use tracing to examine the connection process. See [Section 25.1.3.8, “Getting an ODBC Trace File”](#), for more information.

25.1.4.3. MyODBC and Third-Party ODBC Tools

Once you have configured your MyODBC DSN, you can access your MySQL database through any application that supports the ODBC interface, including programming languages and third-party applications. This section contains guides and help on using MyODBC with various ODBC-compatible tools and applications, including Microsoft Word, Microsoft Excel and Adobe/Macromedia ColdFusion.

25.1.4.3.1. Applications Tested with MyODBC

MyODBC has been tested with the following applications:

Publisher	Application	Notes
Adobe	ColdFusion	Formerly Macromedia ColdFusion
Borland	C++ Builder	
	Builder 4	
	Delphi	
Business Objects	Crystal Reports	
Claris	Filemaker Pro	
Corel	Paradox	

Computer Associates	Visual Objects	Also known as CAVO
	AllFusion ERwin Data Modeler	
Gupta	Team Developer	Previously known as Centura Team Developer; Gupta SQL/Windows
Gensym	G2-ODBC Bridge	
Inline	iHTML	
Lotus	Notes	Versions 4.5 and 4.6
Microsoft	Access	
	Excel	
	Visio Enterprise	
	Visual C++	
	Visual Basic	
	ODBC.NET	Using C#, Visual Basic, C++
	FoxPro	
	Visual Interdev	
OpenOffice.org	OpenOffice.org	
Perl	DBD::ODBC	
Pervasive Software	DataJunction	
Sambar Technologies	Sambar Server	
SPSS	SPSS	
SoftVelocity	Clarion	
SQLExpress	SQLExpress for Xbase++	
Sun	StarOffice	
SunSystems	Vision	
Sybase	PowerBuilder	
	PowerDesigner	
theKompany.com	Data Architect	

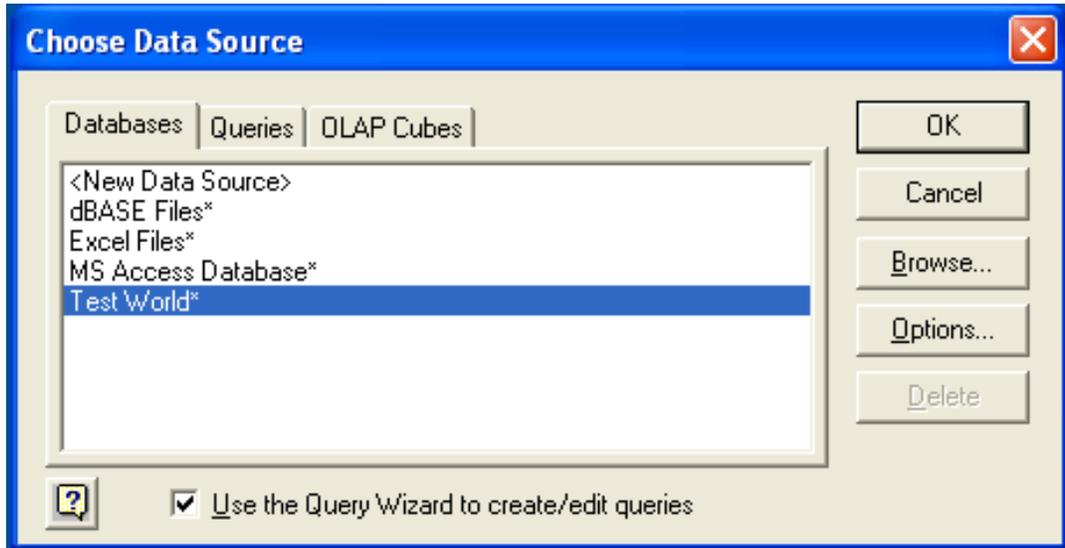

If you know of any other applications that work with MyODBC, please send mail to myodbc@lists.mysql.com about them.

25.1.4.3.2. Using MyODBC with Microsoft Word or Excel

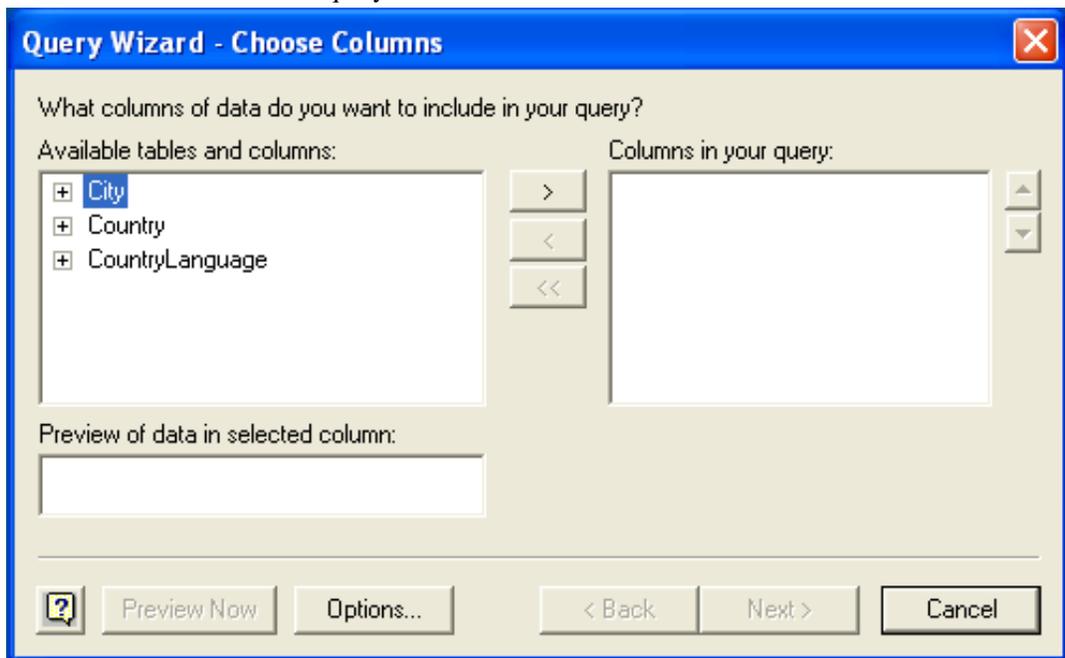

You can use Microsoft Word and Microsoft Excel to access information from a MySQL database using MyODBC. Within Microsoft Word, this facility is most useful when importing data for mailmerge, or for tables and data to be included in reports. Within Microsoft Excel, you can execute queries on your MySQL server and import the data directly into an Excel Worksheet, presenting the data as a series of rows and columns.

With both applications, data is accessed and imported into the application using Microsoft Query , which enables you to execute a query though an ODBC source. You use Microsoft Query to build the SQL statement to be executed, selecting the tables, fields, selection criteria and sort order. For example, to insert information from a table in the World test database into an Excel spreadsheet, using the DSN samples shown in [Section 25.1.3, “MyODBC Configuration”](#):

1. Create a new Worksheet.
2. From the **Data** menu, choose **Import External Data**, and then select **New Database Query**.
3. Microsoft Query will start. First, you need to choose the data source, by selecting an existing Data Source Name.

4. Within the **Query Wizard**, you must choose the columns that you want to import. The list of tables available to the user configured through the DSN is shown on the left, the columns that will be added to your query are shown on the right. The columns you choose are equivalent to those in the first section of a **SELECT** query. Click **Next** to continue.

5. You can filter rows from the query (the equivalent of a **WHERE** clause) using the **Filter Data** dialog. Click **Next** to continue.

Query Wizard - Filter Data

Filter the data to specify which rows to include in your query.
If you don't want to filter the data, click Next.

Column to filter: Only include rows where:

Name
CountryCode
District
Population

Name

 And Or

 And Or

 And Or

 < Back Next > Cancel

6. Select an (optional) sort order for the data. This is equivalent to using a `ORDER BY` clause in your SQL query. You can select up to three fields for sorting the information returned by the query. Click **Next** to continue.

Query Wizard - Sort Order

Specify how you want your data sorted.
If you don't want to sort the data, click Next.

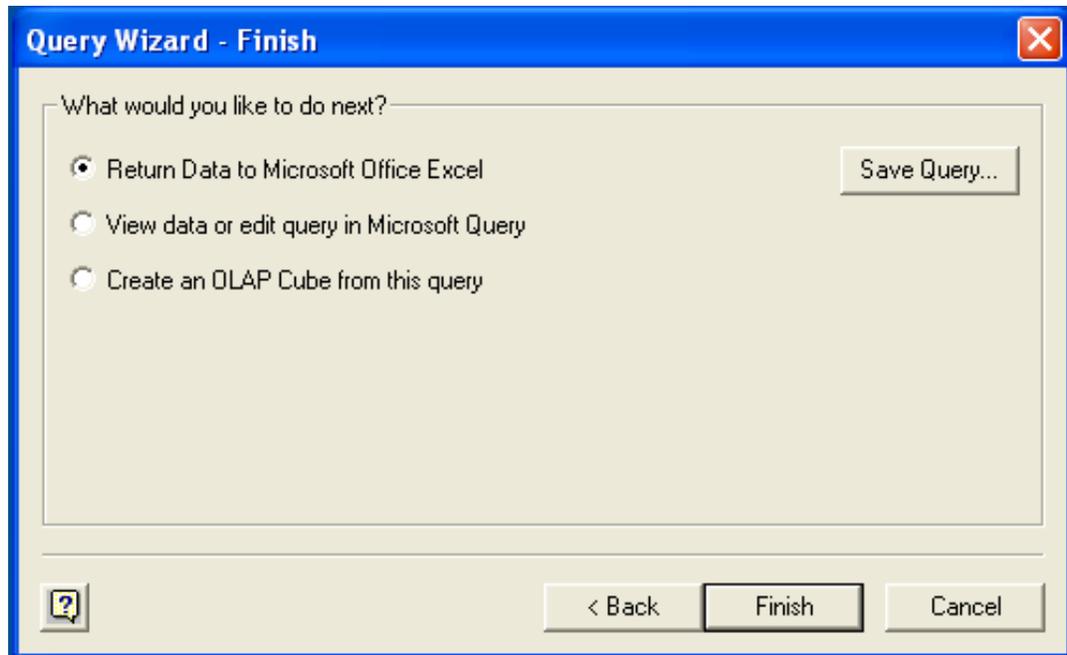

Sort by Ascending
 Descending

Then by Ascending
 Descending

Then by Ascending
 Descending

 < Back Next > Cancel

7. Select the destination for your query. You can select to return the data Microsoft Excel, where you can choose a worksheet and cell where the data will be inserted; you can continue to view the query and results within Microsoft Query, where you can edit the SQL query and further filter and sort the information returned; or you can create an OLAP Cube from the query, which can then be used directly within Microsoft Excel. Click **Finish**.

The same process can be used to import data into a Word document, where the data will be inserted as a table. This can be used for mail merge purposes (where the field data is read from a Word table), or where you want to include data and reports within a report or other document.

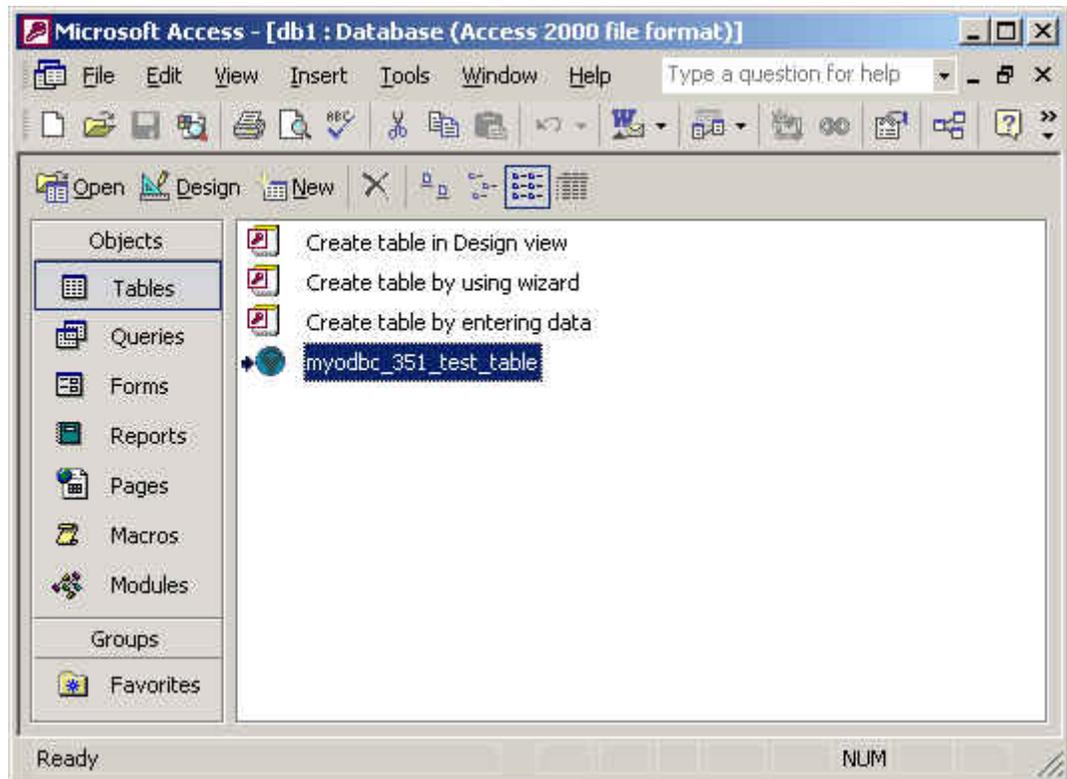

25.1.4.3.3. Using MyODBC and Microsoft Access

You can use MySQL database with Microsoft Access using MyODBC. The MySQL database can be used as an import source, an export source, or as a linked table for direct use within an Access application, so you can use Access as the front-end interface to a MySQL database.

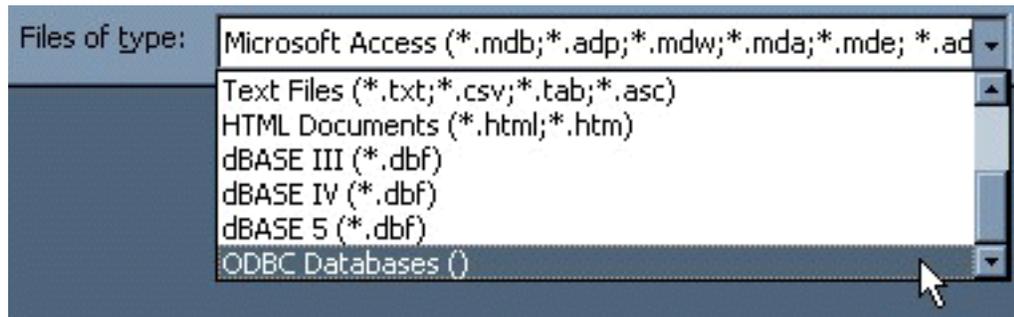

25.1.4.3.3.1. Exporting Access Data to MySQL

To export a table of data from an Access database to MySQL, follow these instructions:

1. When you open an Access database or an Access project, a Database window appears. It displays shortcuts for creating new database objects and opening existing objects.

2. Click the name of the [table](#) or [query](#) you want to export, and then in the [File](#) menu, select [Export](#).
3. In the [Export Object Type Object name To](#) dialog box, in the [Save As Type](#) box, select [ODBC Databases \(\)](#) as shown here:

4. In the [Export](#) dialog box, enter a name for the file (or use the suggested name), and then select [OK](#).
5. The [Select Data Source](#) dialog box is displayed; it lists the defined data sources for any ODBC drivers installed on your computer. Click either the [File Data Source](#) or [Machine Data Source](#) tab, and then double-click the [MyODBC](#) or [MyODBC 3.51](#) data source that you want to export to. To define a new data source for [MyODBC](#), please [Section 25.1.3.2, "Configuring a MyODBC DSN on Windows"](#).

Microsoft Access connects to the MySQL Server through this data source and exports new tables and/or data.

25.1.4.3.3.2. Importing MySQL Data to Access

To import or link a table or tables from MySQL to Access, follow these instructions:

1. Open a database, or switch to the Database window for the open database.
2. To import tables, on the **File** menu, point to **Get External Data**, and then click **Import**. To link tables, on the **File** menu, point to **Get External Data**, and then click **Link Tables**.
3. In the **Import** (or **Link**) dialog box, in the **Files Of Type** box, select **ODBC Databases ()**. The **Select Data Source** dialog box lists the defined data sources. The **Select Data Source** dialog box is displayed; it lists the defined data source names.
4. If the ODBC data source that you selected requires you to log on, enter your login ID and password (additional information might also be required), and then click **OK**.
5. Microsoft Access connects to the MySQL server through **ODBC data source** and displays the list of tables that you can **import** or **link**.
6. Click each table that you want to **import** or **link**, and then click **OK**. If you're linking a table and it doesn't have an index that uniquely identifies each record, Microsoft Access displays a list of the fields in the linked table. Click a field or a combination of fields that uniquely identifies each record, and then click **OK**.

25.1.4.3.3.3. Linking MySQL Data to Access Tables

Use the following procedure to view or to refresh links when the structure or location of a linked table has changed. The **Linked Table Manager** lists the paths to all currently linked tables.

To view or refresh links:

1. Open the database that contains links to tables.
2. On the **Tools** menu, point to **Add-ins (Database Utilities** in Access 2000 or newer), and then click **Linked Table Manager**.
3. Select the check box for the tables whose links you want to refresh.
4. Click **OK** to refresh the links.

Microsoft Access confirms a successful refresh or, if the table wasn't found, displays the **Select New Location of <table name>** dialog box in which you can specify its the table's new location. If several selected tables have moved to the new location that you specify, the **Linked Table Manager** searches that location for all selected tables, and updates all links in one step.

To change the path for a set of linked tables:

1. Open the database that contains links to tables.
2. On the **Tools** menu, point to **Add-ins (Database Utilities** in Access 2000 or newer), and then click **Linked Table Manager**.
3. Select the **Always Prompt For A New Location** check box.
4. Select the check box for the tables whose links you want to change, and then click **OK**.

5. In the **Select New Location of** <table name> dialog box, specify the new location, click **Open**, and then click **OK**.

25.1.4.4. MyODBC Programming Examples

With a suitable ODBC Manager and the my MyODBC driver installed, any programming language or environment that can support ODBC should be able to connect to a MySQL database through MyODBC.

This includes, but is certainly not limited to, Microsoft support languages (including Visual Basic, C# and interfaces such as ODBC.NET), Perl (through the DBI module, and the DBD::ODBC driver).

25.1.4.4.1. Using MyODBC with Visual Basic Using ADO, DAO and RDO

This section contains simple examples of the use of MySQL ODBC 3.51 Driver with ADO, DAO and RDO.

25.1.4.4.1.1. ADO: `rs.addNew`, `rs.delete`, and `rs.update`

The following ADO (ActiveX Data Objects) example creates a table `my_ado` and demonstrates the use of `rs.addNew`, `rs.delete`, and `rs.update`.

```
Private Sub myodbc_ado_Click()

Dim conn As ADODB.Connection
Dim rs As ADODB.Recordset
Dim fld As ADODB.Field
Dim sql As String

'connect to MySQL server using MySQL ODBC 3.51 Driver
Set conn = New ADODB.Connection
conn.ConnectionString = "DRIVER={MySQL ODBC 3.51 Driver};"_
& "SERVER=localhost;"_
& " DATABASE=test;"_
& "UID=venu;PWD=venu; OPTION=3"

conn.Open

'create table
conn.Execute "DROP TABLE IF EXISTS my_ado"
conn.Execute "CREATE TABLE my_ado(id int not null primary key, name varchar(20)," _
& "txt text, dt date, tm time, ts timestamp)"

'direct insert
conn.Execute "INSERT INTO my_ado(id,name,txt) values(1,100,'venu')"
conn.Execute "INSERT INTO my_ado(id,name,txt) values(2,200,'MySQL')"
conn.Execute "INSERT INTO my_ado(id,name,txt) values(3,300,'Delete')"

Set rs = New ADODB.Recordset
rs.CursorLocation = adUseServer

'fetch the initial table ..
rs.Open "SELECT * FROM my_ado", conn
Debug.Print rs.RecordCount
rs.MoveFirst
Debug.Print String(50, "-") & "Initial my_ado Result Set " & String(50, "-")
For Each fld In rs.Fields
Debug.Print fld.Name,
Next
Debug.Print

Do Until rs.EOF
For Each fld In rs.Fields
Debug.Print fld.Value,
Next
rs.MoveNext
Debug.Print
Loop
rs.Close

'rs insert
```

```

rs.Open "select * from my_ado", conn, adOpenDynamic, adLockOptimistic
rs.AddNew
rs!Name = "Monty"
rs!txt = "Insert row"
rs.Update
rs.Close

'rs update
rs.Open "SELECT * FROM my_ado"
rs!Name = "update"
rs!txt = "updated-row"
rs.Update
rs.Close

'rs update second time..
rs.Open "SELECT * FROM my_ado"
rs!Name = "update"
rs!txt = "updated-second-time"
rs.Update
rs.Close

'rs delete
rs.Open "SELECT * FROM my_ado"
rs.MoveNext
rs.MoveNext
rs.Delete
rs.Close

'fetch the updated table ..
rs.Open "SELECT * FROM my_ado", conn
Debug.Print rs.RecordCount
rs.MoveFirst
Debug.Print String(50, "-") & "Updated my_ado Result Set " & String(50, "-")
For Each fld In rs.Fields
Debug.Print fld.Name,
Next
Debug.Print

Do Until rs.EOF
For Each fld In rs.Fields
Debug.Print fld.Value,
Next
rs.MoveNext
Debug.Print
Loop
rs.Close
conn.Close
End Sub

```

25.1.4.4.1.2. DAO: `rs.addNew`, `rs.update`, and Scrolling

The following DAO (Data Access Objects) example creates a table `my_dao` and demonstrates the use of `rs.addNew`, `rs.update`, and result set scrolling.

```

Private Sub myodbc_dao_Click()

Dim ws As Workspace
Dim conn As Connection
Dim queryDef As queryDef
Dim str As String

'connect to MySQL using MySQL ODBC 3.51 Driver
Set ws = DBEngine.CreateWorkspace("", "venu", "venu", dbUseODBC)
str = "odbc;DRIVER={MySQL ODBC 3.51 Driver};"_
& "SERVER=localhost;"_
& " DATABASE=test;"_
& "UID=venu;PWD=venu; OPTION=3"
Set conn = ws.OpenConnection("test", dbDriverNoPrompt, False, str)

'Create table my_dao
Set queryDef = conn.CreateQueryDef("", "drop table if exists my_dao")
queryDef.Execute

Set queryDef = conn.CreateQueryDef("", "create table my_dao(Id INT AUTO_INCREMENT PRIMARY KEY, " _
& "Ts TIMESTAMP(14) NOT NULL, Name varchar(20), Id2 INT)")
queryDef.Execute

```

```

'Insert new records using rs.addNew
Set rs = conn.OpenRecordset("my_dao")
Dim i As Integer

For i = 10 To 15
rs.AddNew
rs!Name = "insert record" & i
rs!Id2 = i
rs.Update
Next i
rs.Close

'rs update..
Set rs = conn.OpenRecordset("my_dao")
rs.Edit
rs!Name = "updated-string"
rs.Update
rs.Close

'fetch the table back...
Set rs = conn.OpenRecordset("my_dao", dbOpenDynamic)
str = "Results:"
rs.MoveFirst
While Not rs.EOF
str = " " & rs!Id & " , " & rs!Name & " , " & rs!Ts & " , " & rs!Id2
Debug.Print "DATA:" & str
rs.MoveNext
Wend

'rs Scrolling
rs.MoveFirst
str = " FIRST ROW: " & rs!Id & " , " & rs!Name & " , " & rs!Ts & " , " & rs!Id2
Debug.Print str

rs.MoveLast
str = " LAST ROW: " & rs!Id & " , " & rs!Name & " , " & rs!Ts & " , " & rs!Id2
Debug.Print str

rs.MovePrevious
str = " LAST-1 ROW: " & rs!Id & " , " & rs!Name & " , " & rs!Ts & " , " & rs!Id2
Debug.Print str

'free all resources
rs.Close
queryDef.Close
conn.Close
ws.Close

End Sub

```

25.1.4.4.1.3. RDO: `rs.addNew` and `rs.update`

The following RDO (Remote Data Objects) example creates a table `my_rdo` and demonstrates the use of `rs.addNew` and `rs.update`.

```

Dim rs As rdoResultset
Dim cn As New rdoConnection
Dim cl As rdoColumn
Dim SQL As String

'cn.Connect = "DSN=test;"
cn.Connect = "DRIVER={MySQL ODBC 3.51 Driver};"_
& "SERVER=localhost;"_
& " DATABASE=test;"_
& "UID=venu;PWD=venu; OPTION=3"

cn.CursorDriver = rdUseOdbc
cn.EstablishConnection rdDriverPrompt

'drop table my_rdo
SQL = "drop table if exists my_rdo"
cn.Execute SQL, rdExecDirect

'create table my_rdo
SQL = "create table my_rdo(id int, name varchar(20))"
cn.Execute SQL, rdExecDirect

```

```

'insert - direct
SQL = "insert into my_rdo values (100,'venu')"
cn.Execute SQL, rdExecDirect

SQL = "insert into my_rdo values (200,'MySQL')"
cn.Execute SQL, rdExecDirect

'rs insert
SQL = "select * from my_rdo"
Set rs = cn.OpenResultset(SQL, rdOpenStatic, rdConcurRowVer, rdExecDirect)
rs.AddNew
rs!id = 300
rs!Name = "Insert1"
rs.Update
rs.Close

'rs insert
SQL = "select * from my_rdo"
Set rs = cn.OpenResultset(SQL, rdOpenStatic, rdConcurRowVer, rdExecDirect)
rs.AddNew
rs!id = 400
rs!Name = "Insert 2"
rs.Update
rs.Close

'rs update
SQL = "select * from my_rdo"
Set rs = cn.OpenResultset(SQL, rdOpenStatic, rdConcurRowVer, rdExecDirect)
rs.Edit
rs!id = 999
rs!Name = "updated"
rs.Update
rs.Close

'fetch back...
SQL = "select * from my_rdo"
Set rs = cn.OpenResultset(SQL, rdOpenStatic, rdConcurRowVer, rdExecDirect)
Do Until rs.EOF
For Each cl In rs.rdoColumns
Debug.Print cl.Value,
Next
rs.MoveNext
Debug.Print
Loop
Debug.Print "Row count="; rs.RowCount

'close
rs.Close
cn.Close

End Sub

```

25.1.4.4.2. Using MyODBC with .NET

This section contains simple examples that demonstrate the use of MyODBC drivers with ODBC.NET.

25.1.4.4.2.1. Using MyODBC with ODBC.NET and C# (C sharp)

The following sample creates a table `my_odbc_net` and demonstrates its use in C#.

```

/**
 * @sample      : mycon.cs
 * @purpose     : Demo sample for ODBC.NET using MyODBC
 * @author      : Venu, <myodbc@lists.mysql.com>
 *
 * (C) Copyright MySQL AB, 1995-2006
 *
 **/

/* build command
 *
 * csc /t:exe
 *      /out:mycon.exe mycon.cs
 *      /r:Microsoft.Data.Odbc.dll
 */

```

```
using Console = System.Console;
using Microsoft.Data.Odbc;

namespace myodbc3
{
    class mycon
    {
        static void Main(string[] args)
        {
            try
            {
                //Connection string for MyODBC 2.50
                /*string MyConString = "DRIVER={MySQL};" +
                    "SERVER=localhost;" +
                    "DATABASE=test;" +
                    "UID=venu;" +
                    "PASSWORD=venu;" +
                    "OPTION=3";
                */
                //Connection string for MyODBC 3.51
                string MyConString = "DRIVER={MySQL ODBC 3.51 Driver};" +
                    "SERVER=localhost;" +
                    "DATABASE=test;" +
                    "UID=venu;" +
                    "PASSWORD=venu;" +
                    "OPTION=3";

                //Connect to MySQL using MyODBC
                OdbcConnection MyConnection = new OdbcConnection(MyConString);
                MyConnection.Open();

                Console.WriteLine("\n !!! success, connected successfully !!!\n");

                //Display connection information
                Console.WriteLine("Connection Information:");
                Console.WriteLine("\tConnection String:" +
                    MyConnection.ConnectionString);
                Console.WriteLine("\tConnection Timeout:" +
                    MyConnection.ConnectionTimeout);
                Console.WriteLine("\tDatabase:" +
                    MyConnection.Database);
                Console.WriteLine("\tDataSource:" +
                    MyConnection.DataSource);
                Console.WriteLine("\tDriver:" +
                    MyConnection.Driver);
                Console.WriteLine("\tServerVersion:" +
                    MyConnection.ServerVersion);

                //Create a sample table
                OdbcCommand MyCommand =
                    new OdbcCommand("DROP TABLE IF EXISTS my_odbc_net",
                        MyConnection);
                MyCommand.ExecuteNonQuery();
                MyCommand.CommandText =
                    "CREATE TABLE my_odbc_net(id int, name varchar(20), idb bigint)";
                MyCommand.ExecuteNonQuery();

                //Insert
                MyCommand.CommandText =
                    "INSERT INTO my_odbc_net VALUES(10,'venu', 300)";
                Console.WriteLine("INSERT, Total rows affected:" +
                    MyCommand.ExecuteNonQuery());

                //Insert
                MyCommand.CommandText =
                    "INSERT INTO my_odbc_net VALUES(20,'mysql',400)";
                Console.WriteLine("INSERT, Total rows affected:" +
                    MyCommand.ExecuteNonQuery());

                //Insert
                MyCommand.CommandText =
                    "INSERT INTO my_odbc_net VALUES(20,'mysql',500)";
                Console.WriteLine("INSERT, Total rows affected:" +
                    MyCommand.ExecuteNonQuery());

                //Update
                MyCommand.CommandText =
                    "UPDATE my_odbc_net SET id=999 WHERE id=20";
                Console.WriteLine("Update, Total rows affected:" +
                    MyCommand.ExecuteNonQuery());
            }
        }
    }
}
```

```

'MyODBC 3.51 connection string
Dim MyConString As String = "DRIVER={MySQL ODBC 3.51 Driver};" & _

```

25.1.5. MyODBC Reference

This section provides reference material for the MyODBC API, showing supported functions and methods, supported MySQL column types and the corresponding native type in MyODBC, and the error codes returned by MyODBC when a fault occurs.

25.1.5.1. MyODBC API Reference

This section summarizes ODBC routines, categorized by functionality.

For the complete ODBC API reference, please refer to the ODBC Programmer's Reference at http://msdn.microsoft.com/library/en-us/odbc/hlm/odbcabout_this_manual.asp.

An application can call `SQLGetInfo` function to obtain conformance information about MyODBC. To obtain information about support for a specific function in the driver, an application can call `SQLGetFunctions`.

Note: For backward compatibility, the MyODBC 3.51 driver supports all deprecated functions.

The following tables list MyODBC API calls grouped by task:

Connecting to a data source:

Function name	MyODBC		Standard	Purpose
	2.50	3.51		
<code>SQLAllocHandle</code>	No	Yes	ISO 92	Obtains an environment, connection, statement, or descriptor handle.
<code>SQLConnect</code>	Yes	Yes	ISO 92	Connects to a specific driver by data source name, user ID, and password.
<code>SQLDriverConnect</code>	Yes	Yes	ODBC	Connects to a specific driver by connection string or requests that the Driver Manager and driver display connection dialog boxes for the user.
<code>SQLAllocEnv</code>	Yes	Yes	Deprecated	Obtains an environment handle allocated from driver.
<code>SQLAllocConnect</code>	Yes	Yes	Deprecated	Obtains a connection handle

Obtaining information about a driver and data source:

Function name	MyODBC		Standard	Purpose
	2.50	3.51		
<code>SQLDataSources</code>	No	No	ISO 92	Returns the list of available data sources, handled by the Driver Manager
<code>SQLDrivers</code>	No	No	ODBC	Returns the list of installed drivers and their attributes, handles by Driver Manager
<code>SQLGetInfo</code>	Yes	Yes	ISO 92	Returns information about a specific driver and data source.
<code>SQLGetFunctions</code>	Yes	Yes	ISO 92	Returns supported driver functions.
<code>SQLGetTypeInfo</code>	Yes	Yes	ISO 92	Returns information about supported data types.

Setting and retrieving driver attributes:

Function name	MyODBC		Standard	Purpose
	2.50	3.51		
SQLSetConnectAttr	No	Yes	ISO 92	Sets a connection attribute.
SQLGetConnectAttr	No	Yes	ISO 92	Returns the value of a connection attribute.
SQLSetConnectOption	Yes	Yes	Deprecated	Sets a connection option
SQLGetConnectOption	Yes	Yes	Deprecated	Returns the value of a connection option
SQLSetEnvAttr	No	Yes	ISO 92	Sets an environment attribute.
SQLGetEnvAttr	No	Yes	ISO 92	Returns the value of an environment attribute.
SQLSetStmtAttr	No	Yes	ISO 92	Sets a statement attribute.
SQLGetStmtAttr	No	Yes	ISO 92	Returns the value of a statement attribute.
SQLSetStmtOption	Yes	Yes	Deprecated	Sets a statement option
SQLGetStmtOption	Yes	Yes	Deprecated	Returns the value of a statement option

Preparing SQL requests:

Function name	MyODBC		Standard	Purpose
	2.50	3.51		
SQLAllocStmt	Yes	Yes	Deprecated	Allocates a statement handle
SQLPrepare	Yes	Yes	ISO 92	Prepares an SQL statement for later execution.
SQLBindParameter	Yes	Yes	ODBC	Assigns storage for a parameter in an SQL statement.
SQLGetCursorName	Yes	Yes	ISO 92	Returns the cursor name associated with a statement handle.
SQLSetCursorName	Yes	Yes	ISO 92	Specifies a cursor name.
SQLSetScrollOptions	Yes	Yes	ODBC	Sets options that control cursor behavior.

Submitting requests:

Function name	MyODBC		Standard	Purpose
	2.50	3.51		
SQLExecute	Yes	Yes	ISO 92	Executes a prepared statement.
SQLExecDirect	Yes	Yes	ISO 92	Executes a statement
SQLNativeSql	Yes	Yes	ODBC	Returns the text of an SQL statement as translated by the driver.
SQLDescribeParam	Yes	Yes	ODBC	Returns the description for a specific parameter in a statement.
SQLNumParams	Yes	Yes	ISO 92	Returns the number of parameters in a statement.
SQLParamData	Yes	Yes	ISO 92	Used in conjunction with SQLPutData to supply parameter data at execution time. (Useful for long data values.)

SQLPutData	Yes	Yes	ISO 92	Sends part or all of a data value for a parameter. (Useful for long data values.)
------------	-----	-----	--------	---

Retrieving results and information about results:

Function name	MyODBC		Standard	Purpose
	2.50	3.51		
SQLRowCount	Yes	Yes	ISO 92	Returns the number of rows affected by an insert, update, or delete request.
SQLNumResultCols	Yes	Yes	ISO 92	Returns the number of columns in the result set.
SQLDescribeCol	Yes	Yes	ISO 92	Describes a column in the result set.
SQLColAttribute	No	Yes	ISO 92	Describes attributes of a column in the result set.
SQLColAttributes	Yes	Yes	Deprecated	Describes attributes of a column in the result set.
SQLFetch	Yes	Yes	ISO 92	Returns multiple result rows.
SQLFetchScroll	No	Yes	ISO 92	Returns scrollable result rows.
SQLExtendedFetch	Yes	Yes	Deprecated	Returns scrollable result rows.
SQLSetPos	Yes	Yes	ODBC	Positions a cursor within a fetched block of data and allows an application to refresh data in the rowset or to update or delete data in the result set.
SQLBulkOperations	No	Yes	ODBC	Performs bulk insertions and bulk bookmark operations, including update, delete, and fetch by bookmark.

Retrieving error or diagnostic information:

Function name	MyODBC		Standard	Purpose
	2.50	3.51		
SQLError	Yes	Yes	Deprecated	Returns additional error or status information
SQLGetDiagField	Yes	Yes	ISO 92	Returns additional diagnostic information (a single field of the diagnostic data structure).
SQLGetDiagRec	Yes	Yes	ISO 92	Returns additional diagnostic information (multiple fields of the diagnostic data structure).

Obtaining information about the data source's system tables (catalog functions) item:

Function name	MyODBC		Standard	Purpose
	2.50	3.51		
SQLColumnPrivileges	Yes	Yes	ODBC	Returns a list of columns and associated privileges for one or more tables.
SQLColumns	Yes	Yes	X/Open	Returns the list of column names in specified tables.
SQLForeignKeys	Yes	Yes	ODBC	Returns a list of column names that make up foreign keys, if they exist for a specified table.
SQLPrimaryKeys	Yes	Yes	ODBC	Returns the list of column names that make up the primary key for a table.
SQLSpecialColumns	Yes	Yes	X/Open	Returns information about the optimal set of

				columns that uniquely identifies a row in a specified table, or the columns that are automatically updated when any value in the row is updated by a transaction.
<code>SQLStatistics</code>	Yes	Yes	ISO 92	Returns statistics about a single table and the list of indexes associated with the table.
<code>SQLTablePrivileges</code>	Yes	Yes	ODBC	Returns a list of tables and the privileges associated with each table.
<code>SQLTables</code>	Yes	Yes	X/Open	Returns the list of table names stored in a specific data source.

Performing transactions:

Function name	MyODBC		Standard	Purpose
	2.50	3.51		
<code>SQLTransact</code>	Yes	Yes	Deprecated	Commits or rolls back a transaction
<code>SQLEndTran</code>	No	Yes	ISO 92	Commits or rolls back a transaction.

Terminating a statement:

Function name	MyODBC		Standard	Purpose
	2.50	3.51		
<code>SQLFreeStmt</code>	Yes	Yes	ISO 92	Ends statement processing, discards pending results, and, optionally, frees all resources associated with the statement handle.
<code>SQLCloseCursor</code>	Yes	Yes	ISO 92	Closes a cursor that has been opened on a statement handle.
<code>SQLCancel</code>	Yes	Yes	ISO 92	Cancels an SQL statement.

Terminating a connection:

Function name	MyODBC		Standard	Purpose
	2.50	3.51		
<code>SQLDisconnect</code>	Yes	Yes	ISO 92	Closes the connection.
<code>SQLFreeHandle</code>	No	Yes	ISO 92	Releases an environment, connection, statement, or descriptor handle.
<code>SQLFreeConnect</code>	Yes	Yes	Deprecated	Releases connection handle
<code>SQLFreeEnv</code>	Yes	Yes	Deprecated	Releases an environment handle

25.1.5.2. MyODBC Data Types

The following table illustrates how driver maps the server data types to default SQL and C data types:

Native Value	SQL Type	C Type
<code>bit</code>	<code>SQL_BIT</code>	<code>SQL_C_BIT</code>
<code>tinyint</code>	<code>SQL_TINYINT</code>	<code>SQL_C_STINYINT</code>

Connectors

tinyint unsigned	SQL_TINYINT	SQL_C_UTINYINT
bigint	SQL_BIGINT	SQL_C_SBIGINT
bigint unsigned	SQL_BIGINT	SQL_C_UBIGINT
long varbinary	SQL_LONGVARBINARY	SQL_C_BINARY
blob	SQL_LONGVARBINARY	SQL_C_BINARY
longblob	SQL_LONGVARBINARY	SQL_C_BINARY
tinyblob	SQL_LONGVARBINARY	SQL_C_BINARY
mediumblob	SQL_LONGVARBINARY	SQL_C_BINARY
long varchar	SQL_LONGVARCHAR	SQL_C_CHAR
text	SQL_LONGVARCHAR	SQL_C_CHAR
mediumtext	SQL_LONGVARCHAR	SQL_C_CHAR
char	SQL_CHAR	SQL_C_CHAR
numeric	SQL_NUMERIC	SQL_C_CHAR
decimal	SQL_DECIMAL	SQL_C_CHAR
integer	SQL_INTEGER	SQL_C_SLONG
integer unsigned	SQL_INTEGER	SQL_C_ULONG
int	SQL_INTEGER	SQL_C_SLONG
int unsigned	SQL_INTEGER	SQL_C_ULONG
mediumint	SQL_INTEGER	SQL_C_SLONG
mediumint unsigned	SQL_INTEGER	SQL_C_ULONG
smallint	SQL_SMALLINT	SQL_C_SSHORT
smallint unsigned	SQL_SMALLINT	SQL_C_USHORT
real	SQL_FLOAT	SQL_C_DOUBLE
double	SQL_FLOAT	SQL_C_DOUBLE
float	SQL_REAL	SQL_C_FLOAT
double precision	SQL_DOUBLE	SQL_C_DOUBLE
date	SQL_DATE	SQL_C_DATE
time	SQL_TIME	SQL_C_TIME
year	SQL_SMALLINT	SQL_C_SHORT
datetime	SQL_TIMESTAMP	SQL_C_TIMESTAMP
timestamp	SQL_TIMESTAMP	SQL_C_TIMESTAMP
text	SQL_VARCHAR	SQL_C_CHAR
varchar	SQL_VARCHAR	SQL_C_CHAR
enum	SQL_VARCHAR	SQL_C_CHAR
set	SQL_VARCHAR	SQL_C_CHAR
bit	SQL_CHAR	SQL_C_CHAR
bool	SQL_CHAR	SQL_C_CHAR

25.1.5.3. MyODBC Error Codes

The following tables lists the error codes returned by the driver apart from the server errors.

Connectors

Native Code	SQLSTATE 2	SQLSTATE 3	Error Message
500	01000	01000	General warning
501	01004	01004	String data, right truncated
502	01S02	01S02	Option value changed
503	01S03	01S03	No rows updated/deleted
504	01S04	01S04	More than one row updated/deleted
505	01S06	01S06	Attempt to fetch before the result set returned the first row set
506	07001	07002	<code>SQLBindParameter</code> not used for all parameters
507	07005	07005	Prepared statement not a cursor-specification
508	07009	07009	Invalid descriptor index
509	08002	08002	Connection name in use
510	08003	08003	Connection does not exist
511	24000	24000	Invalid cursor state
512	25000	25000	Invalid transaction state
513	25S01	25S01	Transaction state unknown
514	34000	34000	Invalid cursor name
515	S1000	HY000	General driver defined error
516	S1001	HY001	Memory allocation error
517	S1002	HY002	Invalid column number
518	S1003	HY003	Invalid application buffer type
519	S1004	HY004	Invalid SQL data type
520	S1009	HY009	Invalid use of null pointer
521	S1010	HY010	Function sequence error
522	S1011	HY011	Attribute can not be set now
523	S1012	HY012	Invalid transaction operation code
524	S1013	HY013	Memory management error
525	S1015	HY015	No cursor name available
526	S1024	HY024	Invalid attribute value
527	S1090	HY090	Invalid string or buffer length
528	S1091	HY091	Invalid descriptor field identifier
529	S1092	HY092	Invalid attribute/option identifier
530	S1093	HY093	Invalid parameter number
531	S1095	HY095	Function type out of range
532	S1106	HY106	Fetch type out of range
533	S1117	HY117	Row value out of range
534	S1109	HY109	Invalid cursor position
535	S1C00	HYC00	Optional feature not implemented
0	21S01	21S01	Column count does not match value count
0	23000	23000	Integrity constraint violation
0	42000	42000	Syntax error or access violation

0	42S02	42S02	Base table or view not found
0	42S12	42S12	Index not found
0	42S21	42S21	Column already exists
0	42S22	42S22	Column not found
0	08S01	08S01	Communication link failure

25.1.6. MyODBC Notes and Tips

Here are some common notes and tips for using MyODBC within different environments, applications and tools. The notes provided here are based on the experiences of MyODBC developers and users.

25.1.6.1. MyODBC General Functionality

This section provides help with common queries and areas of functionality in MySQL and how to use them with MyODBC.

25.1.6.1.1. Obtaining Auto-Increment Values

Obtaining the value of column that uses `AUTO_INCREMENT` after an `INSERT` statement can be achieved in a number of different ways. To obtain the value immediately after an `INSERT`, use a `SELECT` query with the `LAST_INSERT_ID()` function.

For example, using MyODBC you would execute two separate statements, the `INSERT` statement and the `SELECT` query to obtain the auto-increment value.

```
INSERT INTO tbl (auto,text) VALUES(NULL,'text');
SELECT LAST_INSERT_ID();
```

If you do not require the value within your application, but do require the value as part of another `INSERT`, the entire process can be handled by executing the following statements:

```
INSERT INTO tbl (auto,text) VALUES(NULL,'text');
INSERT INTO tbl2 (id,text) VALUES(LAST_INSERT_ID(),'text');
```

Certain ODBC applications (including Delphi and Access) may have trouble obtaining the auto-increment value using the previous examples. In this case, try the following statement as an alternative:

```
SELECT * FROM tbl WHERE auto IS NULL;
```

See [Section 24.2.13.3, “How to Get the Unique ID for the Last Inserted Row”](#).

25.1.6.1.2. Dynamic Cursor Support

Support for the `dynamic cursor` is provided in MyODBC 3.51, but dynamic cursors are not enabled by default. You can enable this function within Windows by selecting the `Enable Dynamic Cursor` checkbox within the ODBC Data Source Administrator.

On other platforms, you can enable the dynamic cursor by adding `32` to the `OPTION` value when creating the DSN.

25.1.6.1.3. MyODBC Performance

The MyODBC driver has been optimized to provide very fast performance. If you experience problems with the performance of MyODBC, or notice a large amount of disk activity for simple queries, there are

a number of aspects you should check:

- Ensure that **ODBC Tracing** is not enabled. With tracing enabled, a lot of information is recorded in the tracing file by the ODBC Manager. You can check, and disable, tracing within Windows using the **Tracing** panel of the ODBC Data Source Administrator. Within Mac OS X, check the **Tracing** panel of ODBC Administrator. See [Section 25.1.3.8, “Getting an ODBC Trace File”](#).
- Make sure you are using the standard version of the driver, and not the debug version. The debug version includes additional checks and reporting measures.
- Disable the MyODBC driver trace and query logs. These options are enabled for each DSN, so make sure to examine only the DSN that you are using in your application. Within Windows, you can disable the MyODBC and query logs by modifying the DSN configuration. Within Mac OS X and Unix, ensure that the driver trace (option value 4) and query logging (option value 524288) are not enabled.

25.1.6.1.4. Setting ODBC Query Timeout in Windows

For more information on how to set the query timeout on Microsoft Windows when executing queries through an ODBC connection, read the Microsoft knowledgebase document at <http://support.microsoft.com/default.aspx?scid=kb%3Ben-us%3B153756>.

25.1.6.2. MyODBC Application Specific Tips

Most programs should work with MyODBC, but for each of those listed here, there are specific notes and tips to improve or enhance the way you work with MyODBC and these applications.

With all applications you should ensure that you are using the latest MyODBC drivers, ODBC Manager and any supporting libraries and interfaces used by your application. For example, on Windows, using the latest version of Microsoft Data Access Components (MDAC) will improve the compatibility with ODBC in general, and with the MyODBC driver.

25.1.6.2.1. Using MyODBC with Microsoft Applications

The majority of Microsoft applications have been tested with MyODBC, including Microsoft Office, Microsoft Access and the various programming languages supported within ASP and Microsoft Visual Studio.

If you have problem with MyODBC and your program also works with OLEDB, you should try the OLEDB driver.

25.1.6.2.1.1. Microsoft Access

To improve the integration between Microsoft Access and MySQL through MyODBC:

- For all versions of Access, you should enable the MyODBC **Return matching rows** option. For Access 2.0, you should additionally enable the **Simulate ODBC 1.0** option.
- You should have a **TIMESTAMP** column in all tables that you want to be able to update. For maximum portability, don't use a length specification in the column declaration (which is unsupported within MySQL in versions earlier than 4.1).
- You should have a primary key in each MySQL table you want to use with Access. If not, new or updated rows may show up as **#DELETED#**.

- Use only `DOUBLE` float fields. Access fails when comparing with single-precision floats. The symptom usually is that new or updated rows may show up as `#DELETED#` or that you can't find or update rows.
- If you are using MyODBC to link to a table that has a `BIGINT` column, the results are displayed as `#DELETED#`. The work around solution is:
 - Have one more dummy column with `TIMESTAMP` as the data type.
 - Select the `Change BIGINT columns to INT` option in the connection dialog in ODBC DSN Administrator.
 - Delete the table link from Access and re-create it.

Old records may still display as `#DELETED#`, but newly added/updated records are displayed properly.

- If you still get the error `Another user has changed your data` after adding a `TIMESTAMP` column, the following trick may help you:

Don't use a `table` data sheet view. Instead, create a form with the fields you want, and use that `form` data sheet view. You should set the `DefaultValue` property for the `TIMESTAMP` column to `NOW()`. It may be a good idea to hide the `TIMESTAMP` column from view so your users are not confused.

- In some cases, Access may generate SQL statements that MySQL can't understand. You can fix this by selecting "`Query | SQLSpecific | Pass-Through`" from the Access menu.
- On Windows NT, Access reports `BLOB` columns as `OLE OBJECTS`. If you want to have `MEMO` columns instead, you should change `BLOB` columns to `TEXT` with `ALTER TABLE`.
- Access can't always handle the MySQL `DATE` column properly. If you have a problem with these, change the columns to `DATETIME`.
- If you have in Access a column defined as `BYTE`, Access tries to export this as `TINYINT` instead of `TINYINT UNSIGNED`. This gives you problems if you have values larger than 127 in the column.
- If you have very large (long) tables in Access, it might take a very long time to open them. Or you might run low on virtual memory and eventually get an `ODBC Query Failed` error and the table cannot open. To deal with this, select the following options:
 - Return Matching Rows (2)
 - Allow BIG Results (8).

These add up to a value of 10 (`OPTION=10`).

Some external articles and tips that may be useful when using Access, ODBC and MyODBC:

- For a list of tools that can be used with Access and ODBC data sources, refer to [converters](#)
[http://www.mysql.com/portal/software/convertors/] section for list of available tools.

25.1.6.2.1.2. Microsoft Excel and Column Types

If you have problems importing data into Microsoft Excel, particularly numerical, date, and time values, this is probably because of a bug in Excel, where the column type of the source data is used to determine the data type when that data is inserted into a cell within the worksheet. The result is that Excel incorrectly identifies the content and this affects both the display format and the data when it is used within calculations.

To address this issue, use the `CONCAT()` function in your queries. The use of `CONCAT()` forces Excel to treat the value as a string, which Excel will then parse and usually correctly identify the embedded information.

However, even with this option, some data may be incorrectly formatted, even though the source data remains unchanged. Use the `Format Cells` option within Excel to change the format of the displayed information.

25.1.6.2.1.3. Microsoft Visual Basic

To be able to update a table, you must define a primary key for the table.

Visual Basic with ADO can't handle big integers. This means that some queries like `SHOW PROCESSLIST` do not work properly. The fix is to use `OPTION=16384` in the ODBC connect string or to select the `Change BIGINT columns to INT` option in the MyODBC connect screen. You may also want to select the `Return matching rows` option.

25.1.6.2.1.4. Microsoft Visual InterDev

If you have a `BIGINT` in your result, you may get the error `[Microsoft][ODBC Driver Manager] Driver does not support this parameter`. Try selecting the `Change BIGINT columns to INT` option in the MyODBC connect screen.

25.1.6.2.1.5. Visual Objects

You should select the `Don't optimize column widths` option.

25.1.6.2.1.6. Microsoft ADO

When you are coding with the ADO API and MyODBC, you need to pay attention to some default properties that aren't supported by the MySQL server. For example, using the `CursorLocation Property` as `adUseServer` returns a result of `-1` for the `RecordCount Property`. To have the right value, you need to set this property to `adUseClient`, as shown in the VB code here:

```
Dim myconn As New ADOConnection
Dim myrs As New Recordset
Dim mySQL As String
Dim myrows As Long

myconn.Open "DSN=MyODBCsample"
mySQL = "SELECT * from user"
myrs.Source = mySQL
Set myrs.ActiveConnection = myconn
```

```
myrs.CursorLocation = adUseClient
myrs.Open
myrows = myrs.RecordCount

myrs.Close
myconn.Close
```

Another workaround is to use a `SELECT COUNT(*)` statement for a similar query to get the correct row count.

To find the number of rows affected by a specific SQL statement in ADO, use the `RecordsAffected` property in the ADO execute method. For more information on the usage of execute method, refer to <http://msdn.microsoft.com/library/default.asp?url=/library/en-us/ado270/htm/mdmthcnexecute.asp>.

For information, see [ActiveX Data Objects\(ADO\) Frequently Asked Questions](http://support.microsoft.com/default.aspx?scid=kb;EN-US;q183606) [http://support.microsoft.com/default.aspx?scid=kb;EN-US;q183606].

25.1.6.2.1.7. Using MyODBC with Active Server Pages (ASP)

You should select the `Return matching rows` option in the DSN.

For more information about how to access MySQL via ASP using MyODBC, refer to the following articles:

- [Using MyODBC To Access Your MySQL Database Via ASP](http://www.devarticles.com/c/a/ASP/Using-MyODBC-To-Access-Your-MySQL-Database-Via-ASP/) [http://www.devarticles.com/c/a/ASP/Using-MyODBC-To-Access-Your-MySQL-Database-Via-ASP/]
- [ASP and MySQL at DWAM.NT](http://www.dwam.net/mysql/asp_myodbc.asp) [http://www.dwam.net/mysql/asp_myodbc.asp]

A Frequently Asked Questions list for ASP can be found at <http://support.microsoft.com/default.aspx?scid=/Support/ActiveServer/faq/data/adofaq.asp>.

25.1.6.2.1.8. Using MyODBC with Visual Basic (ADO, DAO and RDO) and ASP

Some articles that may help with Visual Basic and ASP:

- [MySQL BLOB columns and Visual Basic 6](http://dev.mysql.com/tech-resources/articles/vb-blob-handling.html) [http://dev.mysql.com/tech-resources/articles/vb-blob-handling.html] by Mike Hillyer (<mike@openwin.org>).
- [How to map Visual basic data type to MySQL types](http://dev.mysql.com/tech-resources/articles/visual-basic-datatypes.html) [http://dev.mysql.com/tech-resources/articles/visual-basic-datatypes.html] by Mike Hillyer (<mike@openwin.org>).

25.1.6.2.2. Using MyODBC with Borland Applications

With all Borland applications where the Borland Database Engine (BDE) is used, follow these steps to improve compatibility:

- Update to BDE 3.2 or newer.
- Enable the `Don't optimize column widths` option in the DSN.

- Enabled the `Return matching rows` option in the DSN.

25.1.6.2.2.1. Using MyODBC with Borland Builder 4

When you start a query, you can use the `Active` property or the `Open` method. Note that `Active` starts by automatically issuing a `SELECT * FROM ...` query. That may not be a good thing if your tables are large.

25.1.6.2.2.2. Using MyODBC with Delphi

Also, here is some potentially useful Delphi code that sets up both an ODBC entry and a BDE entry for MyODBC. The BDE entry requires a BDE Alias Editor that is free at a Delphi Super Page near you. (Thanks to Bryan Brunton <bryan@flesherfab.com> for this):

```
fReg:= TRegistry.Create;
fReg.OpenKey('\Software\ODBC\ODBC.INI\DocumentsFab', True);
fReg.WriteString('Database', 'Documents');
fReg.WriteString('Description', '');
fReg.WriteString('Driver', 'C:\WINNT\System32\myodbc.dll');
fReg.WriteString('Flag', '1');
fReg.WriteString('Password', '');
fReg.WriteString('Port', '');
fReg.WriteString('Server', 'xmark');
fReg.WriteString('User', 'winuser');
fReg.OpenKey('\Software\ODBC\ODBC.INI\ODBC Data Sources', True);
fReg.WriteString('DocumentsFab', 'MySQL');
fReg.CloseKey;
fReg.Free;

Memol.Lines.Add('DATABASE NAME=');
Memol.Lines.Add('USER NAME=');
Memol.Lines.Add('ODBC DSN=DocumentsFab');
Memol.Lines.Add('OPEN MODE=READ/WRITE');
Memol.Lines.Add('BATCH COUNT=200');
Memol.Lines.Add('LANGDRIVER=');
Memol.Lines.Add('MAX ROWS=-1');
Memol.Lines.Add('SCHEMA CACHE DIR=');
Memol.Lines.Add('SCHEMA CACHE SIZE=8');
Memol.Lines.Add('SCHEMA CACHE TIME=-1');
Memol.Lines.Add('SQLPASSTHRU MODE=SHARED AUTOCOMMIT');
Memol.Lines.Add('SQLQRYMODE=');
Memol.Lines.Add('ENABLE SCHEMA CACHE=FALSE');
Memol.Lines.Add('ENABLE BCD=FALSE');
Memol.Lines.Add('ROWSET SIZE=20');
Memol.Lines.Add('BLOBS TO CACHE=64');
Memol.Lines.Add('BLOB SIZE=32');

AliasEditor.Add('DocumentsFab', 'MySQL', Memol.Lines);
```

25.1.6.2.2.3. Using MyODBC with C++ Builder

Tested with BDE 3.0. The only known problem is that when the table schema changes, query fields are not updated. BDE, however, does not seem to recognize primary keys, only the index named `PRIMARY`, although this has not been a problem.

25.1.6.2.3. Using MyODBC with ColdFusion

The following information is taken from the ColdFusion documentation:

Use the following information to configure ColdFusion Server for Linux to use the `unixODBC` driver with MyODBC for MySQL data sources. Allaire has verified that MyODBC 2.50.26 works with MySQL 3.22.27 and ColdFusion for Linux. (Any newer version should also work.) You can download MyODBC at <http://dev.mysql.com/downloads/connector/odbc/>.

ColdFusion version 4.5.1 allows you to use the ColdFusion Administrator to add the MySQL data source. However, the driver is not included with ColdFusion version 4.5.1. Before the MySQL driver appears in

the ODBC data sources drop-down list, you must build and copy the MyODBC driver to /
[opt/coldfusion/lib/libmyodbc.so](#).

The Contrib directory contains the program [mydsn-xxx.zip](#) which allows you to build and remove the DSN registry file for the MyODBC driver on ColdFusion applications.

For more information and guides on using ColdFusion and MyODBC, see the following external sites:

- Refer to [MySQL ColdFusion unixODBC MyODBC and Solaris - how to succeed](#) [<http://dbforums.com/showthread.php?threadid=174934>]
- ColdFusion (on Solaris and NT with service pack 5), [How-to: MySQL and ColdFusion](#) [<http://www.njwtech.net/addons/coldfusion/mysql.html>].
- [Troubleshooting Data Sources and Database Connectivity for Unix Platforms](#) [<http://www.macromedia.com/v1/handlers/index.cfm?ID=11328&Method=Full&PageCall=/support/index.cfm>].

25.1.6.2.4. Using MyODBC with OpenOffice

Open Office (<http://www.openoffice.org>) [How-to: MySQL + OpenOffice](#) [http://dba.openoffice.org/proposals/MySQL_OOo.html]. [How-to: OpenOffice + MyODBC + unixODBC](#) [<http://www.unixodbc.org/doc/OOoMySQL.pdf>].

25.1.6.2.5. Using MyODBC with Sambar Server

Sambar Server (<http://www.sambarserver.info>) [How-to: MyODBC + SambarServer + MySQL](#) [<http://www.sambarserver.info/article.php?sid=66>].

25.1.6.2.6. Using MyODBC with Pervasive Software DataJunction

You have to change it to output `VARCHAR` rather than `ENUM`, as it exports the latter in a manner that causes MySQL problems.

25.1.6.2.7. Using MyODBC with SunSystems Vision

You should select the `Return matching rows` option.

25.1.6.3. MyODBC Errors and Resolutions

The following section details some common errors and their suggested fix or alternative solution. If you are still experiencing problems, use the MyODBC mailing list; see [Section 25.1.7.1, “MyODBC Community Support”](#).

Many problems can be resolved by upgrading your MyODBC drivers to the latest available release. On Windows, you should also make sure that you have the latest versions of the Microsoft Data Access Components (MDAC) installed.

Questions

- [26.1.6.3.1](#): Are MyODBC 2.50 applications compatible with MyODBC 3.51?
- [26.1.6.3.2](#): I have installed MyODBC on Windows XP x64 Edition or Windows Server 2003 R2 x64. The installation completed successfully, but the MyODBC driver does not appear in [ODBC Data Source Administrator](#).

- [26.1.6.3.3](#): When connecting or using the `Test` button in `ODBC Data Source Administrator` I get error 10061 (Cannot connect to server)
- [26.1.6.3.4](#): The following error is reported when using transactions: `Transactions are not enabled`
- [26.1.6.3.5](#): The following error is reported when I submit a query: `Cursor not found`
- [26.1.6.3.6](#): Access reports records as `#DELETED#` when inserting or updating records in linked tables.
- [26.1.6.3.7](#): How do I handle Write Conflicts or Row Location errors?
- [26.1.6.3.8](#): Exporting data from Access 97 to MySQL reports a `Syntax Error`.
- [26.1.6.3.9](#): Exporting data from Microsoft DTS to MySQL reports a `Syntax Error`.
- [26.1.6.3.10](#): Using ODBC.NET with MyODBC, while fetching empty string (0 length), it starts giving the `SQL_NO_DATA` exception.
- [26.1.6.3.11](#): Using `SELECT COUNT(*) FROM tbl_name` within Visual Basic and ASP returns an error.
- [26.1.6.3.12](#): Using the `AppendChunk()` or `GetChunk()` ADO methods, the `Multiple-step operation generated errors`. Check each `status value` error is returned.
- [26.1.6.3.13](#): Access Returns `Another user had modified the record that you have modified` while editing records on a Linked Table.

Questions and Answers

26.1.6.3.1: Are MyODBC 2.50 applications compatible with MyODBC 3.51?

Applications based on MyODBC 2.50 should work fine with MyODBC 3.51 and later versions. If you find something is not working with the latest version of MyODBC which previously worked under an earlier version, please file a bug report. See [Section 25.1.7.2](#), “How to Report MyODBC Problems or Bugs”.

26.1.6.3.2: I have installed MyODBC on Windows XP x64 Edition or Windows Server 2003 R2 x64. The installation completed successfully, but the MyODBC driver does not appear in ODBC Data Source Administrator.

This is not a bug, but is related to the way Windows x64 editions operate with the ODBC driver. On Windows x64 editions, the MyODBC driver is installed in the `%SystemRoot%\SysWOW64` folder. However, the default `ODBC Data Source Administrator` that is available through the `Administrative Tools` or `Control Panel` in Windows x64 Editions is located in the `%SystemRoot%\system32` folder, and only searches this folder for ODBC drivers.

On Windows x64 editions, you should use the ODBC administration tool located at `%SystemRoot%\SysWOW64\odbcad32.exe`, this will correctly locate the installed MyODBC drivers and enable you to create a MyODBC DSN.

This issue was originally reported as [Bug#20301](http://bugs.mysql.com/20301) [<http://bugs.mysql.com/20301>].

26.1.6.3.3: When connecting or using the Test button in ODBC Data Source Administrator I get error 10061 (Cannot connect to server)

This error can be raised by a number of different issues, including server problems, network problems,

and firewall and port blocking problems. For more information, see [Section A.2.2, “Can't connect to \[local\] MySQL server”](#).

26.1.6.3.4: The following error is reported when using transactions: Transactions are not enabled

This error indicates that you are trying to use transactions with a MySQL table that does not support transactions. Transactions are supported within MySQL when using the [InnoDB](#) database engine.

You should check the following before continuing:

- Verify that your MySQL server supports a transactional database engine. Use `SHOW ENGINES` to obtain a list of the available engine types.
- Verify that the tables you are updating use a transaction database engine.
- Ensure that you have not enabled the `disable transactions` option in your DSN.

26.1.6.3.5: The following error is reported when I submit a query: Cursor not found

This occurs because the application is using the old MyODBC 2.50 version, and it did not set the cursor name explicitly through `SQLSetCursorName`. The fix is to upgrade to MyODBC 3.51 version.

26.1.6.3.6: Access reports records as #DELETED# when inserting or updating records in linked tables.

If the inserted or updated records are shown as `#DELETED#` in the access, then:

- If you are using Access 2000, you should get and install the newest (version 2.6 or higher) Microsoft MDAC ([Microsoft Data Access Components](#)) from <http://www.microsoft.com/data/>. This fixes a bug in Access that when you export data to MySQL, the table and column names aren't specified. Another way to work around this bug is to upgrade to MyODBC 2.50.33 or higher and MySQL 3.23.x or higher, which together provide a workaround for the problem.

You should also get and apply the Microsoft Jet 4.0 Service Pack 5 (SP5) which can be found at <http://support.microsoft.com/default.aspx?scid=kb;EN-US;q239114>. This fixes some cases where columns are marked as `#DELETED#` in Access.

Note: If you are using MySQL 3.22, you must apply the MDAC patch and use MyODBC 2.50.32 or 2.50.34 and up to work around this problem.

- For all versions of Access, you should enable the MyODBC `Return matching rows` option. For Access 2.0, you should additionally enable the `Simulate ODBC 1.0` option.
- You should have a timestamp in all tables that you want to be able to update..
- You should have a primary key in the table. If not, new or updated rows may show up as `#DELETED#`.
- Use only `DOUBLE` float fields. Access fails when comparing with single-precision floats. The symptom usually is that new or updated rows may show up as `#DELETED#` or that you can't find or update rows.
- If you are using MyODBC to link to a table that has a `BIGINT` column, the results are displayed as `#DELETED`. The work around solution is:

- Have one more dummy column with `TIMESTAMP` as the data type.
- Select the `Change BIGINT columns to INT` option in the connection dialog in ODBC DSN Administrator.
- Delete the table link from Access and re-create it.

Old records still display as `#DELETED#`, but newly added/updated records are displayed properly.

26.1.6.3.7: How do I handle Write Conflicts or Row Location errors?

If you see the following errors, select the `Return Matching Rows` option in the DSN configuration dialog, or specify `OPTION=2`, as the connection parameter:

```
Write Conflict. Another user has changed your data.  
Row cannot be located for updating. Some values may have been changed  
since it was last read.
```

26.1.6.3.8: Exporting data from Access 97 to MySQL reports a `Syntax Error`.

This error is specific to Access 97 and versions of MyODBC earlier than 3.51.02. Update to the latest version of the MyODBC driver to resolve this problem.

26.1.6.3.9: Exporting data from Microsoft DTS to MySQL reports a `Syntax Error`.

This error occurs only with MySQL tables using the `TEXT` or `VARCHAR` data types. You can fix this error by upgrading your MyODBC driver to version 3.51.02 or higher.

26.1.6.3.10: Using ODBC.NET with MyODBC, while fetching empty string (0 length), it starts giving the `SQL_NO_DATA` exception.

You can get the patch that addresses this problem from <http://support.microsoft.com/default.aspx?scid=kb;EN-US;q319243>.

26.1.6.3.11: Using `SELECT COUNT(*) FROM tbl_name` within Visual Basic and ASP returns an error.

This error occurs because the `COUNT(*)` expression is returning a `BIGINT`, and ADO can't make sense of a number this big. Select the `Change BIGINT columns to INT` option (option value 16384).

26.1.6.3.12: Using the `AppendChunk()` or `GetChunk()` ADO methods, the `Multiple-step operation generated errors. Check each status value error is returned`.

The `GetChunk()` and `AppendChunk()` methods from ADO doesn't work as expected when the cursor location is specified as `adUseServer`. On the other hand, you can overcome this error by using `adUseClient`.

A simple example can be found from http://www.dwam.net/iishelp/ado/docs/adomth02_4.htm

26.1.6.3.13: Access Returns `Another user had modified the record that you have modified while editing records on a Linked Table`.

In most cases, this can be solved by doing one of the following things:

- Add a primary key for the table if one doesn't exist.

- Add a timestamp column if one doesn't exist.
- Only use double-precision float fields. Some programs may fail when they compare single-precision floats.

If these strategies don't help, you should start by making a log file from the ODBC manager (the log you get when requesting logs from ODBCADMIN) and a MyODBC log to help you figure out why things go wrong. For instructions, see [Section 25.1.3.8, “Getting an ODBC Trace File”](#).

25.1.7. MyODBC Support

There are many different places where you can get support for using MyODBC. You should always try the MyODBC Mailing List or MyODBC Forum. See [Section 25.1.7.1, “MyODBC Community Support”](#), for help before reporting a specific bug or issue to MySQL.

25.1.7.1. MyODBC Community Support

MySQL AB provides assistance to the user community by means of its mailing lists. For MyODBC-related issues, you can get help from experienced users by using the `<myodbc@lists.mysql.com>` mailing list. Archives are available online at <http://lists.mysql.com/myodbc>.

For information about subscribing to MySQL mailing lists or to browse list archives, visit <http://lists.mysql.com/>. See [Section 1.7.1, “MySQL Mailing Lists”](#).

Community support from experienced users is also available through the [MyODBC Forum](#) [<http://forums.mysql.com/list.php?37>]. You may also find help from other users in the other MySQL Forums, located at <http://forums.mysql.com>. See [Section 1.7.2, “MySQL Community Support at the MySQL Forums”](#).

25.1.7.2. How to Report MyODBC Problems or Bugs

If you encounter difficulties or problems with MyODBC, you should start by making a log file from the [ODBC Manager](#) (the log you get when requesting logs from `ODBC ADMIN`) and MyODBC. The procedure for doing this is described in [Section 25.1.3.8, “Getting an ODBC Trace File”](#).

Check the MyODBC trace file to find out what could be wrong. You should be able to determine what statements were issued by searching for the string `>mysql_real_query` in the `myodbc.log` file.

You should also try issuing the statements from the `mysql` client program or from `admindemo`. This helps you determine whether the error is in MyODBC or MySQL.

If you find out something is wrong, please only send the relevant rows (maximum 40 rows) to the `myo-
dbc` mailing list. See [Section 1.7.1, “MySQL Mailing Lists”](#). Please never send the whole MyODBC or ODBC log file!

You should ideally include the following information with the email:

- Operating system and version
- MyODBC version
- ODBC Driver Manager type and version
- MySQL server version
- ODBC trace from Driver Manager

- MyODBC log file from MyODBC driver
- Simple reproducible sample

Remember that the more information you can supply to us, the more likely it is that we can fix the problem!

Also, before posting the bug, check the MyODBC mailing list archive at <http://lists.mysql.com/myodbc>.

If you are unable to find out what's wrong, the last option is to create an archive in `tar` or Zip format that contains a MyODBC trace file, the ODBC log file, and a `README` file that explains the problem. You can send this to <ftp://ftp.mysql.com/pub/mysql/upload/>. Only MySQL engineers have access to the files you upload, and we are very discreet with the data.

If you can create a program that also demonstrates the problem, please include it in the archive as well.

If the program works with another SQL server, you should include an ODBC log file where you perform exactly the same SQL statements so that we can compare the results between the two systems.

Remember that the more information you can supply to us, the more likely it is that we can fix the problem.

25.1.7.3. How to Submit a MyODBC Patch

You can send a patch or suggest a better solution for any existing code or problems by sending a mail message to [<myodbc@lists.mysql.com>](mailto:myodbc@lists.mysql.com).

25.1.7.4. MyODBC Change History

The MyODBC Change History (Changelog) is located with the main Changelog for MySQL. See [Section D.2, “MySQL Connector/ODBC \(MyODBC\) Change History”](#).

25.1.7.5. Credits

These are the developers that have worked on the MyODBC and MyODBC 3.51 Drivers from MySQL AB.

- Michael (Monty) Widenius
- Venu Anuganti
- Peter Harvey

25.2. Connector/NET

Connector/NET enables developers to easily create .NET applications that require secure, high-performance data connectivity with MySQL. It implements the required ADO.NET interfaces and integrates into ADO.NET aware tools. Developers can build applications using their choice of .NET languages. Connector/NET is a fully managed ADO.NET driver written in 100% pure C#.

Connector/NET includes full support for:

- MySQL 5.0 features (such as stored procedures)

- MySQL 4.1 features (server-side prepared statements, Unicode, and shared memory access, and so forth)
- Large-packet support for sending and receiving rows and BLOBs up to 2 gigabytes in size.
- Protocol compression which allows for compressing the data stream between the client and server.
- Support for connecting using TCP/IP sockets, named pipes, or shared memory on Windows.
- Support for connecting using TCP/IP sockets or Unix sockets on Unix.
- Support for the Open Source Mono framework developed by Novell.
- Fully managed, does not utilize the MySQL client library.

This document is intended as a user's guide to Connector/NET and includes a full syntax reference. Syntax information is also included within the [Documentation.chm](#) file included with the Connector/NET distribution.

25.2.1. Connector/NET Versions

There is currently one version of the Connector/NET available:

- Connector/NET 1.0 includes support for MySQL 4.0, and MySQL 5.0 features, and full compatibility with the ADO.NET driver interface.

25.2.2. How to install Connector/NET

Connector/NET runs on any platform that supports the .NET framework. The .NET framework is primarily supported on recent versions of Microsoft Windows, and is supported on Linux through the Open Source Mono framework (see <http://www.mono-project.com>).

Connector/NET is available for download from <http://dev.mysql.com/downloads/connector/net/1.0.html>.

25.2.2.1. Installing Connector/NET on Windows

On Windows, installation is supported either through a binary installation process or by downloading a Zip file with the Connector/NET components.

Before installing, you should ensure that your system is up to date, including installing the latest version of the .NET Framework.

25.2.2.1.1. Installing Connector/NET using the Installer

Using the installer is the most straightforward method of installing Connector/NET on Windows and the installed components include the source code, test code and full reference documentation.

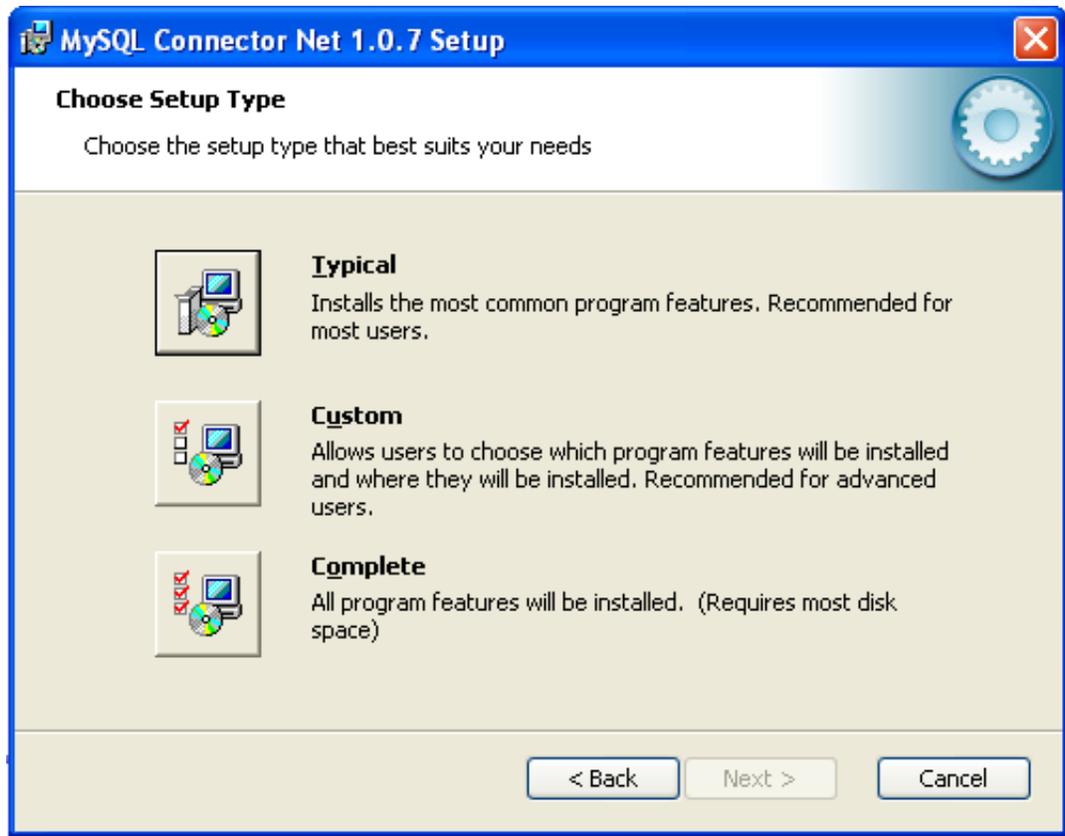

Connector/NET is installed through the use of a Windows Installer ([.msi](#)) installation package, which can be used to install Connector/NET on all Windows operating systems. The MSI package is contained within a ZIP archive named [mysql-connector-net-version.zip](#), where *version* indicates the Connector/NET version.

To install Connector/NET:

1. Double click on the MSI installer file extracted from the Zip you downloaded. Click [Next](#) to start the installation.

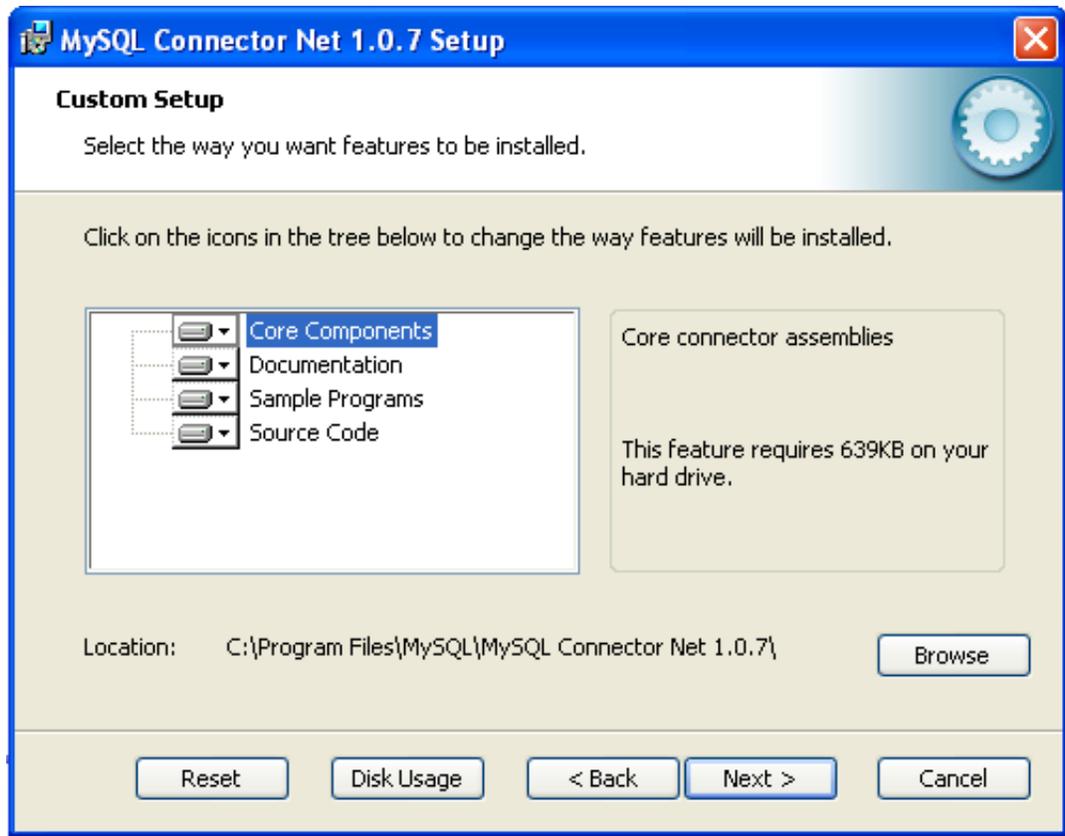

2. You must choose the type of installation that you want to perform.

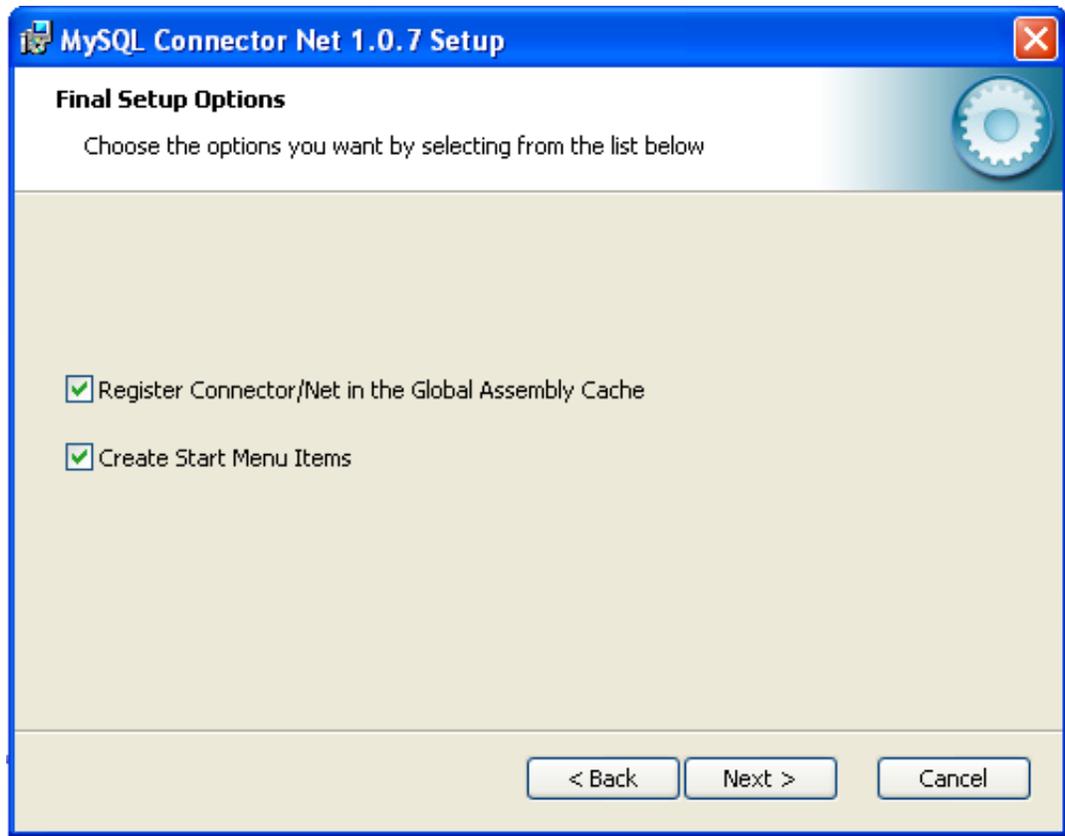

For most situations, the Typical installation will be suitable. Click the [Typical](#) button and proceed to Step 5. A Complete installation installs all the available files. To conduct a Complete installation, click the [Complete](#) button and proceed to step 5. If you want to customize your installation, including choosing the components to install and some installation options, click the [Custom](#) button and proceed to Step 3.

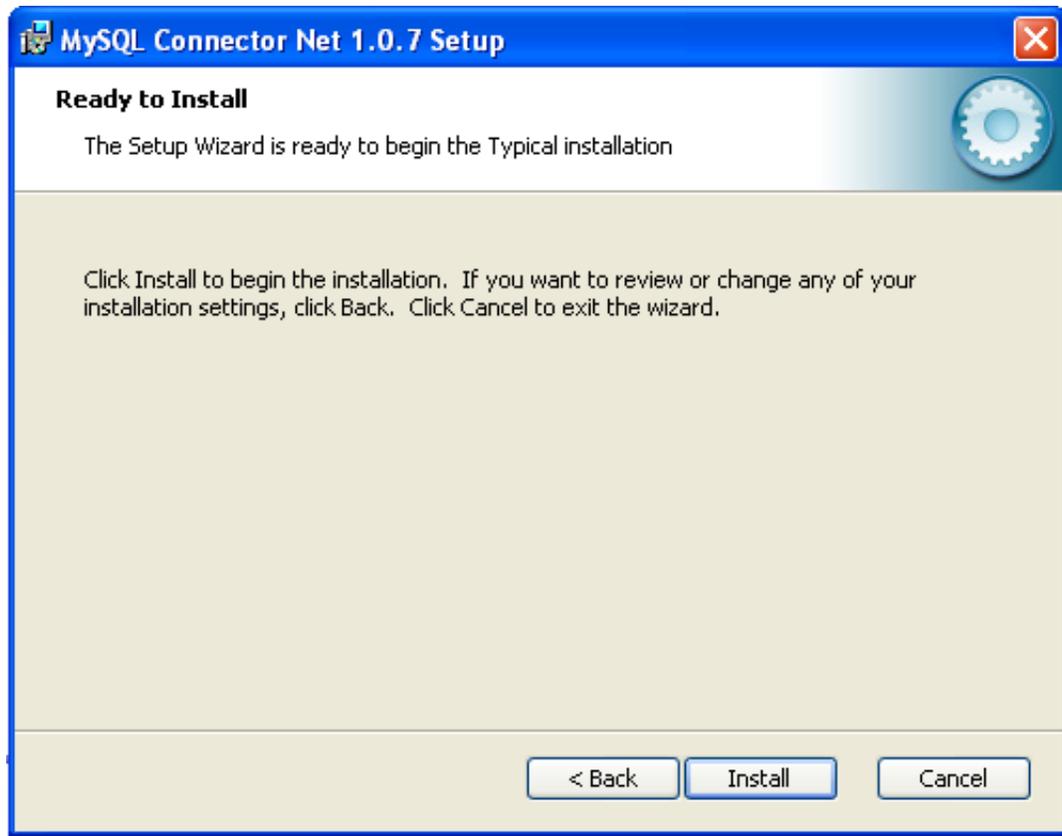

3. If you have chosen a custom installation, you can select the individual components that you want to install, including the core interface component, supporting documentation (a CHM file) samples and examples and the source code. Select the items, and their installation level, and then click [Next](#) to continue the installation.

4. For a custom installation you can also decide whether the Connector/NET component should be registered in the Global Assembly Cache - this will make the Connector/NET component available to all applications, not just those where you explicitly reference the Connector/NET component. You can also enable, or disable, the creation or appropriate items in the Start menu. Click [Next](#) when you have selected the required options.

5. You will be given a final opportunity to confirm the installation. Click [Install](#) to copy and install the files onto your machine.

6. Once the installation has been completed, click **Finish** to exit the installer.

Unless you choose otherwise, Connector/NET is installed in `C:\Program Files\MySQL\MySQL Connector Net X.X.X`, where `X.X.X` is replaced with the version of Connector/NET you are installing. New installations do not overwrite existing versions of Connector/NET.

Depending on your installation type, the installed components will include some or all of the following components:

- `bin` - Connector/NET MySQL libraries for different versions of the .NET environment.
- `docs` - contains a CHM of the Connector/NET documentation.
- `samples` - sample code and applications that use the Connector/NET component.
- `src` - the source code for the Connector/NET component.

You may also use the `/quiet` or `/q` command line option with the `msiexec` tool to install the Connector/NET package automatically (using the default options) with no notification to the user. Using this option you cannot select options and no prompts, messages or dialog boxes will be displayed.

```
C:\> msiexec /package connector-net.msi /quiet
```

To provide a progress bar to the user during automatic installation, but still without presenting the user with a dialog box of the ability to select options, use the `/passive` option.

25.2.2.1.2. Installing Connector/NET using the Zip package

If you are having problems running the installer, you can download a .zip file without an installer as an alternative. That file is called `mysql-connector-net-version-noinstall.zip`. Once downloaded, you can extract the files to a location of your choice.

The .zip file contains the following directories:

- `bin` - Connector/NET MySQL libraries for different versions of the .NET environment.
- `doc` - contains a CHM of the Connector/NET documentation.
- `Samples` - sample code and applications that use the Connector/NET component.
- `mysqlclient` - the source code for the Connector/NET component.
- `testsuite` - the test suite used to verify the operation of the Connector/NET component.

25.2.2.2. Installing Connector/NET on Unix with Mono

There is no installer available for installing the Connector/NET component on your Unix installation. However, the installation is very simple. Before installing, please ensure that you have a working Mono project installation.

Note that you should only install the Connector/NET component on Unix environments where you want to connect to a MySQL server through the Mono project. If you are deploying or developing on a different environment such as Java or Perl then you should use a more appropriate connectivity component. See the [Chapter 25, Connectors](#), or [Chapter 24, APIs and Libraries](#), for more information.

To install Connector/NET on Unix/Mono:

1. Download the `mysql-connector-net-version-noinstall.zip` and extract the contents.
2. Copy the `MySQL.Data.dll` file to your Mono project installation folder.
3. You must register the Connector/NET component in the Global Assembly Cache using the `gacutil` command:

```
shell> gacutil /i MySQL.Data.dll
```

Once installed, applications that are compiled with the Connector/NET component need no further changes. However, you must ensure that when you compile your applications you include the Connector/NET component using the `-r:MySQLData.dll` command line option.

25.2.2.3. Installing Connector/NET using the Source

Caution: You should read this section only if you are interested in helping us test our new code. If you just want to get Connector/NET up and running on your system, you should use a standard release distribution.

To be able to access the Connector/NET source tree, you must have Subversion installed. Subversion is freely available from <http://subversion.tigris.org/>.

The most recent development source tree is available from our public Subversion trees at <http://dev.mysql.com/tech-resources/sources.html>.

To checkout out the Connector/NET sources, change to the directory where you want the copy of the Connector/NET tree to be stored, then use the following command:

```
shell> svn co
http://svn.mysql.com/svnpublic/connector-net
```

A Visual Studio project is included in the source which you can use to build Connector/NET.

25.2.3. Connector/NET Examples

Connector/NET comprises several classes that are used to connect to the database, execute queries and statements, and manage query results.

The following are the major classes of Connector/NET:

- [MySqlCommand](#): Represents an SQL statement to execute against a MySQL database.
- [MySqlCommandBuilder](#): Automatically generates single-table commands used to reconcile changes made to a DataSet with the associated MySQL database.
- [MySqlConnection](#): Represents an open connection to a MySQL Server database.
- [MySqlDataAdapter](#): Represents a set of data commands and a database connection that are used to fill a dataset and update a MySQL database.
- [MySqlDataReader](#): Provides a means of reading a forward-only stream of rows from a MySQL database.
- [MySqlException](#): The exception that is thrown when MySQL returns an error.
- [MySqlHelper](#): Helper class that makes it easier to work with the provider.
- [MySqlTransaction](#): Represents an SQL transaction to be made in a MySQL database.

This section contains basic information and examples for each of the above classes. For a more detailed reference guide please see [Section 25.2.4, “Connector/NET Reference”](#).

25.2.3.1. MySqlCommand

Represents a SQL statement to execute against a MySQL database. This class cannot be inherited.

[MySqlCommand](#) features the following methods for executing commands at a MySQL database:

Item	Description
ExecuteReader	Executes commands that return rows.
ExecuteNonQuery	Executes commands such as SQL INSERT, DELETE, and UPDATE statements.
ExecuteScalar	Retrieves a single value (for example, an aggregate value) from a database.

You can reset the [CommandText](#) property and reuse the [MySqlCommand](#) object. However, you must

close the [MySqlDataReader](#) before you can execute a new or previous command.

If a [MySqlException](#) is generated by the method executing a [MySqlCommand](#), the [MySqlConnection](#) remains open. It is the responsibility of the programmer to close the connection.

Note. Prior versions of the provider used the '@' symbol to mark parameters in SQL. This is incompatible with MySQL user variables, so the provider now uses the '?' symbol to locate parameters in SQL. To support older code, you can set 'old syntax=yes' on your connection string. If you do this, please be aware that an exception will not be throw if you fail to define a parameter that you intended to use in your SQL.

Examples

The following example creates a [MySqlCommand](#) and a [MySqlConnection](#). The [MySqlConnection](#) is opened and set as the [Connection](#) for the [MySqlCommand](#). The example then calls [ExecuteNonQuery](#), and closes the connection. To accomplish this, the [ExecuteNonQuery](#) is passed a connection string and a query string that is a SQL INSERT statement.

Visual Basic example:

```
Public Sub InsertRow(myConnectionString As String)
    " If the connection string is null, use a default.
    If myConnectionString = "" Then
        myConnectionString = "Database=Test;Data Source=localhost;User Id=username;Password=pass"
    End If
    Dim myConnection As New MySqlConnection(myConnectionString)
    Dim myInsertQuery As String = "INSERT INTO Orders (id, customerId, amount) Values(1001, 23, 30.66)"
    Dim myCommand As New MySqlCommand(myInsertQuery)
    myCommand.Connection = myConnection
    myConnection.Open()
    myCommand.ExecuteNonQuery()
    myCommand.Connection.Close()
End Sub
```

C# example:

```
public void InsertRow(string myConnectionString)
{
    // If the connection string is null, use a default.
    if(myConnectionString == "")
    {
        myConnectionString = "Database=Test;Data Source=localhost;User Id=username;Password=pass";
    }
    MySqlConnection myConnection = new MySqlConnection(myConnectionString);
    string myInsertQuery = "INSERT INTO Orders (id, customerId, amount) Values(1001, 23, 30.66)";
    MySqlCommand myCommand = new MySqlCommand(myInsertQuery);
    myCommand.Connection = myConnection;
    myConnection.Open();
    myCommand.ExecuteNonQuery();
    myCommand.Connection.Close();
}
```

25.2.3.1.1. Class MySqlCommand Constructor Form 1

Overload methods for MySqlCommand

Initializes a new instance of the MySqlCommand class.

Examples

The following example creates a MySqlCommand and sets some of its properties.

Note. This example shows how to use one of the overloaded versions of the MySqlCommand constructor. For other examples that might be available, see the individual overload topics.

Visual Basic example:

```
Public Sub CreateMySQLCommand()
    Dim myConnection As New MySqlConnection _
        ("Persist Security Info=False;database=test;server=myServer")
    myConnection.Open()
    Dim myTrans As MySQLTransaction = myConnection.BeginTransaction()
    Dim mySelectQuery As String = "SELECT * FROM MyTable"
    Dim myCommand As New MySqlCommand(mySelectQuery, myConnection, myTrans)
    myCommand.CommandTimeout = 20
End Sub
```

C# example:

```
public void CreateMySQLCommand()
{
    MySqlConnection myConnection = new MySqlConnection("Persist Security Info=False;
        database=test;server=myServer");
    myConnection.Open();
    MySQLTransaction myTrans = myConnection.BeginTransaction();
    string mySelectQuery = "SELECT * FROM myTable";
    MySqlCommand myCommand = new MySqlCommand(mySelectQuery, myConnection, myTrans);
    myCommand.CommandTimeout = 20;
}
```

C++ example:

```
public:
void CreateMySQLCommand()
{
    MySqlConnection* myConnection = new MySqlConnection(S"Persist Security Info=False;
        database=test;server=myServer");
    myConnection->Open();
    MySQLTransaction* myTrans = myConnection->BeginTransaction();
    String* mySelectQuery = S"SELECT * FROM myTable";
    MySqlCommand* myCommand = new MySqlCommand(mySelectQuery, myConnection, myTrans);
    myCommand->CommandTimeout = 20;
};
```

Initializes a new instance of the `MySQLCommand` class.

The base constructor initializes all fields to their default values. The following table shows initial property values for an instance of `MySQLCommand`.

Properties	Initial Value
<code>CommandText</code>	empty string ("")
<code>CommandTimeout</code>	0
<code>CommandType</code>	<code>CommandType.Text</code>
<code>Connection</code>	Null

You can change the value for any of these properties through a separate call to the property.

Examples

The following example creates a `MySQLCommand` and sets some of its properties.

Visual Basic example:

```
Public Sub CreateMySQLCommand()
    Dim myCommand As New MySqlCommand()
    myCommand.CommandType = CommandType.Text
```

End Sub

C# example:

```
public void CreateMySQLCommand()
{
    MySqlCommand myCommand = new MySqlCommand();
    myCommand.CommandType = CommandType.Text;
}
```

25.2.3.1.2. Class MySqlCommand Constructor Form 2

Initializes a new instance of the [MySqlCommand](#) class with the text of the query.

Parameters: The text of the query.

When an instance of [MySqlCommand](#) is created, the following read/write properties are set to initial values.

Properties	Initial Value
CommandText	cmdText
CommandTimeout	0
CommandType	CommandType.Text
Connection	Null

You can change the value for any of these properties through a separate call to the property.

Examples

The following example creates a [MySqlCommand](#) and sets some of its properties.

Visual Basic example:

```
Public Sub CreateMySQLCommand()
    Dim sql as String = "SELECT * FROM mytable"
    Dim myCommand As New MySqlCommand(sql)
    myCommand.CommandType = CommandType.Text
End Sub
```

C# example:

```
public void CreateMySQLCommand()
{
    string sql = "SELECT * FROM mytable";
    MySqlCommand myCommand = new MySqlCommand(sql);
    myCommand.CommandType = CommandType.Text;
}
```

25.2.3.1.3. Class MySqlCommand Constructor Form 3

Initializes a new instance of the [MySqlCommand](#) class with the text of the query and a [MySQLConnection](#).

Parameters: The text of the query.

Parameters: A [MySQLConnection](#) that represents the connection to an instance of SQL Server.

When an instance of [MySqlCommand](#) is created, the following read/write properties are set to initial

values.

Properties	Initial Value
CommandText	cmdText
CommandTimeout	0
CommandType	CommandType.Text
Connection	connection

You can change the value for any of these properties through a separate call to the property.

Examples

The following example creates a [MySQLCommand](#) and sets some of its properties.

Visual Basic example:

```
Public Sub CreateMySQLCommand()
    Dim conn as new MySqlConnection("server=myServer")
    Dim sql as String = "SELECT * FROM mytable"
    Dim myCommand As New MySqlCommand(sql, conn)
    myCommand.CommandType = CommandType.Text
End Sub
```

C# example:

```
public void CreateMySQLCommand()
{
    MySqlConnection conn = new MySqlConnection("server=myserver")
    string sql = "SELECT * FROM mytable";
    MySqlCommand myCommand = new MySqlCommand(sql, conn);
    myCommand.CommandType = CommandType.Text;
}
```

25.2.3.1.4. Class MySqlCommand Constructor Form 4

Initializes a new instance of the [MySQLCommand](#) class with the text of the query, a [MySQLConnection](#), and the [MySQLTransaction](#).

Parameters: The text of the query.

Parameters: A [MySQLConnection](#) that represents the connection to an instance of SQL Server.

Parameters: The [MySQLTransaction](#) in which the [MySQLCommand](#) executes.

When an instance of [MySQLCommand](#) is created, the following read/write properties are set to initial values.

Properties	Initial Value
CommandText	cmdText
CommandTimeout	0
CommandType	CommandType.Text
Connection	connection

You can change the value for any of these properties through a separate call to the property.

Examples

The following example creates a [MySQLCommand](#) and sets some of its properties.

Visual Basic example:

```
Public Sub CreateMySQLCommand()
    Dim conn as new MySqlConnection("server=myServer")
    conn.Open();
    Dim txn as MySqlTransaction = conn.BeginTransaction()
    Dim sql as String = "SELECT * FROM mytable"
    Dim myCommand As New MySQLCommand(sql, conn, txn)
    myCommand.CommandType = CommandType.Text
End Sub
```

C# example:

```
public void CreateMySQLCommand()
{
    MySqlConnection conn = new MySqlConnection("server=myserver")
    conn.Open();
    MySqlTransaction txn = conn.BeginTransaction();
    string sql = "SELECT * FROM mytable";
    MySQLCommand myCommand = new MySQLCommand(sql, conn, txn);
    myCommand.CommandType = CommandType.Text;
}
```

25.2.3.1.5. ExecuteNonQuery

Executes a SQL statement against the connection and returns the number of rows affected.

Returns: Number of rows affected

You can use `ExecuteNonQuery` to perform any type of database operation, however any resultsets returned will not be available. Any output parameters used in calling a stored procedure will be populated with data and can be retrieved after execution is complete. For `UPDATE`, `INSERT`, and `DELETE` statements, the return value is the number of rows affected by the command. For all other types of statements, the return value is -1.

Examples

The following example creates a `MySQLCommand` and then executes it using `ExecuteNonQuery`. The example is passed a string that is a SQL statement (such as `UPDATE`, `INSERT`, or `DELETE`) and a string to use to connect to the data source.

Visual Basic example:

```
Public Sub CreateMySQLCommand(myExecuteQuery As String, myConnection As MySqlConnection)
    Dim myCommand As New MySQLCommand(myExecuteQuery, myConnection)
    myCommand.Connection.Open()
    myCommand.ExecuteNonQuery()
    myConnection.Close()
End Sub
```

C# example:

```
public void CreateMySQLCommand(string myExecuteQuery, MySqlConnection myConnection)
{
    MySQLCommand myCommand = new MySQLCommand(myExecuteQuery, myConnection);
    myCommand.Connection.Open();
    myCommand.ExecuteNonQuery();
    myConnection.Close();
}
```

25.2.3.1.6. ExecuteReader1

Sends the `CommandText` to the `MySqlConnection` `Connection`, and builds a `MySqlDataReader` using one of the `CommandBehavior` values.

Parameters: One of the `CommandBehavior` values.

When the `CommandType` property is set to `StoredProcedure`, the `CommandText` property should be set to the name of the stored procedure. The command executes this stored procedure when you call `ExecuteReader`.

The `MySqlDataReader` supports a special mode that enables large binary values to be read efficiently. For more information, see the `SequentialAccess` setting for `CommandBehavior`.

While the `MySqlDataReader` is in use, the associated `MySqlConnection` is busy serving the `MySqlDataReader`. While in this state, no other operations can be performed on the `MySqlConnection` other than closing it. This is the case until the `MySqlDataReader.Close` method of the `MySqlDataReader` is called. If the `MySqlDataReader` is created with `CommandBehavior` set to `CloseConnection`, closing the `MySqlDataReader` closes the connection automatically.

Note. When calling `ExecuteReader` with the `SingleRow` behavior, you should be aware that using a `limit` clause in your SQL will cause all rows (up to the limit given) to be retrieved by the client. The `MySqlDataReader.Read` method will still return `false` after the first row but pulling all rows of data into the client will have a performance impact. If the `limit` clause is not necessary, it should be avoided.

Returns: A `MySqlDataReader` object.

25.2.3.1.7. ExecuteReader

Sends the `CommandText` to the `MySqlConnection` `Connection` and builds a `MySqlDataReader`.

Returns: A `MySqlDataReader` object.

When the `CommandType` property is set to `StoredProcedure`, the `CommandText` property should be set to the name of the stored procedure. The command executes this stored procedure when you call `ExecuteReader`.

While the `MySqlDataReader` is in use, the associated `MySqlConnection` is busy serving the `MySqlDataReader`. While in this state, no other operations can be performed on the `MySqlConnection` other than closing it. This is the case until the `MySqlDataReader.Close` method of the `MySqlDataReader` is called.

Examples

The following example creates a `MySqlCommand`, then executes it by passing a string that is a SQL `SELECT` statement, and a string to use to connect to the data source.

Visual Basic example:

```
Public Sub CreateMySqlDataReader(mySelectQuery As String, myConnection As MySqlConnection)
    Dim myCommand As New MySqlCommand(mySelectQuery, myConnection)
    myConnection.Open()
    Dim myReader As MySqlDataReader
    myReader = myCommand.ExecuteReader()
    Try
        While myReader.Read()
            Console.WriteLine(myReader.GetString(0))
        End While
    Finally
        myReader.Close()
        myConnection.Close()
    End Try
End Sub
```

```
End Try
End Sub
```

C# example:

```
public void CreateMySqlDataReader(string mySelectQuery, MySqlConnection myConnection)
{
    MySqlCommand myCommand = new MySqlCommand(mySelectQuery, myConnection);
    myConnection.Open();
    MySqlDataReader myReader;
    myReader = myCommand.ExecuteReader();
    try
    {
        while(myReader.Read())
        {
            Console.WriteLine(myReader.GetString(0));
        }
    }
    finally
    {
        myReader.Close();
        myConnection.Close();
    }
}
```

25.2.3.1.8. Prepare

Creates a prepared version of the command on an instance of MySQL Server.

Prepared statements are only supported on MySQL version 4.1 and higher. Calling prepare while connected to earlier versions of MySQL will succeed but will execute the statement in the same way as unprepared.

Examples

The following example demonstrates the use of the [Prepare](#) method.

Visual Basic example:

```
public sub PrepareExample()
    Dim cmd as New MySqlCommand("INSERT INTO mytable VALUES (?val)", myConnection)
    cmd.Parameters.Add( "?val", 10 )
    cmd.Prepare()
    cmd.ExecuteNonQuery()

    cmd.Parameters(0).Value = 20
    cmd.ExecuteNonQuery()
end sub
```

C# example:

```
private void PrepareExample()
{
    MySqlCommand cmd = new MySqlCommand("INSERT INTO mytable VALUES (?val)", myConnection);
    cmd.Parameters.Add( "?val", 10 );
    cmd.Prepare();
    cmd.ExecuteNonQuery();

    cmd.Parameters[0].Value = 20;
    cmd.ExecuteNonQuery();
}
```

25.2.3.1.9. ExecuteScalar

Executes the query, and returns the first column of the first row in the result set returned by the query. Extra columns or rows are ignored.

Returns: The first column of the first row in the result set, or a null reference if the result set is empty

Use the [ExecuteScalar](#) method to retrieve a single value (for example, an aggregate value) from a database. This requires less code than using the [ExecuteReader](#) method, and then performing the operations necessary to generate the single value using the data returned by a [MySqlDataReader](#)

A typical [ExecuteScalar](#) query can be formatted as in the following C# example:

C# example:

```
cmd.CommandText = "select count(*) from region";
Int32 count = (int32) cmd.ExecuteScalar();
```

Examples

The following example creates a [MySqlCommand](#) and then executes it using [ExecuteScalar](#). The example is passed a string that is a SQL statement that returns an aggregate result, and a string to use to connect to the data source.

Visual Basic example:

```
Public Sub CreateMySqlCommand(myScalarQuery As String, myConnection As MySqlConnection)
    Dim myCommand As New MySqlCommand(myScalarQuery, myConnection)
    myCommand.Connection.Open()
    myCommand.ExecuteScalar()
    myConnection.Close()
End Sub
```

C# example:

```
public void CreateMySqlCommand(string myScalarQuery, MySqlConnection myConnection)
{
    MySqlCommand myCommand = new MySqlCommand(myScalarQuery, myConnection);
    myCommand.Connection.Open();
    myCommand.ExecuteScalar();
    myConnection.Close();
}
```

C++ example:

```
public:
    void CreateMySqlCommand(String* myScalarQuery, MySqlConnection* myConnection)
    {
        MySqlCommand* myCommand = new MySqlCommand(myScalarQuery, myConnection);
        myCommand->Connection->Open();
        myCommand->ExecuteScalar();
        myConnection->Close();
    }
```

25.2.3.1.10. CommandText

Gets or sets the SQL statement to execute at the data source.

Value: The SQL statement or stored procedure to execute. The default is an empty string.

When the [CommandType](#) property is set to [StoredProcedure](#), the [CommandText](#) property should be set to the name of the stored procedure. The user may be required to use escape character syntax if the stored procedure name contains any special characters. The command executes this stored pro-

cedure when you call one of the Execute methods.

Examples

The following example creates a [MySQLCommand](#) and sets some of its properties.

Visual Basic example:

```
Public Sub CreateMySQLCommand()  
    Dim myCommand As New MySQLCommand()  
    myCommand.CommandText = "SELECT * FROM Mytable ORDER BY id"  
    myCommand.CommandType = CommandType.Text  
End Sub
```

C# example:

```
public void CreateMySQLCommand()  
{  
    MySqlCommand myCommand = new MySqlCommand();  
    myCommand.CommandText = "SELECT * FROM mytable ORDER BY id";  
    myCommand.CommandType = CommandType.Text;  
}
```

25.2.3.1.11. CommandTimeout

Gets or sets the wait time before terminating the attempt to execute a command and generating an error.

Value: The time (in seconds) to wait for the command to execute. The default is 0 seconds.

MySQL currently does not support any method of canceling a pending or executing operation. All commands issued against a MySQL server will execute until completion or exception occurs.

25.2.3.1.12. CommandType

Gets or sets a value indicating how the [CommandText](#) property is to be interpreted.

Value: One of the [System.Data.CommandType](#) values. The default is [Text](#).

When you set the [CommandType](#) property to [StoredProcedure](#), you should set the [CommandText](#) property to the name of the stored procedure. The command executes this stored procedure when you call one of the Execute methods.

Examples

The following example creates a [MySQLCommand](#) and sets some of its properties.

Visual Basic example:

```
Public Sub CreateMySQLCommand()  
    Dim myCommand As New MySQLCommand()  
    myCommand.CommandType = CommandType.Text  
End Sub
```

C# example:

```
public void CreateMySQLCommand()  
{  
    MySqlCommand myCommand = new MySqlCommand();  
    myCommand.CommandType = CommandType.Text;  
}
```

25.2.3.1.13. Connection

Gets or sets the [MySQLConnection](#) used by this instance of the [MySQLCommand](#).

Value: The connection to a data source. The default value is a null reference ([Nothing](#) in Visual Basic).

If you set [Connection](#) while a transaction is in progress and the [Transaction](#) property is not null, an [InvalidOperationException](#) is generated. If the [Transaction](#) property is not null and the transaction has already been committed or rolled back, [Transaction](#) is set to null.

Examples

The following example creates a [MySQLCommand](#) and sets some of its properties.

Visual Basic example:

```
Public Sub CreateMySQLCommand()
    Dim mySelectQuery As String = "SELECT * FROM mytable ORDER BY id"
    Dim myConnectionString As String = "Persist Security Info=False;database=test;server=myServer"
    Dim myCommand As New MySQLCommand(mySelectQuery)
    myCommand.Connection = New MySQLConnection(myConnectionString)
    myCommand.CommandType = CommandType.Text
End Sub
```

C# example:

```
public void CreateMySQLCommand()
{
    string mySelectQuery = "SELECT * FROM mytable ORDER BY id";
    string myConnectionString = "Persist Security Info=False;database=test;server=myServer";
    MySQLCommand myCommand = new MySQLCommand(mySelectQuery);
    myCommand.Connection = new MySQLConnection(myConnectionString);
    myCommand.CommandType = CommandType.Text;
}
```

25.2.3.1.14. IsPrepared

Returns true if the statement is prepared.

25.2.3.1.15. Parameters

Get the [MySQLParameterCollection](#)

Value: The parameters of the SQL statement or stored procedure. The default is an empty collection.

Connector/Net does not support unnamed parameters. Every parameter added to the collection must have an associated name.

Examples

The following example creates a [MySQLCommand](#) and displays its parameters. To accomplish this, the method is passed a [MySQLConnection](#), a query string that is a SQL [SELECT](#) statement, and an array of [MySQLParameter](#) objects.

Visual Basic example:

```
Public Sub CreateMySQLCommand(myConnection As MySQLConnection, _
mySelectQuery As String, myParamArray() As MySQLParameter)
    Dim myCommand As New MySQLCommand(mySelectQuery, myConnection)
    myCommand.CommandText = "SELECT id, name FROM mytable WHERE age=?age"
    myCommand.UpdatedRowSource = UpdateRowSource.Both
    myCommand.Parameters.Add(myParamArray)
    Dim j As Integer
    For j = 0 To myCommand.Parameters.Count - 1
```

```

        myCommand.Parameters.Add(myParamArray(j))
    Next j
    Dim myMessage As String = ""
    Dim i As Integer
    For i = 0 To myCommand.Parameters.Count - 1
        myMessage += myCommand.Parameters(i).ToString() & ControlChars.Cr
    Next i
    Console.WriteLine(myMessage)
End Sub

```

C# example:

```

public void CreateMySQLCommand(MySqlConnection myConnection, string mySelectQuery,
    MySqlParameter[] myParamArray)
{
    MySqlCommand myCommand = new MySqlCommand(mySelectQuery, myConnection);
    myCommand.CommandText = "SELECT id, name FROM mytable WHERE age=?age";
    myCommand.Parameters.Add(myParamArray);
    for (int j=0; j<myParamArray.Length; j++)
    {
        myCommand.Parameters.Add(myParamArray[j]) ;
    }
    string myMessage = "";
    for (int i = 0; i < myCommand.Parameters.Count; i++)
    {
        myMessage += myCommand.Parameters[i].ToString() + "\n";
    }
    MessageBox.Show(myMessage);
}

```

25.2.3.1.16. Transaction

Gets or sets the [MySQLTransaction](#) within which the [MySQLCommand](#) executes.

Value: The [MySQLTransaction](#). The default value is a null reference ([Nothing](#) in Visual Basic).

You cannot set the [Transaction](#) property if it is already set to a specific value, and the command is in the process of executing. If you set the transaction property to a [MySQLTransaction](#) object that is not connected to the same [MySQLConnection](#) as the [MySQLCommand](#) object, an exception will be thrown the next time you attempt to execute a statement.

25.2.3.1.17. UpdatedRowSource

Gets or sets how command results are applied to the [DataRow](#) when used by the [System.Data.Common.DbDataAdapter.Update](#) method of the [System.Data.Common.DbDataAdapter](#).

Value: One of the [UpdateRowSource](#) values.

The default [System.Data.UpdateRowSource](#) value is [Both](#) unless the command is automatically generated (as in the case of the [MySQLCommandBuilder](#)), in which case the default is [None](#).

25.2.3.2. MySqlCommandBuilder

Automatically generates single-table commands used to reconcile changes made to a [DataSet](#) with the associated [MySQL](#) database. This class cannot be inherited.

The [MySQLDataAdapter](#) does not automatically generate the SQL statements required to reconcile changes made to a [System.Data.DataSet](#) with the associated instance of [MySQL](#). However, you can create a [MySQLCommandBuilder](#) object to automatically generate SQL statements for single-table updates if you set the [MySQLDataAdapter.SelectCommand](#) property of the [MySQLDataAdapter](#). Then, any additional SQL statements that you do not set are generated by the [MySQLCommandBuilder](#).

The `MySqlCommandBuilder` registers itself as a listener for `MySqlDataAdapter.OnRowUpdating` events whenever you set the `DataAdapter` property. You can only associate one `MySqlDataAdapter` or `MySqlCommandBuilder` object with each other at one time.

To generate INSERT, UPDATE, or DELETE statements, the `MySqlCommandBuilder` uses the `SelectCommand` property to retrieve a required set of metadata automatically. If you change the `SelectCommand` after the metadata has been retrieved (for example, after the first update), you should call the `RefreshSchema` method to update the metadata.

The `SelectCommand` must also return at least one primary key or unique column. If none are present, an `InvalidOperationException` exception is generated, and the commands are not generated.

The `MySqlCommandBuilder` also uses the `MySqlCommand.Connection`, `MySqlCommand.CommandTimeout`, and `MySqlCommand.Transaction` properties referenced by the `SelectCommand`. The user should call `RefreshSchema` if any of these properties are modified, or if the `SelectCommand` itself is replaced. Otherwise the `MySqlDataAdapter.InsertCommand`, `MySqlDataAdapter.UpdateCommand`, and `MySqlDataAdapter.DeleteCommand` properties retain their previous values.

If you call `Dispose`, the `MySqlCommandBuilder` is disassociated from the `MySqlDataAdapter`, and the generated commands are no longer used.

Note. Caution must be used when using `MySqlCommandBuilder` on MySQL 4.0 systems. With MySQL 4.0, database/schema information is not provided to the connector for a query. This means that a query that pulls columns from two identically named tables in two or more different databases will not cause an exception to be thrown but will not work correctly. Even more dangerous is the situation where your select statement references database X but is executed in database Y and both databases have tables with similar layouts. This situation can cause unwanted changes or deletes. This note does not apply to MySQL versions 4.1 and later.

Examples

The following example uses the `MySqlCommand`, along `MySqlDataAdapter` and `MySqlConnection`, to select rows from a data source. The example is passed an initialized `System.Data.DataSet`, a connection string, a query string that is a SQL `SELECT` statement, and a string that is the name of the database table. The example then creates a `MySqlCommandBuilder`.

Visual Basic example:

```
Public Shared Function SelectRows(myConnection As String, mySelectQuery As String, myTableName As String)
    Dim myConn As New MySqlConnection(myConnection)
    Dim myDataAdapter As New MySqlDataAdapter()
    myDataAdapter.SelectCommand = New MySqlCommand(mySelectQuery, myConn)
    Dim cb As SqlCommandBuilder = New MySqlCommandBuilder(myDataAdapter)
    myConn.Open()
    Dim ds As DataSet = New DataSet
    myDataAdapter.Fill(ds, myTableName)
    ' Code to modify data in DataSet here
    ' Without the MySqlCommandBuilder this line would fail.
    myDataAdapter.Update(ds, myTableName)
    myConn.Close()
End Function 'SelectRows
```

C# example:

```
public static DataSet SelectRows(string myConnection, string mySelectQuery, string myTableName)
{
    MySqlConnection myConn = new MySqlConnection(myConnection);
    MySqlDataAdapter myDataAdapter = new MySqlDataAdapter();
    myDataAdapter.SelectCommand = new MySqlCommand(mySelectQuery, myConn);
```

```
MySQLCommandBuilder cb = new MySQLCommandBuilder(myDataAdapter);
myConn.Open();
DataSet ds = new DataSet();
myDataAdapter.Fill(ds, myTableName);
//code to modify data in DataSet here
//Without the MySQLCommandBuilder this line would fail
myDataAdapter.Update(ds, myTableName);
myConn.Close();
return ds;
}
```

25.2.3.2.1. Class MySQLCommandBuilder Constructor

Initializes a new instance of the [MySQLCommandBuilder](#) class.

25.2.3.2.2. Class MySQLCommandBuilder Constructor Form 1

Initializes a new instance of the [MySQLCommandBuilder](#) class and sets the last one wins property.

Parameters: False to generate change protection code. True otherwise.

The [lastOneWins](#) parameter indicates whether SQL code should be included with the generated DELETE and UPDATE commands that checks the underlying data for changes. If [lastOneWins](#) is true then this code is not included and data records could be overwritten in a multi-user or multi-threaded environments. Setting [lastOneWins](#) to false will include this check which will cause a concurrency exception to be thrown if the underlying data record has changed without our knowledge.

25.2.3.2.3. Class MySQLCommandBuilder Constructor Form 2

Initializes a new instance of the [MySQLCommandBuilder](#) class with the associated [MySQLDataAdapter](#) object.

Parameters: The [MySQLDataAdapter](#) to use.

The [MySQLCommandBuilder](#) registers itself as a listener for [MySQLDataAdapter.RowUpdating](#) events that are generated by the [MySQLDataAdapter](#) specified in this property.

When you create a new instance [MySQLCommandBuilder](#), any existing [MySQLCommandBuilder](#) associated with this [MySQLDataAdapter](#) is released.

25.2.3.2.4. Class MySQLCommandBuilder Constructor Form 3

Initializes a new instance of the [MySQLCommandBuilder](#) class with the associated [MySQLDataAdapter](#) object.

Parameters: The [MySQLDataAdapter](#) to use.

Parameters: False to generate change protection code. True otherwise.

The [MySQLCommandBuilder](#) registers itself as a listener for [MySQLDataAdapter.RowUpdating](#) events that are generated by the [MySQLDataAdapter](#) specified in this property.

When you create a new instance [MySQLCommandBuilder](#), any existing [MySQLCommandBuilder](#) associated with this [MySQLDataAdapter](#) is released.

The [lastOneWins](#) parameter indicates whether SQL code should be included with the generated DELETE and UPDATE commands that checks the underlying data for changes. If [lastOneWins](#) is true then this code is not included and data records could be overwritten in a multi-user or multi-threaded en-

vironments. Setting `lastOneWins` to false will include this check which will cause a concurrency exception to be thrown if the underlying data record has changed without our knowledge.

25.2.3.2.5. DataAdapter

Gets or sets a `MySqlDataAdapter` object for which SQL statements are automatically generated.

Value: A `MySqlDataAdapter` object.

The `MySqlCommandBuilder` registers itself as a listener for `MySqlDataAdapter.RowUpdating` events that are generated by the `MySqlDataAdapter` specified in this property.

When you create a new instance `MySqlCommandBuilder`, any existing `MySqlCommandBuilder` associated with this `MySqlDataAdapter` is released.

25.2.3.2.6. QuotePrefix

Gets or sets the beginning character or characters to use when specifying MySQL database objects (for example, tables or columns) whose names contain characters such as spaces or reserved tokens.

Value: The beginning character or characters to use. The default value is ```.

Database objects in MySQL can contain special characters such as spaces that would make normal SQL strings impossible to correctly parse. Use of the `QuotePrefix` and the `QuoteSuffix` properties allows the `MySqlCommandBuilder` to build SQL commands that handle this situation.

25.2.3.2.7. QuoteSuffix

Gets or sets the beginning character or characters to use when specifying MySQL database objects (for example, tables or columns) whose names contain characters such as spaces or reserved tokens.

Value: The beginning character or characters to use. The default value is ```.

Database objects in MySQL can contain special characters such as spaces that would make normal SQL strings impossible to correctly parse. Use of the `QuotePrefix` and the `QuoteSuffix` properties allows the `MySqlCommandBuilder` to build SQL commands that handle this situation.

25.2.3.2.8. DeriveParameters

25.2.3.2.9. GetDeleteCommand

Gets the automatically generated `MySqlCommand` object required to perform deletions on the database.

Returns: The `MySqlCommand` object generated to handle delete operations.

An application can use the `GetDeleteCommand` method for informational or troubleshooting purposes because it returns the `MySqlCommand` object to be executed.

You can also use `GetDeleteCommand` as the basis of a modified command. For example, you might call `GetDeleteCommand` and modify the `MySqlCommand.CommandTimeout` value, and then explicitly set that on the `MySqlDataAdapter`.

After the SQL statement is first generated, the application must explicitly call `RefreshSchema` if it changes the statement in any way. Otherwise, the `GetDeleteCommand` will be still be using information from the previous statement, which might not be correct. The SQL statements are first generated either when the application calls `System.Data.Common.DataAdapter.Update` or `GetDe-`

[leteCommand](#).

25.2.3.2.10. GetInsertCommand

Gets the automatically generated [MySQLCommand](#) object required to perform insertions on the database.

Returns: The [MySQLCommand](#) object generated to handle insert operations.

An application can use the [GetInsertCommand](#) method for informational or troubleshooting purposes because it returns the [MySQLCommand](#) object to be executed.

You can also use the [GetInsertCommand](#) as the basis of a modified command. For example, you might call [GetInsertCommand](#) and modify the [MySQLCommand.CommandTimeout](#) value, and then explicitly set that on the [MySQLDataAdapter](#).

After the SQL statement is first generated, the application must explicitly call [RefreshSchema](#) if it changes the statement in any way. Otherwise, the [GetInsertCommand](#) will be still be using information from the previous statement, which might not be correct. The SQL statements are first generated either when the application calls [System.Data.Common.DataAdapter.Update](#) or [GetInsertCommand](#).

25.2.3.2.11. GetUpdateCommand

Gets the automatically generated [MySQLCommand](#) object required to perform updates on the database.

Returns: The [MySQLCommand](#) object generated to handle update operations.

An application can use the [GetUpdateCommand](#) method for informational or troubleshooting purposes because it returns the [MySQLCommand](#) object to be executed.

You can also use [GetUpdateCommand](#) as the basis of a modified command. For example, you might call [GetUpdateCommand](#) and modify the [MySQLCommand.CommandTimeout](#) value, and then explicitly set that on the [MySQLDataAdapter](#).

After the SQL statement is first generated, the application must explicitly call [RefreshSchema](#) if it changes the statement in any way. Otherwise, the [GetUpdateCommand](#) will be still be using information from the previous statement, which might not be correct. The SQL statements are first generated either when the application calls [System.Data.Common.DataAdapter.Update](#) or [GetUpdateCommand](#).

25.2.3.2.12. RefreshSchema

Refreshes the database schema information used to generate INSERT, UPDATE, or DELETE statements.

An application should call [RefreshSchema](#) whenever the [SELECT](#) statement associated with the [MySQLCommandBuilder](#) changes.

An application should call [RefreshSchema](#) whenever the [MySQLDataAdapter.SelectCommand](#) value of the [MySQLDataAdapter](#) changes.

25.2.3.3. MySqlConnection

Represents an open connection to a MySQL Server database. This class cannot be inherited.

A [MySqlConnection](#) object represents a session to a MySQL Server data source. When you create an instance of [MySqlConnection](#), all properties are set to their initial values. For a list of these values, see the [MySqlConnection](#) constructor.

If the `MySqlConnection` goes out of scope, it is not closed. Therefore, you must explicitly close the connection by calling `MySqlConnection.Close` or `MySqlConnection.Dispose`.

Examples

The following example creates a `MySqlCommand` and a `MySqlConnection`. The `MySqlConnection` is opened and set as the `MySqlCommand.Connection` for the `MySqlCommand`. The example then calls `MySqlCommand.ExecuteNonQuery`, and closes the connection. To accomplish this, the `ExecuteNonQuery` is passed a connection string and a query string that is a SQL INSERT statement.

Visual Basic example:

```
Public Sub InsertRow(myConnectionString As String)
    ' If the connection string is null, use a default.
    If myConnectionString = "" Then
        myConnectionString = "Database=Test;Data Source=localhost;User Id=username;Password=pass"
    End If
    Dim myConnection As New MySqlConnection(myConnectionString)
    Dim myInsertQuery As String = "INSERT INTO Orders (id, customerId, amount) Values(1001, 23, 30.66)"
    Dim myCommand As New MySqlCommand(myInsertQuery)
    myCommand.Connection = myConnection
    myConnection.Open()
    myCommand.ExecuteNonQuery()
    myCommand.Connection.Close()
End Sub
```

C# example:

```
public void InsertRow(string myConnectionString)
{
    // If the connection string is null, use a default.
    if(myConnectionString == "")
    {
        myConnectionString = "Database=Test;Data Source=localhost;User Id=username;Password=pass";
    }
    MySqlConnection myConnection = new MySqlConnection(myConnectionString);
    string myInsertQuery = "INSERT INTO Orders (id, customerId, amount) Values(1001, 23, 30.66)";
    MySqlCommand myCommand = new MySqlCommand(myInsertQuery);
    myCommand.Connection = myConnection;
    myConnection.Open();
    myCommand.ExecuteNonQuery();
    myCommand.Connection.Close();
}
```

25.2.3.3.1. Class MySqlConnection Constructor (Default)

Initializes a new instance of the `MySqlConnection` class.

When a new instance of `MySqlConnection` is created, the read/write properties are set to the following initial values unless they are specifically set using their associated keywords in the `ConnectionString` property.

Properties	Initial Value
<code>ConnectionString</code>	empty string ("")
<code>ConnectionTimeout</code>	15
<code>Database</code>	empty string ("")
<code>DataSource</code>	empty string ("")
<code>ServerVersion</code>	empty string ("")

You can change the value for these properties only by using the [ConnectionString](#) property.

Examples

Overload methods for MySqlConnection

Initializes a new instance of the [MySqlConnection](#) class.

25.2.3.3.2. Class MySqlConnection Constructor Form 1

Initializes a new instance of the [MySqlConnection](#) class when given a string containing the connection string.

When a new instance of [MySqlConnection](#) is created, the read/write properties are set to the following initial values unless they are specifically set using their associated keywords in the [ConnectionString](#) property.

Properties	Initial Value
ConnectionString	empty string ("")
ConnectionTimeout	15
Database	empty string ("")
DataSource	empty string ("")
ServerVersion	empty string ("")

You can change the value for these properties only by using the [ConnectionString](#) property.

Examples

Parameters: The connection properties used to open the MySQL database.

25.2.3.3.3. Open

Opens a database connection with the property settings specified by the [ConnectionString](#).

Exception: Cannot open a connection without specifying a data source or server.

Exception: A connection-level error occurred while opening the connection.

The [MySqlConnection](#) draws an open connection from the connection pool if one is available. Otherwise, it establishes a new connection to an instance of MySQL.

Examples

The following example creates a [MySqlConnection](#), opens it, displays some of its properties, then closes the connection.

Visual Basic example:

```
Public Sub CreateMySqlConnection(myConnString As String)
    Dim myConnection As New MySqlConnection(myConnString)
    myConnection.Open()
    MessageBox.Show("ServerVersion: " + myConnection.ServerVersion _
        + ControlChars.Cr + "State: " + myConnection.State.ToString())
    myConnection.Close()
End Sub
```

C# example:

```
public void CreateMySQLConnection(string myConnString)
{
    MySqlConnection myConnection = new MySqlConnection(myConnString);
    myConnection.Open();
    MessageBox.Show("ServerVersion: " + myConnection.ServerVersion +
        "\nState: " + myConnection.State.ToString());
    myConnection.Close();
}
```

25.2.3.3.4. Database

Gets the name of the current database or the database to be used after a connection is opened.

Returns: The name of the current database or the name of the database to be used after a connection is opened. The default value is an empty string.

The [Database](#) property does not update dynamically. If you change the current database using a SQL statement, then this property may reflect the wrong value. If you change the current database using the [ChangeDatabase](#) method, this property is updated to reflect the new database.

Examples

The following example creates a [MySQLConnection](#) and displays some of its read-only properties.

Visual Basic example:

```
Public Sub CreateMySQLConnection()
    Dim myConnString As String = _
        "Persist Security Info=False;database=test;server=localhost;user id=joeuser;pwd=pass"
    Dim myConnection As New MySqlConnection( myConnString )
    myConnection.Open()
    MessageBox.Show( "Server Version: " + myConnection.ServerVersion _
        + ControlChars.NewLine + "Database: " + myConnection.Database )
    myConnection.ChangeDatabase( "test2" )
    MessageBox.Show( "ServerVersion: " + myConnection.ServerVersion _
        + ControlChars.NewLine + "Database: " + myConnection.Database )
    myConnection.Close()
End Sub
```

C# example:

```
public void CreateMySQLConnection()
{
    string myConnString =
        "Persist Security Info=False;database=test;server=localhost;user id=joeuser;pwd=pass";
    MySqlConnection myConnection = new MySqlConnection( myConnString );
    myConnection.Open();
    MessageBox.Show( "Server Version: " + myConnection.ServerVersion
        + "\nDatabase: " + myConnection.Database );
    myConnection.ChangeDatabase( "test2" );
    MessageBox.Show( "ServerVersion: " + myConnection.ServerVersion
        + "\nDatabase: " + myConnection.Database );
    myConnection.Close();
}
```

25.2.3.3.5. State

Gets the current state of the connection.

Returns: A bitwise combination of the [System.Data.ConnectionState](#) values. The default is [Closed](#).

The allowed state changes are:

- From [Closed](#) to [Open](#), using the [Open](#) method of the connection object.
- From [Open](#) to [Closed](#), using either the [Close](#) method or the [Dispose](#) method of the connection object.

Examples

The following example creates a [MySQLConnection](#), opens it, displays some of its properties, then closes the connection.

Visual Basic example:

```
Public Sub CreateMySQLConnection(myConnString As String)
    Dim myConnection As New MySqlConnection(myConnString)
    myConnection.Open()
    MessageBox.Show("ServerVersion: " + myConnection.ServerVersion _
        + ControlChars.Cr + "State: " + myConnection.State.ToString())
    myConnection.Close()
End Sub
```

C# example:

```
public void CreateMySQLConnection(string myConnString)
{
    MySqlConnection myConnection = new MySqlConnection(myConnString);
    myConnection.Open();
    MessageBox.Show("ServerVersion: " + myConnection.ServerVersion +
        "\nState: " + myConnection.State.ToString());
    myConnection.Close();
}
```

25.2.3.3.6. ServerVersion

Gets a string containing the version of the MySQL server to which the client is connected.

Returns: The version of the instance of MySQL.

Exception: The connection is closed.

Examples

The following example creates a [MySQLConnection](#), opens it, displays some of its properties, then closes the connection.

Visual Basic example:

```
Public Sub CreateMySQLConnection(myConnString As String)
    Dim myConnection As New MySqlConnection(myConnString)
    myConnection.Open()
    MessageBox.Show("ServerVersion: " + myConnection.ServerVersion _
        + ControlChars.Cr + "State: " + myConnection.State.ToString())
    myConnection.Close()
End Sub
```

C# example:

```
public void CreateMySQLConnection(string myConnString)
{
```

```
MySqlConnection myConnection = new MySqlConnection(myConnString);
myConnection.Open();
MessageBox.Show("ServerVersion: " + myConnection.ServerVersion +
"\nState: " + myConnection.State.ToString());
myConnection.Close();
}
```

25.2.3.3.7. Close

Closes the connection to the database. This is the preferred method of closing any open connection.

The `Close` method rolls back any pending transactions. It then releases the connection to the connection pool, or closes the connection if connection pooling is disabled.

An application can call `Close` more than one time. No exception is generated.

Examples

The following example creates a `MySqlConnection`, opens it, displays some of its properties, then closes the connection.

Visual Basic example:

```
Public Sub CreateMySqlConnection(myConnString As String)
    Dim myConnection As New MySqlConnection(myConnString)
    myConnection.Open()
    MessageBox.Show("ServerVersion: " + myConnection.ServerVersion _
+ ControlChars.Cr + "State: " + myConnection.State.ToString())
    myConnection.Close()
End Sub
```

C# example:

```
public void CreateMySqlConnection(string myConnString)
{
    MySqlConnection myConnection = new MySqlConnection(myConnString);
    myConnection.Open();
    MessageBox.Show("ServerVersion: " + myConnection.ServerVersion +
"\nState: " + myConnection.State.ToString());
    myConnection.Close();
}
```

25.2.3.3.8. CreateCommand

Creates and returns a `MySqlCommand` object associated with the `MySqlConnection`.

Returns: A `MySqlCommand` object.

25.2.3.3.9. BeginTransaction

Begins a database transaction.

Returns: An object representing the new transaction.

Exception: Parallel transactions are not supported.

This command is equivalent to the MySQL `BEGIN TRANSACTION` command.

You must explicitly commit or roll back the transaction using the `MySqlTransaction.Commit` or `MySqlTransaction.Rollback` method.

Note. If you do not specify an isolation level, the default isolation level is used. To specify an isolation level with the [BeginTransaction](#) method, use the overload that takes the `iso` parameter.

Examples

The following example creates a [MySQLConnection](#) and a [MySQLTransaction](#). It also demonstrates how to use the [BeginTransaction](#), a [MySQLTransaction.Commit](#), and [MySQLTransaction.Rollback](#) methods.

Visual Basic example:

```
Public Sub RunTransaction(myConnString As String)
    Dim myConnection As New MySqlConnection(myConnString)
    myConnection.Open()

    Dim myCommand As MySqlCommand = myConnection.CreateCommand()
    Dim myTrans As MySQLTransaction

    ' Start a local transaction
    myTrans = myConnection.BeginTransaction()
    ' Must assign both transaction object and connection
    ' to Command object for a pending local transaction
    myCommand.Connection = myConnection
    myCommand.Transaction = myTrans

    Try
        myCommand.CommandText = "Insert into Test (id, desc) VALUES (100, 'Description')"
        myCommand.ExecuteNonQuery()
        myCommand.CommandText = "Insert into Test (id, desc) VALUES (101, 'Description')"
        myCommand.ExecuteNonQuery()
        myTrans.Commit()
        Console.WriteLine("Both records are written to database.")
    Catch e As Exception
        Try
            myTrans.Rollback()
        Catch ex As MySQLException
            If Not myTrans.Connection Is Nothing Then
                Console.WriteLine("An exception of type " + ex.GetType().ToString() + _
                    " was encountered while attempting to roll back the transaction.")
            End If
        End Try

        Console.WriteLine("An exception of type " + e.GetType().ToString() + _
            "was encountered while inserting the data.")
        Console.WriteLine("Neither record was written to database.")
    Finally
        myConnection.Close()
    End Try
End Sub
```

C# example:

```
public void RunTransaction(string myConnString)
{
    MySqlConnection myConnection = new MySqlConnection(myConnString);
    myConnection.Open();
    MySqlCommand myCommand = myConnection.CreateCommand();
    MySQLTransaction myTrans;
    // Start a local transaction
    myTrans = myConnection.BeginTransaction();
    // Must assign both transaction object and connection
    // to Command object for a pending local transaction
    myCommand.Connection = myConnection;
    myCommand.Transaction = myTrans;
    try
    {
        myCommand.CommandText = "insert into Test (id, desc) VALUES (100, 'Description')";
        myCommand.ExecuteNonQuery();
        myCommand.CommandText = "insert into Test (id, desc) VALUES (101, 'Description')";
        myCommand.ExecuteNonQuery();
        myTrans.Commit();
        Console.WriteLine("Both records are written to database.");
    }
    catch(Exception e)
```

```

{
    try
    {
        myTrans.Rollback();
    }
    catch (SqlException ex)
    {
        if (myTrans.Connection != null)
        {
            Console.WriteLine("An exception of type " + ex.GetType() +
                " was encountered while attempting to roll back the transaction.");
        }
    }

    Console.WriteLine("An exception of type " + e.GetType() +
        " was encountered while inserting the data.");
    Console.WriteLine("Neither record was written to database.");
}
finally
{
    myConnection.Close();
}
}

```

25.2.3.3.10. BeginTransaction1

Begins a database transaction with the specified isolation level.

Parameters: The isolation level under which the transaction should run.

Returns: An object representing the new transaction.

Exception: Parallel exceptions are not supported.

This command is equivalent to the MySQL BEGIN TRANSACTION command.

You must explicitly commit or roll back the transaction using the [MySQLTransaction.Commit](#) or [MySQLTransaction.Rollback](#) method.

Note. If you do not specify an isolation level, the default isolation level is used. To specify an isolation level with the [BeginTransaction](#) method, use the overload that takes the `iso` parameter.

Examples

The following example creates a [MySQLConnection](#) and a [MySQLTransaction](#). It also demonstrates how to use the [BeginTransaction](#), a [MySQLTransaction.Commit](#), and [MySQLTransaction.Rollback](#) methods.

Visual Basic example:

```

Public Sub RunTransaction(myConnString As String)
    Dim myConnection As New MySqlConnection(myConnString)
    myConnection.Open()

    Dim myCommand As MySqlCommand = myConnection.CreateCommand()
    Dim myTrans As MySQLTransaction

    ' Start a local transaction
    myTrans = myConnection.BeginTransaction()
    ' Must assign both transaction object and connection
    ' to Command object for a pending local transaction
    myCommand.Connection = myConnection
    myCommand.Transaction = myTrans

    Try
        myCommand.CommandText = "Insert into Test (id, desc) VALUES (100, 'Description')"
        myCommand.ExecuteNonQuery()
        myCommand.CommandText = "Insert into Test (id, desc) VALUES (101, 'Description')"
        myCommand.ExecuteNonQuery()
    
```

```

    myTrans.Commit()
    Console.WriteLine("Both records are written to database.")
Catch e As Exception
    Try
        myTrans.Rollback()
    Catch ex As MySqlException
        If Not myTrans.Connection Is Nothing Then
            Console.WriteLine("An exception of type " + ex.GetType().ToString() + _
                " was encountered while attempting to roll back the transaction.")
        End If
    End Try

    Console.WriteLine("An exception of type " + e.GetType().ToString() + _
        " was encountered while inserting the data.")
    Console.WriteLine("Neither record was written to database.")
Finally
    myConnection.Close()
End Try
End Sub

```

C# example:

```

public void RunTransaction(string myConnString)
{
    MySqlConnection myConnection = new MySqlConnection(myConnString);
    myConnection.Open();
    MySqlCommand myCommand = myConnection.CreateCommand();
    MySqlTransaction myTrans;
    // Start a local transaction
    myTrans = myConnection.BeginTransaction();
    // Must assign both transaction object and connection
    // to Command object for a pending local transaction
    myCommand.Connection = myConnection;
    myCommand.Transaction = myTrans;
    try
    {
        myCommand.CommandText = "insert into Test (id, desc) VALUES (100, 'Description')";
        myCommand.ExecuteNonQuery();
        myCommand.CommandText = "insert into Test (id, desc) VALUES (101, 'Description')";
        myCommand.ExecuteNonQuery();
        myTrans.Commit();
        Console.WriteLine("Both records are written to database.");
    }
    catch(Exception e)
    {
        try
        {
            myTrans.Rollback();
        }
        catch (SqlException ex)
        {
            if (myTrans.Connection != null)
            {
                Console.WriteLine("An exception of type " + ex.GetType() +
                    " was encountered while attempting to roll back the transaction.");
            }
        }

        Console.WriteLine("An exception of type " + e.GetType() +
            " was encountered while inserting the data.");
        Console.WriteLine("Neither record was written to database.");
    }
    finally
    {
        myConnection.Close();
    }
}

```

25.2.3.3.11. ChangeDatabase

Changes the current database for an open MySqlConnection.

Parameters: The name of the database to use.

The value supplied in the `database` parameter must be a valid database name. The `database` parameter cannot contain a null value, an empty string, or a string with only blank characters.

When you are using connection pooling against MySQL, and you close the connection, it is returned to the connection pool. The next time the connection is retrieved from the pool, the reset connection request executes before the user performs any operations.

Exception: The database name is not valid.

Exception: The connection is not open.

Exception: Cannot change the database.

Examples

The following example creates a `MySqlConnection` and displays some of its read-only properties.

Visual Basic example:

```
Public Sub CreateMySQLConnection()
    Dim myConnString As String = _
        "Persist Security Info=False;database=test;server=localhost;user id=joeuser;pwd=pass"
    Dim myConnection As New MySqlConnection( myConnString )
    myConnection.Open()
    MessageBox.Show( "Server Version: " + myConnection.ServerVersion _
        + ControlChars.NewLine + "Database: " + myConnection.Database )
    myConnection.ChangeDatabase( "test2" )
    MessageBox.Show( "ServerVersion: " + myConnection.ServerVersion _
        + ControlChars.NewLine + "Database: " + myConnection.Database )
    myConnection.Close()
End Sub
```

C# example:

```
public void CreateMySQLConnection()
{
    string myConnString =
        "Persist Security Info=False;database=test;server=localhost;user id=joeuser;pwd=pass";
    MySqlConnection myConnection = new MySqlConnection( myConnString );
    myConnection.Open();
    MessageBox.Show( "Server Version: " + myConnection.ServerVersion
        + "\nDatabase: " + myConnection.Database );
    myConnection.ChangeDatabase( "test2" );
    MessageBox.Show( "ServerVersion: " + myConnection.ServerVersion
        + "\nDatabase: " + myConnection.Database );
    myConnection.Close();
}
```

25.2.3.3.12. StateChange

Occurs when the state of the connection changes.

The `StateChange` event fires whenever the `State` changes from closed to opened, or from opened to closed. `StateChange` fires immediately after the `MySqlConnection` transitions.

If an event handler throws an exception from within the `StateChange` event, the exception propagates to the caller of the `Open` or `Close` method.

The `StateChange` event is not raised unless you explicitly call `Close` or `Dispose`.

The event handler receives an argument of type `System.Data.StateChangeEventArgs` containing data related to this event. The following `StateChangeEventArgs` properties provide information specific to this event.

Property	Description
<code>System.Data.StateChangeEventArgs.CurrentState</code>	Gets the new state of the connection. The connection object will be in the new state already when the event is fired.
<code>System.Data.StateChangeEventArgs.OriginalState</code>	Gets the original state of the connection.

25.2.3.3.13. InfoMessage

Occurs when MySQL returns warnings as a result of executing a command or query.

25.2.3.3.14. ConnectionTimeout

Gets the time to wait while trying to establish a connection before terminating the attempt and generating an error.

Exception: The value set is less than 0.

A value of 0 indicates no limit, and should be avoided in a `MySQLConnection.ConnectionString` because an attempt to connect will wait indefinitely.

Examples

The following example creates a `MySQLConnection` and sets some of its properties in the connection string.

Visual Basic example:

```
Public Sub CreateSqlConnection()
    Dim myConnection As New MySqlConnection()
    myConnection.ConnectionString = "Persist Security Info=False;Username=user;Password=pass;database=test"
    myConnection.Open()
End Sub
```

C# example:

```
public void CreateSqlConnection()
{
    MySqlConnection myConnection = new MySqlConnection();
    myConnection.ConnectionString = "Persist Security Info=False;Username=user;Password=pass;database=test";
    myConnection.Open();
}
```

25.2.3.3.15. ConnectionString

Gets or sets the string used to connect to a MySQL Server database.

The `ConnectionString` returned may not be exactly like what was originally set but will be identical in terms of keyword/value pairs. Security information will not be included unless the `Persist Security Info` value is set to true.

You can use the `ConnectionString` property to connect to a database. The following example illustrates a typical connection string.

```
"Persist Security Info=False;database=MyDB;server=MySQLServer;user id=myUser;Password=myPass"
```

The `ConnectionString` property can be set only when the connection is closed. Many of the connection string values have corresponding read-only properties. When the connection string is set, all of these properties are updated, except when an error is detected. In this case, none of the properties are updated. `MySQLConnection` properties return only those settings contained in the `ConnectionString`.

To connect to a local machine, specify "localhost" for the server. If you do not specify a server, localhost is assumed.

Resetting the `ConnectionString` on a closed connection resets all connection string values (and related properties) including the password. For example, if you set a connection string that includes "Database= MyDb", and then reset the connection string to "Data Source=myserver;UserId=myUser;Password=myPass", the `MySQLConnection.Database` property is no longer set to MyDb.

The connection string is parsed immediately after being set. If errors in syntax are found when parsing, a runtime exception, such as `ArgumentException`, is generated. Other errors can be found only when an attempt is made to open the connection.

The basic format of a connection string consists of a series of keyword/value pairs separated by semicolons. The equal sign (=) connects each keyword and its value. To include values that contain a semicolon, single-quote character, or double-quote character, the value must be enclosed in double quotes. If the value contains both a semicolon and a double-quote character, the value can be enclosed in single quotes. The single quote is also useful if the value begins with a double-quote character. Conversely, the double quote can be used if the value begins with a single quote. If the value contains both single-quote and double-quote characters, the quote character used to enclose the value must be doubled each time it occurs within the value.

To include preceding or trailing spaces in the string value, the value must be enclosed in either single quotes or double quotes. Any leading or trailing spaces around integer, Boolean, or enumerated values are ignored, even if enclosed in quotes. However, spaces within a string literal keyword or value are preserved. Using .NET Framework version 1.1, single or double quotes may be used within a connection string without using delimiters (for example, Data Source= my'Server or Data Source= my"Server), unless a quote character is the first or last character in the value.

To include an equal sign (=) in a keyword or value, it must be preceded by another equal sign. For example, in the hypothetical connection string

```
"key==word=value"
```

the keyword is "key=word" and the value is "value".

If a specific keyword in a keyword= value pair occurs multiple times in a connection string, the last occurrence listed is used in the value set.

Keywords are not case sensitive.

The following table lists the valid names for keyword values within the `ConnectionString`.

Name	Default	Description
Connect Timeout -or- Connection Timeout	15	The length of time (in seconds) to wait for a connection to the server before terminating the attempt and generating an error.
Host -or- Server -or- Data Source -or- DataSource -or- Address -or- Addr -or- Network Address	localhost	The name or network address of the instance of MySQL to which to connect. Multiple hosts can be

		specified separated by &. This can be useful where multiple MySQL servers are configured for replication and you are not concerned about the precise server you are connecting to. No attempt is made by the provider to synchronize writes to the database so care should be taken when using this option. In Unix environment with Mono, this can be a fully qualified path to MySQL socket filename. With this configuration, the Unix socket will be used instead of TCP/IP socket. Currently only a single socket name can be given so accessing MySQL in a replicated environment using Unix sockets is not currently supported.
Port	3306	The port MySQL is using to listen for connections. Specify -1 for this value to use a named pipe connection (Windows only). This value is ignored if Unix socket is used.
Protocol	socket	Specifies the type of connection to make to the server. Values can be: socket or tcp for a socket connection pipe for a named pipe connection unix for a Unix socket connection memory to use MySQL shared memory
CharSet -or Character Set		Specifies the character set that should be used to encode all queries sent to the server. Result-sets are still returned in the character set of the data returned.
Logging	false	When true, various pieces of information is output to any configured TraceListeners.
Allow Batch	true	When true, multiple SQL statements can be sent with one command execution. -Note- Starting with MySQL 4.1.1, batch statements should be separated by the server-defined separator character. Commands sent to earlier versions of MySQL should be separated with ';'.
Encrypt	false	When <code>true</code> , SSL encryption is used for all data sent between the client and server if the server has a certificate installed. Recognized values are <code>true</code> , <code>false</code> , <code>yes</code> ,

		and no . Note This parameter currently has no effect.
Initial Catalog -or- Database	mysql	The name of the database to use initially
Password -or- pwd		The password for the MySQL account being used.
Persist Security Info	false	When set to false or no (strongly recommended), security-sensitive information, such as the password, is not returned as part of the connection if the connection is open or has ever been in an open state. Resetting the connection string resets all connection string values including the password. Recognized values are true , false , yes , and no .
User Id -or- Username -or- Uid -or- User name		The MySQL login account being used.
Shared Memory Name	MYSQL	The name of the shared memory object to use for communication if the connection protocol is set to memory.
Allow Zero Datetime	false	True to have MySqlDataReader.GetValue() return a MySqlDateTime for date or datetime columns that have illegal values. False will cause a DateTime object to be returned for legal values and an exception will be thrown for illegal values.
Convert Zero Datetime	false	True to have MySqlDataReader.GetValue() and MySqlDataReader.GetDateTime() return DateTime.MinValue for date or datetime columns that have illegal values.
Old Syntax -or- OldSyntax	false	Allows use of '@' symbol as a parameter marker. See MySQL-Command for more info. This is for compatibility only. All future code should be written to use the new '?' parameter marker.
Pipe Name -or- Pipe	mysql	When set to the name of a named pipe, the MySQLConnection will attempt to connect to MySQL on that named pipe. This settings only applies to the Windows platform.

The following table lists the valid names for connection pooling values within the [ConnectionString](#). For more information about connection pooling, see [Connection Pooling for the MySQL Data](#)

Provider.

Name	Default	Description
Connection Lifetime	0	When a connection is returned to the pool, its creation time is compared with the current time, and the connection is destroyed if that time span (in seconds) exceeds the value specified by <code>Connection Lifetime</code> . This is useful in clustered configurations to force load balancing between a running server and a server just brought online. A value of zero (0) causes pooled connections to have the maximum connection timeout.
Max Pool Size	100	The maximum number of connections allowed in the pool.
Min Pool Size	0	The minimum number of connections allowed in the pool.
Pooling	true	When <code>true</code> , the <code>MySQLConnection</code> object is drawn from the appropriate pool, or if necessary, is created and added to the appropriate pool. Recognized values are <code>true</code> , <code>false</code> , <code>yes</code> , and <code>no</code> .
Reset Pooled Connections -or- ResetConnections -or- Reset- PooledConnections	true	Specifies whether a ping and a reset should be sent to the server before a pooled connection is returned. Not resetting will yeild faster connection opens but also will not clear out session items such as temp tables.
Cache Server Configuration -or- CacheServerConfiguration -or- CacheServerConfig	false	Specifies whether server variables should be updated when a pooled connection is returned. Turning this one will yeild faster opens but will also not catch any server changes made by other connections.

When setting keyword or connection pooling values that require a Boolean value, you can use 'yes' instead of 'true', and 'no' instead of 'false'.

Note The MySQL Data Provider uses the native socket protocol to communicate with MySQL. Therefore, it does not support the use of an ODBC data source name (DSN) when connecting to MySQL because it does not add an ODBC layer.

CAUTION In this release, the application should use caution when constructing a connection string based on user input (for example when retrieving user ID and password information from a dialog box, and appending it to the connection string). The application should ensure that a user cannot embed extra connection string parameters in these values (for example, entering a password as "validpassword;database=somedb" in an attempt to attach to a different database).

Examples

The following example creates a [MySQLConnection](#) and sets some of its properties

Visual Basic example:

```
Public Sub CreateConnection()
    Dim myConnection As New MySqlConnection()
    myConnection.ConnectionString = "Persist Security Info=False;database=myDB;server=myHost;Connect T
    myConnection.Open()
End Sub 'CreateConnection
```

C# example:

```
public void CreateConnection()
{
    MySqlConnection myConnection = new MySqlConnection();
    myConnection.ConnectionString = "Persist Security Info=False;database=myDB;server=myHost;Connect T
    myConnection.Open();
}
```

Examples

The following example creates a [MySQLConnection](#) in Unix environment with Mono installed. MySQL socket filename used in this example is `"/var/lib/mysql/mysql.sock"`. The actual filename depends on your MySQL configuration.

Visual Basic example:

```
Public Sub CreateConnection()
    Dim myConnection As New MySqlConnection()
    myConnection.ConnectionString = "database=myDB;server=/var/lib/mysql/mysql.sock;user id=myUser; pwo
    myConnection.Open()
End Sub 'CreateConnection
```

C# example:

```
public void CreateConnection()
{
    MySqlConnection myConnection = new MySqlConnection();
    myConnection.ConnectionString = "database=myDB;server=/var/lib/mysql/mysql.sock;user id=myUser; pwo
    myConnection.Open();
}
```

25.2.3.4. MySqlConnectionDataAdapter

Represents a set of data commands and a database connection that are used to fill a dataset and update a MySQL database. This class cannot be inherited.

The [MySQLDataAdapter](#), serves as a bridge between a [System.Data.DataSet](#) and MySQL for retrieving and saving data. The [MySQLDataAdapter](#) provides this bridge by mapping [DbDataAdapter.Fill](#), which changes the data in the [DataSet](#) to match the data in the data source, and [DbDataAdapter.Update](#), which changes the data in the data source to match the data in the [DataSet](#), using the appropriate SQL statements against the data source.

When the [MySQLDataAdapter](#) fills a [DataSet](#), it will create the necessary tables and columns for the returned data if they do not already exist. However, primary key information will not be included in the implicitly created schema unless the [System.Data.MissingSchemaAction](#) property is set to [System.Data.MissingSchemaAction.AddWithKey](#). You may also have the

`MySQLDataAdapter` create the schema of the `DataSet`, including primary key information, before filling it with data using `System.Data.Common.DbDataAdapter.FillSchema`.

`MySQLDataAdapter` is used in conjunction with `MySqlConnection` and `MySqlCommand` to increase performance when connecting to a MySQL database.

The `MySQLDataAdapter` also includes the `MySqlCommand.SelectCommand`, `MySqlCommand.InsertCommand`, `MySqlCommand.DeleteCommand`, `MySqlCommand.UpdateCommand`, and `DataAdapter.TableMappings` properties to facilitate the loading and updating of data.

When an instance of `MySQLDataAdapter` is created, the read/write properties are set to initial values. For a list of these values, see the `MySQLDataAdapter` constructor.

Note. Please be aware that the `DataColumn` class in .NET 1.0 and 1.1 does not allow columns with type of `UInt16`, `UInt32`, or `UInt64` to be autoincrement columns. If you plan to use autoincrement columns with MySQL, you should consider using signed integer columns.

Examples

The following example creates a `MySqlCommand` and a `MySqlConnection`. The `MySqlConnection` is opened and set as the `MySqlCommand.Connection` for the `MySqlCommand`. The example then calls `MySqlCommand.ExecuteNonQuery`, and closes the connection. To accomplish this, the `ExecuteNonQuery` is passed a connection string and a query string that is a SQL INSERT statement.

Visual Basic example:

```
Public Function SelectRows(dataSet As DataSet, connection As String, query As String) As DataSet
    Dim conn As New MySqlConnection(connection)
    Dim adapter As New MySQLDataAdapter()
    adapter.SelectCommand = new MySqlCommand(query, conn)
    adapter.Fill(dataset)
    Return dataset
End Function
```

C# example:

```
public DataSet SelectRows(DataSet dataset,string connection,string query)
{
    MySqlConnection conn = new MySqlConnection(connection);
    MySQLDataAdapter adapter = new MySQLDataAdapter();
    adapter.SelectCommand = new MySqlCommand(query, conn);
    adapter.Fill(dataset);
    return dataset;
}
```

25.2.3.4.1. Class `MySqlCommand` Constructor

Overload methods for `MySqlCommand`

Initializes a new instance of the `MySqlCommand` class.

When an instance of `MySqlCommand` is created, the following read/write properties are set to the following initial values.

Properties	Initial Value
<code>MissingMappingAction</code>	<code>MissingMappingAction.Passthrough</code>
<code>MissingSchemaAction</code>	<code>MissingSchemaAction.Add</code>

You can change the value of any of these properties through a separate call to the property.

Examples

The following example creates a [MySQLDataAdapter](#) and sets some of its properties.

Visual Basic example:

```
Public Sub CreateSqlDataAdapter()
    Dim conn As MySqlConnection = New MySqlConnection("Data Source=localhost;" & _
        "database=test")
    Dim da As MySQLDataAdapter = New MySQLDataAdapter
    da.MissingSchemaAction = MissingSchemaAction.AddWithKey

    da.SelectCommand = New MySqlCommand("SELECT id, name FROM mytable", conn)
    da.InsertCommand = New MySqlCommand("INSERT INTO mytable (id, name) " & _
        "VALUES (?id, ?name)", conn)
    da.UpdateCommand = New MySqlCommand("UPDATE mytable SET id=?id, name=?name " & _
        "WHERE id=?oldId", conn)
    da.DeleteCommand = New MySqlCommand("DELETE FROM mytable WHERE id=?id", conn)
    da.InsertCommand.Parameters.Add("?id", MySqlDbType.VarChar, 5, "id")
    da.InsertCommand.Parameters.Add("?name", MySqlDbType.VarChar, 40, "name")

    da.UpdateCommand.Parameters.Add("?id", MySqlDbType.VarChar, 5, "id")
    da.UpdateCommand.Parameters.Add("?name", MySqlDbType.VarChar, 40, "name")
    da.UpdateCommand.Parameters.Add("?oldId", MySqlDbType.VarChar, 5, "id").SourceVersion = DataRowVersion.Original
    da.DeleteCommand.Parameters.Add("?id", MySqlDbType.VarChar, 5, "id").SourceVersion = DataRowVersion.Original
End Sub
```

C# example:

```
public static void CreateSqlDataAdapter()
{
    MySqlConnection conn = new MySqlConnection("Data Source=localhost;database=test");
    MySQLDataAdapter da = new MySQLDataAdapter();
    da.MissingSchemaAction = MissingSchemaAction.AddWithKey;

    da.SelectCommand = new MySqlCommand("SELECT id, name FROM mytable", conn);
    da.InsertCommand = new MySqlCommand("INSERT INTO mytable (id, name) " +
        "VALUES (?id, ?name)", conn);
    da.UpdateCommand = new MySqlCommand("UPDATE mytable SET id=?id, name=?name " +
        "WHERE id=?oldId", conn);
    da.DeleteCommand = new MySqlCommand("DELETE FROM mytable WHERE id=?id", conn);
    da.InsertCommand.Parameters.Add("?id", MySqlDbType.VarChar, 5, "id");
    da.InsertCommand.Parameters.Add("?name", MySqlDbType.VarChar, 40, "name");

    da.UpdateCommand.Parameters.Add("?id", MySqlDbType.VarChar, 5, "id");
    da.UpdateCommand.Parameters.Add("?name", MySqlDbType.VarChar, 40, "name");
    da.UpdateCommand.Parameters.Add("?oldId", MySqlDbType.VarChar, 5, "id").SourceVersion = DataRowVersion.Original
    da.DeleteCommand.Parameters.Add("?id", MySqlDbType.VarChar, 5, "id").SourceVersion = DataRowVersion.Original
}
```

25.2.3.4.2. Class MySQLDataAdapter Constructor Form 1

Initializes a new instance of the [MySQLDataAdapter](#) class with the specified [MySQLCommand](#) as the [SelectCommand](#) property.

Parameters: [MySQLCommand](#) that is a SQL [SELECT](#) statement or stored procedure and is set as the [SelectCommand](#) property of the [MySQLDataAdapter](#).

When an instance of [MySQLDataAdapter](#) is created, the following read/write properties are set to the following initial values.

Properties	Initial Value
MissingMappingAction	MissingMappingAction.Passthrough
MissingSchemaAction	MissingSchemaAction.Add

You can change the value of any of these properties through a separate call to the property.

When [SelectCommand](#) (or any of the other command properties) is assigned to a previously created [MySQLCommand](#), the [MySQLCommand](#) is not cloned. The [SelectCommand](#) maintains a reference to the previously created [MySQLCommand](#) object.

Examples

The following example creates a [MySQLDataAdapter](#) and sets some of its properties.

Visual Basic example:

```
Public Sub CreateSqlDataAdapter()
    Dim conn As MySqlConnection = New MySqlConnection("Data Source=localhost;" & _
        "database=test")
    Dim cmd as new MySqlCommand("SELECT id, name FROM mytable", conn)
    Dim da As MySQLDataAdapter = New MySQLDataAdapter(cmd)
    da.MissingSchemaAction = MissingSchemaAction.AddWithKey

    da.InsertCommand = New MySqlCommand("INSERT INTO mytable (id, name) " & _
        "VALUES (?id, ?name)", conn)
    da.UpdateCommand = New MySqlCommand("UPDATE mytable SET id=?id, name=?name " & _
        "WHERE id=?oldId", conn)
    da.DeleteCommand = New MySqlCommand("DELETE FROM mytable WHERE id=?id", conn)
    da.InsertCommand.Parameters.Add("?id", MySqlDbType.VarChar, 5, "id")
    da.InsertCommand.Parameters.Add("?name", MySqlDbType.VarChar, 40, "name")

    da.UpdateCommand.Parameters.Add("?id", MySqlDbType.VarChar, 5, "id")
    da.UpdateCommand.Parameters.Add("?name", MySqlDbType.VarChar, 40, "name")
    da.UpdateCommand.Parameters.Add("?oldId", MySqlDbType.VarChar, 5, "id").SourceVersion = DataRowVersion.Current
    da.DeleteCommand.Parameters.Add("?id", MySqlDbType.VarChar, 5, "id").SourceVersion = DataRowVersion.Current
End Sub
```

C# example:

```
public static void CreateSqlDataAdapter()
{
    MySqlConnection conn = new MySqlConnection("Data Source=localhost;database=test");
    MySqlCommand cmd = new MySqlCommand("SELECT id, name FROM mytable", conn);
    MySQLDataAdapter da = new MySQLDataAdapter(cmd);
    da.MissingSchemaAction = MissingSchemaAction.AddWithKey;

    da.InsertCommand = new MySqlCommand("INSERT INTO mytable (id, name) " +
        "VALUES (?id, ?name)", conn);
    da.UpdateCommand = new MySqlCommand("UPDATE mytable SET id=?id, name=?name " +
        "WHERE id=?oldId", conn);
    da.DeleteCommand = new MySqlCommand("DELETE FROM mytable WHERE id=?id", conn);
    da.InsertCommand.Parameters.Add("?id", MySqlDbType.VarChar, 5, "id");
    da.InsertCommand.Parameters.Add("?name", MySqlDbType.VarChar, 40, "name");

    da.UpdateCommand.Parameters.Add("?id", MySqlDbType.VarChar, 5, "id");
    da.UpdateCommand.Parameters.Add("?name", MySqlDbType.VarChar, 40, "name");
    da.UpdateCommand.Parameters.Add("?oldId", MySqlDbType.VarChar, 5, "id").SourceVersion = DataRowVersion.Current;
    da.DeleteCommand.Parameters.Add("?id", MySqlDbType.VarChar, 5, "id").SourceVersion = DataRowVersion.Current;
}
```

25.2.3.4.3. Class MySQLDataAdapter Constructor Form 2

Initializes a new instance of the [MySQLDataAdapter](#) class with a [SelectCommand](#) and a [MySQLConnection](#) object.

Parameters: A [String](#) that is a SQL [SELECT](#) statement or stored procedure to be used by the [SelectCommand](#) property of the [MySQLDataAdapter](#).

Parameters: A [MySQLConnection](#) that represents the connection.

This implementation of the [MySQLDataAdapter](#) opens and closes a [MySQLConnection](#) if it is not

already open. This can be useful in an application that must call the `DbDataAdapter.Fill` method for two or more `MySqlConnection` objects. If the `MySqlConnection` is already open, you must explicitly call `MySqlConnection.Close` or `MySqlConnection.Dispose` to close it.

When an instance of `MySqlConnection` is created, the following read/write properties are set to the following initial values.

Properties	Initial Value
<code>MissingMappingAction</code>	<code>MissingMappingAction.Passthrough</code>
<code>MissingSchemaAction</code>	<code>MissingSchemaAction.Add</code>

You can change the value of any of these properties through a separate call to the property.

Examples

The following example creates a `MySqlConnection` and sets some of its properties.

Visual Basic example:

```
Public Sub CreateSqlConnection()
    Dim conn As MySqlConnection = New MySqlConnection("Data Source=localhost;" & _
        "database=test")
    Dim da As MySqlDataAdapter = New MySqlDataAdapter("SELECT id, name FROM mytable", conn)
    da.MissingSchemaAction = MissingSchemaAction.AddWithKey

    da.InsertCommand = New MySqlCommand("INSERT INTO mytable (id, name) " & _
        "VALUES (?id, ?name)", conn)
    da.UpdateCommand = New MySqlCommand("UPDATE mytable SET id=?id, name=?name " & _
        "WHERE id=?oldId", conn)
    da.DeleteCommand = New MySqlCommand("DELETE FROM mytable WHERE id=?id", conn)
    da.InsertCommand.Parameters.Add("?id", MySqlDbType.VarChar, 5, "id")
    da.InsertCommand.Parameters.Add("?name", MySqlDbType.VarChar, 40, "name")

    da.UpdateCommand.Parameters.Add("?id", MySqlDbType.VarChar, 5, "id")
    da.UpdateCommand.Parameters.Add("?name", MySqlDbType.VarChar, 40, "name")
    da.UpdateCommand.Parameters.Add("?oldId", MySqlDbType.VarChar, 5, "id").SourceVersion = DataRowVersion.Original
    da.DeleteCommand.Parameters.Add("?id", MySqlDbType.VarChar, 5, "id").SourceVersion = DataRowVersion.Original
End Sub
```

C# example:

```
public static void CreateSqlConnection()
{
    MySqlConnection conn = new MySqlConnection("Data Source=localhost;database=test");
    MySqlDataAdapter da = new MySqlDataAdapter("SELECT id, name FROM mytable", conn);
    da.MissingSchemaAction = MissingSchemaAction.AddWithKey;

    da.InsertCommand = new MySqlCommand("INSERT INTO mytable (id, name) " +
        "VALUES (?id, ?name)", conn);
    da.UpdateCommand = new MySqlCommand("UPDATE mytable SET id=?id, name=?name " +
        "WHERE id=?oldId", conn);
    da.DeleteCommand = new MySqlCommand("DELETE FROM mytable WHERE id=?id", conn);
    da.InsertCommand.Parameters.Add("?id", MySqlDbType.VarChar, 5, "id");
    da.InsertCommand.Parameters.Add("?name", MySqlDbType.VarChar, 40, "name");

    da.UpdateCommand.Parameters.Add("?id", MySqlDbType.VarChar, 5, "id");
    da.UpdateCommand.Parameters.Add("?name", MySqlDbType.VarChar, 40, "name");
    da.UpdateCommand.Parameters.Add("?oldId", MySqlDbType.VarChar, 5, "id").SourceVersion = DataRowVersion.Original;
    da.DeleteCommand.Parameters.Add("?id", MySqlDbType.VarChar, 5, "id").SourceVersion = DataRowVersion.Original;
}
```

25.2.3.4.4. Class MySqlConnection Constructor Form 3

Initializes a new instance of the `MySqlConnection` class with a `SelectCommand` and a connection string.

Parameters: A [string](#) that is a SQL [SELECT](#) statement or stored procedure to be used by the [SelectCommand](#) property of the [MySqlDataAdapter](#).

Parameters: The connection string

When an instance of [MySqlDataAdapter](#) is created, the following read/write properties are set to the following initial values.

Properties	Initial Value
MissingMappingAction	MissingMappingAction.Passthrough
MissingSchemaAction	MissingSchemaAction.Add

You can change the value of any of these properties through a separate call to the property.

Examples

The following example creates a [MySqlDataAdapter](#) and sets some of its properties.

Visual Basic example:

```
Public Sub CreateSqlDataAdapter()
    Dim da As MySqlDataAdapter = New MySqlDataAdapter("SELECT id, name FROM mytable", "Data Source=localhost;")
    Dim conn As MySqlConnection = da.SelectCommand.Connection
    da.MissingSchemaAction = MissingSchemaAction.AddWithKey

    da.InsertCommand = New MySqlCommand("INSERT INTO mytable (id, name) " & _
        "VALUES (?id, ?name)", conn)
    da.UpdateCommand = New MySqlCommand("UPDATE mytable SET id=?id, name=?name " & _
        "WHERE id=?oldId", conn)
    da.DeleteCommand = New MySqlCommand("DELETE FROM mytable WHERE id=?id", conn)
    da.InsertCommand.Parameters.Add("?id", MySqlDbType.VarChar, 5, "id")
    da.InsertCommand.Parameters.Add("?name", MySqlDbType.VarChar, 40, "name")

    da.UpdateCommand.Parameters.Add("?id", MySqlDbType.VarChar, 5, "id")
    da.UpdateCommand.Parameters.Add("?name", MySqlDbType.VarChar, 40, "name")
    da.UpdateCommand.Parameters.Add("?oldId", MySqlDbType.VarChar, 5, "id").SourceVersion = DataRowVersion.Current
    da.DeleteCommand.Parameters.Add("?id", MySqlDbType.VarChar, 5, "id").SourceVersion = DataRowVersion.Current
End Sub
```

C# example:

```
public static void CreateSqlDataAdapter()
{
    MySqlDataAdapter da = new MySqlDataAdapter("SELECT id, name FROM mytable", "Data Source=localhost;");
    MySqlConnection conn = da.SelectCommand.Connection;
    da.MissingSchemaAction = MissingSchemaAction.AddWithKey;

    da.InsertCommand = new MySqlCommand("INSERT INTO mytable (id, name) " +
        "VALUES (?id, ?name)", conn);
    da.UpdateCommand = new MySqlCommand("UPDATE mytable SET id=?id, name=?name " +
        "WHERE id=?oldId", conn);
    da.DeleteCommand = new MySqlCommand("DELETE FROM mytable WHERE id=?id", conn);
    da.InsertCommand.Parameters.Add("?id", MySqlDbType.VarChar, 5, "id");
    da.InsertCommand.Parameters.Add("?name", MySqlDbType.VarChar, 40, "name");

    da.UpdateCommand.Parameters.Add("?id", MySqlDbType.VarChar, 5, "id");
    da.UpdateCommand.Parameters.Add("?name", MySqlDbType.VarChar, 40, "name");
    da.UpdateCommand.Parameters.Add("?oldId", MySqlDbType.VarChar, 5, "id").SourceVersion = DataRowVersion.Current;
    da.DeleteCommand.Parameters.Add("?id", MySqlDbType.VarChar, 5, "id").SourceVersion = DataRowVersion.Current;
}
```

25.2.3.4.5. DeleteCommand

Gets or sets a SQL statement or stored procedure used to delete records from the data set.

Value: A `MySqlCommand` used during `System.Data.Common.DataAdapter.Update` to delete records in the database that correspond to deleted rows in the `DataSet`.

During `System.Data.Common.DataAdapter.Update`, if this property is not set and primary key information is present in the `DataSet`, the `DeleteCommand` can be generated automatically if you set the `SelectCommand` property and use the `MySqlCommandBuilder`. Then, any additional commands that you do not set are generated by the `MySqlCommandBuilder`. This generation logic requires key column information to be present in the `DataSet`.

When `DeleteCommand` is assigned to a previously created `MySqlCommand`, the `MySqlCommand` is not cloned. The `DeleteCommand` maintains a reference to the previously created `MySqlCommand` object.

Examples

The following example creates a `MySqlDataAdapter` and sets the `SelectCommand` and `DeleteCommand` properties. It assumes you have already created a `MySqlConnection` object.

Visual Basic example:

```
Public Shared Function CreateCustomerAdapter(conn As MySqlConnection) As MySqlDataAdapter
    Dim da As MySqlDataAdapter = New MySqlDataAdapter()
    Dim cmd As MySqlCommand
    Dim parm As MySqlParameter
    ' Create the SelectCommand.
    cmd = New MySqlCommand("SELECT * FROM mytable WHERE id=?id AND name=?name", conn)
    cmd.Parameters.Add("?id", MySqlDbType.VarChar, 15)
    cmd.Parameters.Add("?name", MySqlDbType.VarChar, 15)
    da.SelectCommand = cmd
    ' Create the DeleteCommand.
    cmd = New MySqlCommand("DELETE FROM mytable WHERE id=?id", conn)
    parm = cmd.Parameters.Add("?id", MySqlDbType.VarChar, 5, "id")
    parm.SourceVersion = DataRowVersion.Original
    da.DeleteCommand = cmd
    Return da
End Function
```

C# example:

```
public static MySqlDataAdapter CreateCustomerAdapter(MySqlConnection conn)
{
    MySqlDataAdapter da = new MySqlDataAdapter();
    MySqlCommand cmd;
    MySqlParameter parm;
    // Create the SelectCommand.
    cmd = new MySqlCommand("SELECT * FROM mytable WHERE id=?id AND name=?name", conn);
    cmd.Parameters.Add("?id", MySqlDbType.VarChar, 15);
    cmd.Parameters.Add("?name", MySqlDbType.VarChar, 15);
    da.SelectCommand = cmd;
    // Create the DeleteCommand.
    cmd = new MySqlCommand("DELETE FROM mytable WHERE id=?id", conn);
    parm = cmd.Parameters.Add("?id", MySqlDbType.VarChar, 5, "id");
    parm.SourceVersion = DataRowVersion.Original;
    da.DeleteCommand = cmd;
    return da;
}
```

25.2.3.4.6. InsertCommand

Gets or sets a SQL statement or stored procedure used to insert records into the data set.

Value: A `MySqlCommand` used during `System.Data.Common.DataAdapter.Update` to insert records into the database that correspond to new rows in the `DataSet`.

During `System.Data.Common.DataAdapter.Update`, if this property is not set and primary

key information is present in the [DataSet](#), the [InsertCommand](#) can be generated automatically if you set the [SelectCommand](#) property and use the [MySQLCommandBuilder](#). Then, any additional commands that you do not set are generated by the [MySQLCommandBuilder](#). This generation logic requires key column information to be present in the [DataSet](#).

When [InsertCommand](#) is assigned to a previously created [MySQLCommand](#), the [MySQLCommand](#) is not cloned. The [InsertCommand](#) maintains a reference to the previously created [MySQLCommand](#) object.

Note. If execution of this command returns rows, these rows may be added to the [DataSet](#) depending on how you set the [MySQLCommand.UpdatedRowSource](#) property of the [MySQLCommand](#) object.

Examples

The following example creates a [MySQLDataAdapter](#) and sets the [SelectCommand](#) and [InsertCommand](#) properties. It assumes you have already created a [MySQLConnection](#) object.

Visual Basic example:

```
Public Shared Function CreateCustomerAdapter(conn As MySqlConnection) As MySQLDataAdapter
    Dim da As MySQLDataAdapter = New MySQLDataAdapter()
    Dim cmd As MySQLCommand
    Dim parm As MySQLParameter
    ' Create the SelectCommand.
    cmd = New MySQLCommand("SELECT * FROM mytable WHERE id=?id AND name=?name", conn)
    cmd.Parameters.Add("?id", MySQLDbType.VarChar, 15)
    cmd.Parameters.Add("?name", MySQLDbType.VarChar, 15)
    da.SelectCommand = cmd
    ' Create the InsertCommand.
    cmd = New MySQLCommand("INSERT INTO mytable (id,name) VALUES (?id, ?name)", conn)
    cmd.Parameters.Add( "?id", MySQLDbType.VarChar, 15, "id" )
    cmd.Parameters.Add( "?name", MySQLDbType.VarChar, 15, "name" )
    da.InsertCommand = cmd

    Return da
End Function
```

C# example:

```
public static MySQLDataAdapter CreateCustomerAdapter(MySqlConnection conn)
{
    MySQLDataAdapter da = new MySQLDataAdapter();
    MySQLCommand cmd;
    MySQLParameter parm;
    // Create the SelectCommand.
    cmd = new MySQLCommand("SELECT * FROM mytable WHERE id=?id AND name=?name", conn);
    cmd.Parameters.Add("?id", MySQLDbType.VarChar, 15);
    cmd.Parameters.Add("?name", MySQLDbType.VarChar, 15);
    da.SelectCommand = cmd;
    // Create the InsertCommand.
    cmd = new MySQLCommand("INSERT INTO mytable (id,name) VALUES (?id,?name)", conn);
    cmd.Parameters.Add("?id", MySQLDbType.VarChar, 15, "id" );
    cmd.Parameters.Add("?name", MySQLDbType.VarChar, 15, "name" );

    da.InsertCommand = cmd;
    return da;
}
```

25.2.3.4.7. UpdateCommand

Gets or sets a SQL statement or stored procedure used to updated records in the data source.

Value: A [MySQLCommand](#) used during [System.Data.Common.DataAdapter.Update](#) to update records in the database with data from the [DataSet](#).

During [System.Data.Common.DataAdapter.Update](#), if this property is not set and primary key information is present in the [DataSet](#), the [UpdateCommand](#) can be generated automatically if

you set the `SelectCommand` property and use the `MySQLCommandBuilder`. Then, any additional commands that you do not set are generated by the `MySQLCommandBuilder`. This generation logic requires key column information to be present in the `DataSet`.

When `UpdateCommand` is assigned to a previously created `MySQLCommand`, the `MySQLCommand` is not cloned. The `UpdateCommand` maintains a reference to the previously created `MySQLCommand` object.

Note. If execution of this command returns rows, these rows may be merged with the `DataSet` depending on how you set the `MySQLCommand.UpdatedRowSource` property of the `MySQLCommand` object.

Examples

The following example creates a `MySQLDataAdapter` and sets the `SelectCommand` and `UpdateCommand` properties. It assumes you have already created a `MySQLConnection` object.

Visual Basic example:

```
Public Shared Function CreateCustomerAdapter(conn As MySqlConnection) As MySQLDataAdapter
    Dim da As MySQLDataAdapter = New MySQLDataAdapter()
    Dim cmd As MySQLCommand
    Dim parm As MySQLParameter
    ' Create the SelectCommand.
    cmd = New MySQLCommand("SELECT * FROM mytable WHERE id=?id AND name=?name", conn)
    cmd.Parameters.Add("?id", MySQLDbType.VarChar, 15)
    cmd.Parameters.Add("?name", MySQLDbType.VarChar, 15)
    da.SelectCommand = cmd
    ' Create the UpdateCommand.
    cmd = New MySQLCommand("UPDATE mytable SET id=?id, name=?name WHERE id=?oldId", conn)
    cmd.Parameters.Add("?id", MySQLDbType.VarChar, 15, "id" )
    cmd.Parameters.Add("?name", MySQLDbType.VarChar, 15, "name" )

    parm = cmd.Parameters.Add("?oldId", MySQLDbType.VarChar, 15, "id")
    parm.SourceVersion = DataRowVersion.Original

    da.UpdateCommand = cmd

    Return da
End Function
```

C# example:

```
public static MySQLDataAdapter CreateCustomerAdapter(MySqlConnection conn)
{
    MySQLDataAdapter da = new MySQLDataAdapter();
    MySQLCommand cmd;
    MySQLParameter parm;
    // Create the SelectCommand.
    cmd = new MySQLCommand("SELECT * FROM mytable WHERE id=?id AND name=?name", conn);
    cmd.Parameters.Add("?id", MySQLDbType.VarChar, 15);
    cmd.Parameters.Add("?name", MySQLDbType.VarChar, 15);
    da.SelectCommand = cmd;
    // Create the UpdateCommand.
    cmd = new MySQLCommand("UPDATE mytable SET id=?id, name=?name WHERE id=?oldId", conn);
    cmd.Parameters.Add("?id", MySQLDbType.VarChar, 15, "id" );
    cmd.Parameters.Add("?name", MySQLDbType.VarChar, 15, "name" );

    parm = cmd.Parameters.Add( "?oldId", MySQLDbType.VarChar, 15, "id" );
    parm.SourceVersion = DataRowVersion.Original;

    da.UpdateCommand = cmd;
    return da;
}
```

25.2.3.4.8. SelectCommand

Gets or sets a SQL statement or stored procedure used to select records in the data source.

Value: A `MySQLCommand` used during `System.Data.Common.DbDataAdapter.Fill` to select records from the database for placement in the `DataSet`.

When `SelectCommand` is assigned to a previously created `MySQLCommand`, the `MySQLCommand` is not cloned. The `SelectCommand` maintains a reference to the previously created `MySQLCommand` object.

If the `SelectCommand` does not return any rows, no tables are added to the `DataSet`, and no exception is raised.

Examples

The following example creates a `MySQLDataAdapter` and sets the `SelectCommand` and `InsertCommand` properties. It assumes you have already created a `MySQLConnection` object.

Visual Basic example:

```
Public Shared Function CreateCustomerAdapter(conn As MySQLConnection) As MySQLDataAdapter
    Dim da As MySQLDataAdapter = New MySQLDataAdapter()
    Dim cmd As MySQLCommand
    Dim parm As MySQLParameter
    ' Create the SelectCommand.
    cmd = New MySQLCommand("SELECT * FROM mytable WHERE id=?id AND name=?name", conn)
    cmd.Parameters.Add("?id", MySQLDbType.VarChar, 15)
    cmd.Parameters.Add("?name", MySQLDbType.VarChar, 15)
    da.SelectCommand = cmd
    ' Create the InsertCommand.
    cmd = New MySQLCommand("INSERT INTO mytable (id,name) VALUES (?id, ?name)", conn)
    cmd.Parameters.Add( "?id", MySQLDbType.VarChar, 15, "id" )
    cmd.Parameters.Add( "?name", MySQLDbType.VarChar, 15, "name" )
    da.InsertCommand = cmd

    Return da
End Function
```

C# example:

```
public static MySQLDataAdapter CreateCustomerAdapter(MySQLConnection conn)
{
    MySQLDataAdapter da = new MySQLDataAdapter();
    MySQLCommand cmd;
    MySQLParameter parm;
    // Create the SelectCommand.
    cmd = new MySQLCommand("SELECT * FROM mytable WHERE id=?id AND name=?name", conn);
    cmd.Parameters.Add("?id", MySQLDbType.VarChar, 15);
    cmd.Parameters.Add("?name", MySQLDbType.VarChar, 15);
    da.SelectCommand = cmd;
    // Create the InsertCommand.
    cmd = new MySQLCommand("INSERT INTO mytable (id,name) VALUES (?id,?name)", conn);
    cmd.Parameters.Add("?id", MySQLDbType.VarChar, 15, "id" );
    cmd.Parameters.Add("?name", MySQLDbType.VarChar, 15, "name" );

    da.InsertCommand = cmd;
    return da;
}
```

25.2.3.5. MySQLDataReader

To create a `MySQLDataReader`, you must call the `MySQLCommand.ExecuteReader` method of the `MySQLCommand` object, rather than directly using a constructor.

While the `MySQLDataReader` is in use, the associated `MySQLConnection` is busy serving the `MySQLDataReader`, and no other operations can be performed on the `MySQLConnection` other than closing it. This is the case until the `MySQLDataReader.Close` method of the `MySQLDataReader` is called.

`MySqlDataReader.IsClosed` and `MySqlDataReader.RecordsAffected` are the only properties that you can call after the `MySqlDataReader` is closed. Though the `RecordsAffected` property may be accessed at any time while the `MySqlDataReader` exists, always call `Close` before returning the value of `RecordsAffected` to ensure an accurate return value.

For optimal performance, `MySqlDataReader` avoids creating unnecessary objects or making unnecessary copies of data. As a result, multiple calls to methods such as `MySqlDataReader.GetValue` return a reference to the same object. Use caution if you are modifying the underlying value of the objects returned by methods such as `GetValue`.

Examples

The following example creates a `MySqlConnection`, a `MySqlCommand`, and a `MySqlDataReader`. The example reads through the data, writing it out to the console. Finally, the example closes the `MySqlDataReader`, then the `MySqlConnection`.

Visual Basic example:

```
Public Sub ReadMyData(myConnString As String)
    Dim mySelectQuery As String = "SELECT OrderID, CustomerID FROM Orders"
    Dim myConnection As New MySqlConnection(myConnString)
    Dim myCommand As New MySqlCommand(mySelectQuery, myConnection)
    myConnection.Open()
    Dim myReader As MySqlDataReader
    myReader = myCommand.ExecuteReader()
    ' Always call Read before accessing data.
    While myReader.Read()
        Console.WriteLine((myReader.GetInt32(0) & ", " & myReader.GetString(1)))
    End While
    ' always call Close when done reading.
    myReader.Close()
    ' Close the connection when done with it.
    myConnection.Close()
End Sub 'ReadMyData
```

C# example:

```
public void ReadMyData(string myConnString) {
    string mySelectQuery = "SELECT OrderID, CustomerID FROM Orders";
    MySqlConnection myConnection = new MySqlConnection(myConnString);
    MySqlCommand myCommand = new MySqlCommand(mySelectQuery, myConnection);
    myConnection.Open();
    MySqlDataReader myReader;
    myReader = myCommand.ExecuteReader();
    // Always call Read before accessing data.
    while (myReader.Read()) {
        Console.WriteLine(myReader.GetInt32(0) + ", " + myReader.GetString(1));
    }
    // always call Close when done reading.
    myReader.Close();
    // Close the connection when done with it.
    myConnection.Close();
}
```

25.2.3.5.1. GetBytes

`GetBytes` returns the number of available bytes in the field. In most cases this is the exact length of the field. However, the number returned may be less than the true length of the field if `GetBytes` has already been used to obtain bytes from the field. This may be the case, for example, if the `MySqlDataReader` is reading a large data structure into a buffer. For more information, see the `SequentialAccess` setting for `MySqlCommand.CommandBehavior`.

If you pass a buffer that is a null reference (`Nothing` in Visual Basic), `GetBytes` returns the length of the field in bytes.

No conversions are performed; therefore the data retrieved must already be a byte array.

25.2.3.5.2. **GetTimeSpan**

Gets the value of the specified column as a [TimeSpan](#) object.

Parameters: The zero-based column ordinal.

Returns: The value of the specified column.

25.2.3.5.3. **GetDateTime**

Gets the value of the specified column as a [DateTime](#) object.

Note. MySql allows date columns to contain the value '0000-00-00' and datetime columns to contain the value '0000-00-00 00:00:00'. The [DateTime](#) structure cannot contain or represent these values. To read a datetime value from a column that might contain zero values, use [GetMySqlDateTime](#). The behavior of reading a zero datetime column using this method is defined by the [ZeroDateTimeBehavior](#) connection string option. For more information on this option, please refer to [MySqlConnection.ConnectionString](#).

Parameters: The zero-based column ordinal.

Returns: The value of the specified column.

25.2.3.5.4. **GetMySqlDateTime**

Gets the value of the specified column as a [MySql.Data.Types.MySqlDateTime](#) object.

Parameters: The zero-based column ordinal.

Returns: The value of the specified column.

25.2.3.5.5. **GetString**

Gets the value of the specified column as a [String](#) object.

Parameters: The zero-based column ordinal.

Returns: The value of the specified column.

25.2.3.5.6. **GetDecimal**

Gets the value of the specified column as a [Decimal](#) object.

Parameters: The zero-based column ordinal.

Returns: The value of the specified column.

25.2.3.5.7. **GetDouble**

Gets the value of the specified column as a double-precision floating point number.

Parameters: The zero-based column ordinal.

Returns: The value of the specified column.

25.2.3.5.8. GetFloat

Gets the value of the specified column as a single-precision floating point number.

Parameters: The zero-based column ordinal.

Returns: The value of the specified column.

25.2.3.5.9. GetGuid

Gets the value of the specified column as a globally-unique identifier (GUID).

Parameters: The zero-based column ordinal.

Returns: The value of the specified column.

25.2.3.5.10. GetInt16

Gets the value of the specified column as a 16-bit signed integer.

Parameters: The zero-based column ordinal.

Returns: The value of the specified column.

25.2.3.5.11. GetInt32

Gets the value of the specified column as a 32-bit signed integer.

Parameters: The zero-based column ordinal.

Returns: The value of the specified column.

25.2.3.5.12. GetInt64

Gets the value of the specified column as a 64-bit signed integer.

Parameters: The zero-based column ordinal.

Returns: The value of the specified column.

25.2.3.5.13. GetUInt16

Gets the value of the specified column as a 16-bit unsigned integer.

Parameters: The zero-based column ordinal.

Returns: The value of the specified column.

25.2.3.5.14. GetUInt32

Gets the value of the specified column as a 32-bit unsigned integer.

Parameters: The zero-based column ordinal.

Returns: The value of the specified column.

25.2.3.5.15. GetUInt64

Gets the value of the specified column as a 64-bit unsigned integer.

Parameters: The zero-based column ordinal.

Returns: The value of the specified column.

25.2.3.6. MySqlConnectionException

This class is created whenever the MySQL Data Provider encounters an error generated from the server.

Any open connections are not automatically closed when an exception is thrown. If the client application determines that the exception is fatal, it should close any open [MySQLDataReader](#) objects or [MySQLConnection](#) objects.

Examples

The following example generates a [MySQLException](#) due to a missing server, and then displays the exception.

Visual Basic example:

```
Public Sub ShowException()  
    Dim mySelectQuery As String = "SELECT column1 FROM table1"  
    Dim myConnection As New MySqlConnection ("Data Source=localhost;Database=Sample;")  
    Dim myCommand As New MySqlCommand(mySelectQuery, myConnection)  
    Try  
        myCommand.Connection.Open()  
    Catch e As MySqlConnectionException  
        MessageBox.Show( e.Message )  
    End Try  
End Sub
```

C# example:

```
public void ShowException()  
{  
    string mySelectQuery = "SELECT column1 FROM table1";  
    MySqlConnection myConnection =  
        new MySqlConnection("Data Source=localhost;Database=Sample;");  
    MySqlCommand myCommand = new MySqlCommand(mySelectQuery, myConnection);  
    try  
    {  
        myCommand.Connection.Open();  
    }  
    catch (MySqlConnectionException e)  
    {  
        MessageBox.Show( e.Message );  
    }  
}
```

25.2.3.7. MySqlParameter

Parameter names are not case sensitive.

Examples

The following example creates multiple instances of [MySqlParameter](#) through the [MySqlParameterCollection](#) collection within the [MySqlDataAdapter](#). These parameters are used to select data from the data source and place the data in the [DataSet](#). This example assumes that a [DataSet](#) and a [MySqlDataAdapter](#) have already been created with the appropriate schema, commands, and connection.

Visual Basic example:

```
Public Sub AddSqlParameter()
    ' ...
    ' create myDataSet and myDataAdapter
    ' ...
    myDataAdapter.SelectCommand.Parameters.Add("@CategoryName", MySqlDbType.VarChar, 80).Value = "toast"
    myDataAdapter.SelectCommand.Parameters.Add("@SerialNum", MySqlDbType.Long).Value = 239

    myDataAdapter.Fill(myDataSet)
End Sub 'AddSqlParameter
```

C# example:

```
public void AddSqlParameter()
{
    // ...
    // create myDataSet and myDataAdapter
    // ...
    myDataAdapter.SelectCommand.Parameters.Add("@CategoryName", MySqlDbType.VarChar, 80).Value = "toaster"
    myDataAdapter.SelectCommand.Parameters.Add("@SerialNum", MySqlDbType.Long).Value = 239;
    myDataAdapter.Fill(myDataSet);
}
```

25.2.3.8. MySqlConnection

The number of the parameters in the collection must be equal to the number of parameter placeholders within the command text, or an exception will be generated.

Examples

The following example creates multiple instances of [MySqlParameter](#) through the [MySqlParameterCollection](#) collection within the [MySqlConnection](#). These parameters are used to select data within the data source and place the data in the [DataSet](#). This code assumes that a [DataSet](#) and a [MySqlConnection](#) have already been created with the appropriate schema, commands, and connection.

Visual Basic example:

```
Public Sub AddParameters()
    ' ...
    ' create myDataSet and myDataAdapter
    ' ...
    myDataAdapter.SelectCommand.Parameters.Add("@CategoryName", MySqlDbType.VarChar, 80).Value = "toast"
    myDataAdapter.SelectCommand.Parameters.Add("@SerialNum", MySqlDbType.Long).Value = 239

    myDataAdapter.Fill(myDataSet)
End Sub 'AddSqlParameter
```

C# example:

```
public void AddSqlParameter()
{
    // ...
    // create myDataSet and myDataAdapter
    // ...
    myDataAdapter.SelectCommand.Parameters.Add("@CategoryName", MySqlDbType.VarChar, 80).Value = "toaster"
    myDataAdapter.SelectCommand.Parameters.Add("@SerialNum", MySqlDbType.Long).Value = 239;
    myDataAdapter.Fill(myDataSet);
}
```

25.2.3.9. MySqlTransaction

```

        myCommand.CommandText = "Insert into Region (RegionID, RegionDescription) VALUES (101, 'Description')";
        myCommand.ExecuteNonQuery();
        myTrans.Commit();
        Console.WriteLine("Both records are written to database.");
    }
    catch (Exception e)
    {
        try
        {
            myTrans.Rollback();
        }
        catch (MySqlException ex)
        {
            if (myTrans.Connection != null)
            {
                Console.WriteLine("An exception of type " + ex.GetType() +
                    " was encountered while attempting to roll back the transaction.");
            }
        }

        Console.WriteLine("An exception of type " + e.GetType() +
            " was encountered while inserting the data.");
        Console.WriteLine("Neither record was written to database.");
    }
    finally
    {
        myConnection.Close();
    }
}

```

25.2.3.9.1. Rollback

Rolls back a transaction from a pending state.

The Rollback method is equivalent to the MySQL statement ROLLBACK. The transaction can only be rolled back from a pending state (after BeginTransaction has been called, but before Commit is called).

Examples

The following example creates [MySqlConnection](#) and a [MySqlTransaction](#). It also demonstrates how to use the [MySqlConnection.BeginTransaction](#), [Commit](#), and [Rollback](#) methods.

Visual Basic example:

```

Public Sub RunSqlTransaction(myConnString As String)
    Dim myConnection As New MySqlConnection(myConnString)
    myConnection.Open()

    Dim myCommand As MySqlCommand = myConnection.CreateCommand()
    Dim myTrans As MySqlTransaction

    ' Start a local transaction
    myTrans = myConnection.BeginTransaction()

    ' Must assign both transaction object and connection
    ' to Command object for a pending local transaction
    myCommand.Connection = myConnection
    myCommand.Transaction = myTrans

    Try
        myCommand.CommandText = "Insert into mytable (id, desc) VALUES (100, 'Description')";
        myCommand.ExecuteNonQuery()
        myCommand.CommandText = "Insert into mytable (id, desc) VALUES (101, 'Description')";
        myCommand.ExecuteNonQuery()
        myTrans.Commit()
        Console.WriteLine("Success.")
    Catch e As Exception
        Try
            myTrans.Rollback()
        Catch ex As MySqlException
            If Not myTrans.Connection Is Nothing Then
                Console.WriteLine("An exception of type " & ex.GetType().ToString() & _

```

```

        " was encountered while attempting to roll back the transaction.")
    End If
End Try

Console.WriteLine("An exception of type " & e.GetType().ToString() & _
    "was encountered while inserting the data.")
Console.WriteLine("Neither record was written to database.")
Finally
    myConnection.Close()
End Try
End Sub

```

C# example:

```

public void RunSqlTransaction(string myConnString)
{
    MySqlConnection myConnection = new MySqlConnection(myConnString);
    myConnection.Open();
    MySqlCommand myCommand = myConnection.CreateCommand();
    MySqlTransaction myTrans;
    // Start a local transaction
    myTrans = myConnection.BeginTransaction();
    // Must assign both transaction object and connection
    // to Command object for a pending local transaction
    myCommand.Connection = myConnection;
    myCommand.Transaction = myTrans;
    try
    {
        myCommand.CommandText = "Insert into mytable (id, desc) VALUES (100, 'Description')";
        myCommand.ExecuteNonQuery();
        myCommand.CommandText = "Insert into mytable (id, desc) VALUES (101, 'Description')";
        myCommand.ExecuteNonQuery();
        myTrans.Commit();
        Console.WriteLine("Both records are written to database.");
    }
    catch (Exception e)
    {
        try
        {
            myTrans.Rollback();
        }
        catch (MySqlException ex)
        {
            if (myTrans.Connection != null)
            {
                Console.WriteLine("An exception of type " + ex.GetType() +
                    " was encountered while attempting to roll back the transaction.");
            }
        }

        Console.WriteLine("An exception of type " + e.GetType() +
            " was encountered while inserting the data.");
        Console.WriteLine("Neither record was written to database.");
    }
    finally
    {
        myConnection.Close();
    }
}

```

25.2.3.9.2. Commit

Commits the database transaction.

The `Commit` method is equivalent to the MySQL SQL statement `COMMIT`.

Examples

The following example creates `MySqlConnection` and a `MySqlTransaction`. It also demonstrates how to use the `MySqlConnection.BeginTransaction`, `Commit`, and `Rollback` methods.

Visual Basic example:

```

Public Sub RunSqlTransaction(myConnString As String)
    Dim myConnection As New MySqlConnection(myConnString)
    myConnection.Open()

    Dim myCommand As MySqlCommand = myConnection.CreateCommand()
    Dim myTrans As MySqlTransaction

    ' Start a local transaction
    myTrans = myConnection.BeginTransaction()

    ' Must assign both transaction object and connection
    ' to Command object for a pending local transaction
    myCommand.Connection = myConnection
    myCommand.Transaction = myTrans

    Try
        myCommand.CommandText = "Insert into mytable (id, desc) VALUES (100, 'Description')"
        myCommand.ExecuteNonQuery()
        myCommand.CommandText = "Insert into mytable (id, desc) VALUES (101, 'Description')"
        myCommand.ExecuteNonQuery()
        myTrans.Commit()
        Console.WriteLine("Success.")
    Catch e As Exception
        Try
            myTrans.Rollback()
        Catch ex As MySqlException
            If Not myTrans.Connection Is Nothing Then
                Console.WriteLine("An exception of type " & ex.GetType().ToString() & _
                    " was encountered while attempting to roll back the transaction.")
            End If
        End Try

        Console.WriteLine("An exception of type " & e.GetType().ToString() & _
            " was encountered while inserting the data.")
        Console.WriteLine("Neither record was written to database.")
    Finally
        myConnection.Close()
    End Try
End Sub

```

C# example:

```

public void RunSqlTransaction(string myConnString)
{
    MySqlConnection myConnection = new MySqlConnection(myConnString);
    myConnection.Open();
    MySqlCommand myCommand = myConnection.CreateCommand();
    MySqlTransaction myTrans;
    // Start a local transaction
    myTrans = myConnection.BeginTransaction();
    // Must assign both transaction object and connection
    // to Command object for a pending local transaction
    myCommand.Connection = myConnection;
    myCommand.Transaction = myTrans;
    try
    {
        myCommand.CommandText = "Insert into mytable (id, desc) VALUES (100, 'Description')";
        myCommand.ExecuteNonQuery();
        myCommand.CommandText = "Insert into mytable (id, desc) VALUES (101, 'Description')";
        myCommand.ExecuteNonQuery();
        myTrans.Commit();
        Console.WriteLine("Both records are written to database.");
    }
    catch(Exception e)
    {
        try
        {
            myTrans.Rollback();
        }
        catch (MySqlException ex)
        {
            if (myTrans.Connection != null)
            {
                Console.WriteLine("An exception of type " + ex.GetType() +
                    " was encountered while attempting to roll back the transaction.");
            }
        }
    }
}

```

```

    }
    Console.WriteLine("An exception of type " + e.GetType() +
        " was encountered while inserting the data.");
    Console.WriteLine("Neither record was written to database.");
}
finally
{
    myConnection.Close();
}
}

```

25.2.4. Connector/NET Reference

This section of the manual contains a complete reference to the Connector/NET ADO.NET component, automatically generated from the embedded documentation.

25.2.4.1. MySql.Data.MySqlClient

[Namespace hierarchy](#)

Classes

Class	Description
MySqlCommand	
MySqlCommandBuilder	
MySqlConnection	
MySqlDataAdapter	
MySqlDataReader	Provides a means of reading a forward-only stream of rows from a MySQL database. This class cannot be inherited.
MySqlError	Collection of error codes that can be returned by the server
MySqlException	The exception that is thrown when MySQL returns an error. This class cannot be inherited.
MySqlHelper	Helper class that makes it easier to work with the provider.
MySqlInfoMessageEventArgs	Provides data for the InfoMessage event. This class cannot be inherited.
MySqlParameter	Represents a parameter to a MySqlCommand , and optionally, its mapping to DataSet columns. This class cannot be inherited.
MySqlParameterCollection	Represents a collection of parameters relevant to a MySqlCommand as well as their respective mappings to columns in a DataSet. This class cannot be inherited.
MySqlRowUpdatedEventArgs	Provides data for the RowUpdated event. This class cannot be inherited.
MySqlRowUpdatingEventArgs	Provides data for the RowUpdating event. This class cannot be inherited.
MySqlTransaction	

Delegates

Delegate	Description
MySqlInfoMessageEventHandler	Represents the method that will handle the InfoMessage event of a MySqlConnection .
MySqlRowUpdatedEventHandler	Represents the method that will handle the RowUpdatedevent of a MySqlDataAdapter .
MySqlRowUpdatingEventHandler	Represents the method that will handle the RowUpdatingevent of a MySqlDataAdapter .

Enumerations

Enumeration	Description
MySqlDbType	Specifies MySQL specific data type of a field, property, for use in a MySqlParameter .
MySqlErrorCode

[MySqlCommand overview](#)

Public Instance Constructors

 MySqlCommand 	Overloaded. Initializes a new instance of the MySqlCommand class.
--------------------------------	---

Public Instance Properties

 CommandText 	
 CommandTimeout 	
 CommandType 	
 Connection 	
Container(inherited from Component)	Gets the IContainerthat contains the Component.
 IsPrepared 	
 Parameters 	
Site(inherited from Component)	Gets or sets the ISiteof the Component.
 Transaction 	
 UpdatedRowSource 	

Public Instance Methods

 Cancel 	Attempts to cancel the execution of a MySqlCommand. This operation is not supported.
CreateObjRef(inherited from MarshalByRefObject)	Creates an object that contains all the relevant information required to generate a proxy used to communicate with a remote object.
 CreateParameter 	Creates a new instance of a MySqlCommandParameter object.
Dispose(inherited from Component)	Releases all resources used by the Component.
Equals(inherited from Object)	Determines whether the specified Objectis equal to the current Object.
 ExecuteNonQuery 	
 ExecuteReader 	Overloaded.
 ExecuteScalar 	
GetHashCode(inherited from Object)	Serves as a hash function for a particular type. GetHashCodeis suitable for use in hashing algorithms and data structures like a hash table.
GetLifetimeService(inherited from MarshalByRefObject)	Retrieves the current lifetime service object that controls the lifetime policy for this instance.
GetType(inherited from Object)	Gets the Typeof the current instance.
InitializeLifetimeService(inherited from MarshalByRefObject)	Obtains a lifetime service object to control the lifetime policy for this instance.
 Prepare 	
ToString(inherited from Component)	Returns a Stringcontaining the name of the Component, if any. This method should not be overridden.

Public Instance Events

Disposed(inherited from Component)	Adds an event handler to listen to the Disposed event on the component.
------------------------------------	---

[MySQLConnection overview](#)**Public Instance Constructors**

MySQLConnection	Overloaded. Initializes a new instance of the MySQLConnection class.
---------------------------------	--

Public Instance Properties

ConnectionString	
ConnectionTimeout	
Container(inherited from Component)	Gets the IContainerthat contains the Component.
Database	
DataSource	Gets the name of the MySQL server to which to connect.
ServerThread	Returns the id of the server thread this connection is executing on
ServerVersion	
Site(inherited from Component)	Gets or sets the ISiteof the Component.
State	
UseCompression	Indicates if this connection should use compression when communicating with the server.

Public Instance Methods

BeginTransaction	Overloaded.
ChangeDatabase	
Close	
CreateCommand	
CreateObjRef(inherited from MarshalByRefObject)	Creates an object that contains all the relevant information required to generate a proxy used to communicate with a remote object.
Dispose(inherited from Component)	Releases all resources used by the Component.
Equals(inherited from Object)	Determines whether the specified Objectis equal to the current Object.
GetHashCode(inherited from Object)	Serves as a hash function for a particular type. GetHashCodeis suitable for use in hashing algorithms and data structures like a hash table.
GetLifetimeService(inherited from MarshalByRefObject)	Retrieves the current lifetime service object that controls the lifetime policy for this instance.
GetType(inherited from Object)	Gets the Typeof the current instance.
InitializeLifetimeService(inherited from MarshalByRefObject)	Obtains a lifetime service object to control the lifetime policy for this instance.
Open	
Ping	Ping
ToString(inherited from Component)	Returns a Stringcontaining the name of the Component, if any. This method should not be overrid-

	den.
--	------

Public Instance Events

Disposed(inherited from Component)	Adds an event handler to listen to the Dispose-event on the component.
InfoMessage	
StateChange

25.2.4.1.2.1.1.3.1.1.10.1.1. MySQLTransaction Class

For a list of all members of this type, see [MySQLTransaction Members](#) .

Syntax: Visual Basic

```
NotInheritable Public Class MySQLTransaction_
    Implements IDbTransaction, IDisposable
```

Syntax: C#

```
public sealed class MySQLTransaction : IDbTransaction, IDisposable
```

Thread Safety

Public static (Shared in Visual Basic) members of this type are safe for multithreaded operations. Instance members are not guaranteed to be thread-safe.

Requirements

Namespace: [MySQL.Data.MySqlClient](#)

Assembly: MySQL.Data (in MySQL.Data.dll)

See Also

[MySQLTransaction Members](#) , [MySQL.Data.MySqlClient Namespace](#)

25.2.4.1.2.1.1.3.1.1.10.1.1.1. MySQLTransaction Members

[MySQLTransaction overview](#)

Public Instance Properties

Connection	Gets the MySQLConnection object associated with the transaction, or a null reference (Nothing in Visual Basic) if the transaction is no longer valid.
IsolationLevel	Specifies the IsolationLevel for this transaction.

Public Instance Methods

Commit	
Equals(inherited from Object)	Determines whether the specified Object is equal to the current Object.
GetHashCode(inherited from Object)	Serves as a hash function for a particular type. GetHashCode is suitable for use in hashing algorithms and data structures like a hash table.
GetType(inherited from Object)	Gets the Type of the current instance.
Rollback	
ToString(inherited from Object)	Returns a String that represents the current Object.

[MySQLTransaction Class](#) , [MySQL.Data.MySqlClient Namespace](#)

25.2.4.1.2.1.1.3.1.1.10.1.1.1.1. Connection Property

Gets the [MySQLConnection](#) object associated with the transaction, or a null reference (Nothing in Visual Basic) if the transaction is no longer valid.

Syntax: Visual Basic

```
Public ReadOnly Property Connection As MySqlConnection
```

Syntax: C#

```
public MySqlConnection Connection {get;}
```

Property Value

The [MySQLConnection](#) object associated with this transaction.

Remarks

A single application may have multiple database connections, each with zero or more transactions. This property enables you to determine the connection object associated with a particular transaction created by [BeginTransaction](#) .

See Also

[MySQLTransaction Class](#) , [MySQL.Data.MySqlClient Namespace](#)

25.2.4.1.2.1.1.3.1.1.10.1.1.1.2. IsolationLevel Property

Specifies the IsolationLevel for this transaction.

Syntax: Visual Basic

```
NotOverridable Public ReadOnly Property IsolationLevel As IsolationLevel _  
- Implements IDbTransaction.IsolationLevel
```

Syntax: C#

```
public System.Data.IsolationLevel IsolationLevel {get;}
```

Property Value

The IsolationLevel for this transaction. The default is ReadCommitted.

Implements

IDbTransaction.IsolationLevel

Remarks

Parallel transactions are not supported. Therefore, the IsolationLevel applies to the entire transaction.

25.2.4.1.2.1.7.1. MySqlParameterCollection Class

Represents a collection of parameters relevant to a [MySQLCommand](#) as well as their respective mappings to columns in a DataSet. This class cannot be inherited.

For a list of all members of this type, see [MySQLParameterCollection Members](#) .

Syntax: Visual Basic

```
NotInheritable Public Class MySQLParameterCollection_
    Inherits MarshalByRefObject_
    Implements IDataParameterCollection, IList, ICollection, IEnumerable
```

Syntax: C#

```
public sealed class MySQLParameterCollection : MarshalByRefObject, IDataParameterCollection, IList, IC
```

Thread Safety

Public static (Shared in Visual Basic) members of this type are safe for multithreaded operations. Instance members are not guaranteed to be thread-safe.

Requirements

Namespace: [MySQL.Data.MySqlClient](#)

Assembly: MySQL.Data (in MySQL.Data.dll)

See Also

[MySQLParameterCollection Members](#) , [MySQL.Data.MySqlClient Namespace](#)

25.2.4.1.2.1.7.1.1. MySQLParameterCollection Members

[MySQLParameterCollection overview](#)

Public Instance Constructors

MySQLParameterCollection Constructor	Initializes a new instance of the MySQLParameterCollection class.
--	---

Public Instance Properties

Count	Gets the number of MySQLParameter objects in the collection.
Item	Overloaded. Gets the MySQLParameter with a specified attribute. In C#, this property is the indexer for the MySQLParameterCollection class.

Public Instance Methods

Add	Overloaded. Adds the specified MySQLParameter object to the MySQLParameterCollection .
Clear	Removes all items from the collection.
Contains	Overloaded. Gets a value indicating whether a MySQLParameter exists in the collection.
CopyTo	Copies MySQLParameter objects from the MySQLParameterCollection to the specified array.
CreateObjRef (inherited from MarshalByRefOb-	Creates an object that contains all the relevant in-

ject)	formation required to generate a proxy used to communicate with a remote object.
Equals(inherited from Object)	Determines whether the specified Object is equal to the current Object.
GetHashCode(inherited from Object)	Serves as a hash function for a particular type. GetHashCode is suitable for use in hashing algorithms and data structures like a hash table.
GetLifetimeService(inherited from MarshalByRefObject)	Retrieves the current lifetime service object that controls the lifetime policy for this instance.
GetType(inherited from Object)	Gets the Type of the current instance.
IndexOf	Overloaded. Gets the location of a MySQLParameter in the collection.
InitializeLifetimeService(inherited from MarshalByRefObject)	Obtains a lifetime service object to control the lifetime policy for this instance.
Insert	Inserts a MySQLParameter into the collection at the specified index.
Remove	Removes the specified MySQLParameter from the collection.
RemoveAt	Overloaded. Removes the specified MySQLParameter from the collection.
ToString(inherited from Object)	Returns a String that represents the current Object.

[MySQLParameterCollection Class](#) , [MySQL.Data.MySqlClient Namespace](#)

25.2.4.1.2.1.7.1.1.1. MySQLParameterCollection Constructor

Initializes a new instance of the [MySQLParameterCollection](#) class.

Syntax: Visual Basic

```
Public Sub New()
```

Syntax: C#

```
public MySQLParameterCollection();
```

See Also

[MySQLParameterCollection Class](#) , [MySQL.Data.MySqlClient Namespace](#)

25.2.4.1.2.1.7.1.1.2. Count Property

Gets the number of [MySQLParameter](#) objects in the collection.

Syntax: Visual Basic

```
NotOverridable Public ReadOnly Property Count As Integer _  
_ Implements ICollection.Count
```

Syntax: C#

```
public int Count {get;}
```

Implements

ICollection.Count

See Also

[MySQLParameterCollection Class](#) , [MySQL.Data.MySqlClient Namespace](#)

25.2.4.1.2.1.7.1.1.3. Item Property

Gets the [MySQLParameter](#) with a specified attribute. In C#, this property is the indexer for the [MySQLParameterCollection](#) class.

Overload List

Gets the [MySQLParameter](#) at the specified index.

- `public MySQLParameter this[int] {get; set;}`

Gets the [MySQLParameter](#) with the specified name.

- `public MySQLParameter this[string] {get; set;}`

See Also

[MySQLParameterCollection Class](#) , [MySQL.Data.MySqlClient Namespace](#)

25.2.4.1.2.1.7.1.1.3.1. MySQLParameter Class

Represents a parameter to a [MySQLCommand](#) , and optionally, its mapping to DataSetcolumns. This class cannot be inherited.

For a list of all members of this type, see [MySQLParameter Members](#) .

Syntax: Visual Basic

```
NotInheritable Public Class MySQLParameter_
    Inherits MarshalByRefObject_
    Implements IDataParameter, IDbDataParameter, ICloneable
```

Syntax: C#

```
public sealed class MySQLParameter : MarshalByRefObject, IDataParameter, IDbDataParameter, ICloneable
```

Thread Safety

Public static (Shared in Visual Basic) members of this type are safe for multithreaded operations. Instance members are not guaranteed to be thread-safe.

Requirements

Namespace: [MySQL.Data.MySqlClient](#)

Assembly: MySql.Data (in MySql.Data.dll)

25.2.4.1.2.1.7.1.1.3.1.1. MySqlConnection Members

[MySqlParameter overview](#)

Public Instance Constructors

MySqlParameter	Overloaded. Initializes a new instance of the MySqlConnection class.
--------------------------------	--

Public Instance Properties

DbType	Gets or sets the DbType of the parameter.
Direction	Gets or sets a value indicating whether the parameter is input-only, output-only, bidirectional, or a stored procedure return value parameter. As of MySql version 4.1 and earlier, input-only is the only valid choice.
IsNullable	Gets or sets a value indicating whether the parameter accepts null values.
IsUnsigned	
MySqlDbType	Gets or sets the MySqlDbType of the parameter.
ParameterName	Gets or sets the name of the MySqlConnection.
Precision	Gets or sets the maximum number of digits used to represent the Value property.
Scale	Gets or sets the number of decimal places to which Value is resolved.
Size	Gets or sets the maximum size, in bytes, of the data within the column.
SourceColumn	Gets or sets the name of the source column that is mapped to the DataSet and used for loading or returning the Value .
SourceVersion	Gets or sets the DataRowVersion to use when loading Value .
Value	Gets or sets the value of the parameter.

Public Instance Methods

CreateObjRef (inherited from MarshalByRefObject)	Creates an object that contains all the relevant information required to generate a proxy used to communicate with a remote object.
Equals (inherited from Object)	Determines whether the specified Object is equal to the current Object.
GetHashCode (inherited from Object)	Serves as a hash function for a particular type. GetHashCode is suitable for use in hashing algorithms and data structures like a hash table.

GetLifetimeService(inherited from MarshalByRefObject)	Retrieves the current lifetime service object that controls the lifetime policy for this instance.
GetType(inherited from Object)	Gets the Type of the current instance.
InitializeLifetimeService(inherited from MarshalByRefObject)	Obtains a lifetime service object to control the lifetime policy for this instance.
ToString	Overridden. Gets a string containing the ParameterName .

25.2.4.1.2.1.7.1.1.3.1.1.1. MySQLParameter Constructor

Initializes a new instance of the MySQLParameter class.

Overload List

Initializes a new instance of the MySQLParameter class.

- [public MySQLParameter\(\);](#)

Initializes a new instance of the [MySQLParameter](#) class with the parameter name and the data type.

- [public MySQLParameter\(string,MySQLDbType\);](#)

Initializes a new instance of the [MySQLParameter](#) class with the parameter name, the [MySQLDbType](#) , and the size.

- [public MySQLParameter\(string,MySQLDbType,int\);](#)

Initializes a new instance of the [MySQLParameter](#) class with the parameter name, the type of the parameter, the size of the parameter, a [ParameterDirection](#), the precision of the parameter, the scale of the parameter, the source column, a [DataRowVersion](#) to use, and the value of the parameter.

- [public MySQLParameter\(string,MySQLDbType,int,ParameterDirection,bool,byte,byte,string,DataRowVersion,object\);](#)

Initializes a new instance of the [MySQLParameter](#) class with the parameter name, the [MySQLDbType](#) , the size, and the source column name.

- [public MySQLParameter\(string,MySQLDbType,int,string\);](#)

Initializes a new instance of the [MySQLParameter](#) class with the parameter name and a value of the new MySQLParameter.

```
Public Enum MySqlDbType
```

Syntax: C#

```
public enum MySqlDbType
```

Members

Member Name	Description
VarChar	A variable-length string containing 0 to 65535 characters
Timestamp	A timestamp. The range is '1970-01-01 00:00:00' to sometime in the year 2037
LongBlob	A BLOB or TEXT column with a maximum length of 4294967295 or 4G (2 ³² - 1) characters
Time	Time The range is '-838:59:59' to '838:59:59'.
TinyBlob	A BLOB or TEXT column with a maximum length of 255 (2 ⁸ - 1) characters
Datetime	DateTime The supported range is '1000-01-01 00:00:00' to '9999-12-31 23:59:59'.
Decimal	Decimal A fixed precision and scale numeric value between -1038 -1 and 10 38 -1.
UByte	
Blob	A BLOB or TEXT column with a maximum length of 65535 (2 ¹⁶ - 1) characters
Double	Double A normal-size (double-precision) floating-point number. Allowable values are - 1.7976931348623157E+308 to - 2.2250738585072014E-308, 0, and 2.2250738585072014E-308 to 1.7976931348623157E+308.
Newdate	Obsolete Use Datetime or Date type
Byte	Byte The signed range is -128 to 127. The unsigned range is 0 to 255.
Date	Date The supported range is '1000-01-01' to '9999-12-31'.
VarChar	A variable-length string containing 0 to 255 characters
UInt16	
UInt24	
Int16	Int16 A 16-bit signed integer. The signed range is -

	32768 to 32767. The unsigned range is 0 to 65535
NewDecimal	New Decimal
Set	A set. A string object that can have zero or more values, each of which must be chosen from the list of values 'value1', 'value2', ... A SET can have a maximum of 64 members.
String	Obsolete Use VarChar type
Enum	An enumeration. A string object that can have only one value, chosen from the list of values 'value1', 'value2', ..., NULL or the special "" error value. An ENUM can have a maximum of 65535 distinct values
Geometry	
UInt64	
Int64	Int64 A 64-bit signed integer.
UInt32	
Int24	Specifies a 24 (3 byte) signed or unsigned value.
Bit	Bit-field data type
Float	Single A small (single-precision) floating-point number. Allowable values are -3.402823466E+38 to -1.175494351E-38, 0, and 1.175494351E-38 to 3.402823466E+38.
Year	A year in 2- or 4-digit format (default is 4-digit). The allowable values are 1901 to 2155, 0000 in the 4-digit year format, and 1970-2069 if you use the 2-digit format (70-69)
Int32	Int32 A 32-bit signed integer
MediumBlob	A BLOB or TEXT column with a maximum length of 16777215 (2 ²⁴ - 1) characters

Requirements

Namespace: [MySql.Data.MySqlClient](#)

Assembly: MySql.Data (in MySql.Data.dll)

See Also

[MySql.Data.MySqlClient Namespace](#)

25.2.4.1.2.1.7.1.1.3.1.1.3. MySqlParameter Constructor (String, MySqlDbType, Int32)

Initializes a new instance of the [MySqlParameter](#) class with the parameter name, the [MySqlDbType](#), and the size.

Syntax: Visual Basic

```
Overloads Public Sub New( _
    ByVal parameterName As String, _
    ByVal dbType As MySqlDbType, _
    ByVal size As Integer _
)
```

Syntax: C#

```
public MySqlParameter(
    stringparameterName,
    MySqlDbTypedbType,
    intsize
);
```

Parameters

- `parameterName`: The name of the parameter to map.
- `dbType`: One of the [MySqlDbType](#) values.
- `size`: The length of the parameter.

See Also

[MySqlParameter Class](#) , [MySql.Data.MySqlClient Namespace](#) , [MySqlParameter Constructor Overload List](#)

25.2.4.1.2.1.7.1.1.3.1.1.1.4. MySqlParameter Constructor (String, MySqlDbType, Int32, ParameterDirection, Boolean, Byte, Byte, String, DataRowVersion, Object)

Initializes a new instance of the [MySqlParameter](#) class with the parameter name, the type of the parameter, the size of the parameter, a [ParameterDirection](#), the precision of the parameter, the scale of the parameter, the source column, a [DataRowVersion](#) to use, and the value of the parameter.

Syntax: Visual Basic

```
Overloads Public Sub New( _
    ByVal parameterName As String, _
    ByVal dbType As MySqlDbType, _
    ByVal size As Integer, _
    ByVal direction As ParameterDirection, _
    ByVal isNullable As Boolean, _
    ByVal precision As Byte, _
    ByVal scale As Byte, _
    ByVal sourceColumn As String, _
    ByVal sourceVersion As DataRowVersion, _
    ByVal value As Object _
)
```

Syntax: C#

```
public MySqlParameter(
    stringparameterName,
    MySqlDbTypedbType,
    intsize,
    ParameterDirectiondirection,
    boolisNullable,
    byteprecision,
    bytescale,
    stringsourceColumn,
    DataRowVersionsourceVersion,
    objectvalue
);
```

```
);
```

Parameters

- `parameterName`: The name of the parameter to map.
- `dbType`: One of the [MySQLDbType](#) values.
- `size`: The length of the parameter.
- `direction`: One of the [ParameterDirection](#) values.
- `isNullable`: true if the value of the field can be null, otherwise false.
- `precision`: The total number of digits to the left and right of the decimal point to which [Value](#) is resolved.
- `scale`: The total number of decimal places to which [Value](#) is resolved.
- `sourceColumn`: The name of the source column.
- `sourceVersion`: One of the [DataRowVersion](#) values.
- `value`: An Object that is the value of the [MySQLParameter](#).

Exceptions

Exception Type	Condition
ArgumentException

25.2.4.1.2.1.7.1.1.3.1.1.4.1. Value Property

Gets or sets the value of the parameter.

Syntax: Visual Basic

```
NotOverridable Public Property Value As Object _
    Implements IDataParameter.Value
```

Syntax: C#

```
public object Value {get; set;}
```

Implements

[IDataParameter.Value](#)

See Also

[MySQLParameter Class](#) , [MySQL.Data.MySqlClient Namespace](#)

25.2.4.1.2.1.7.1.1.3.1.1.1.5. MySQLParameter Constructor (String, MySqlDbType, Int32, String)

Initializes a new instance of the [MySQLParameter](#) class with the parameter name, the [MySqlDbType](#) , the size, and the source column name.

Syntax: Visual Basic

```
Overloads Public Sub New( _
    ByVal parameterName As String, _
    ByVal dbType As MySqlDbType, _
    ByVal size As Integer, _
    ByVal sourceColumn As String _
)
```

Syntax: C#

```
public MySQLParameter(
    stringparameterName,
    MySqlDbTypedbType,
    intsize,
    stringsourceColumn
);
```

Parameters

- [parameterName](#): The name of the parameter to map.
- [dbType](#): One of the [MySqlDbType](#) values.
- [size](#): The length of the parameter.
- [sourceColumn](#): The name of the source column.

25.2.4.1.2.1.7.1.1.3.1.1.1.6. MySQLParameter Constructor (String, Object)

Initializes a new instance of the [MySQLParameter](#) class with the parameter name and a value of the new [MySQLParameter](#).

Syntax: Visual Basic

```
Overloads Public Sub New( _
    ByVal parameterName As String, _
    ByVal value As Object _
)
```

Syntax: C#

```
public MySQLParameter(
    stringparameterName,
    objectvalue
);
```

Parameters

- `parameterName`: The name of the parameter to map.
- `value`: An Object that is the value of the [MySQLParameter](#) .

See Also

[MySQLParameter Class](#) , [MySQL.Data.MySqlClient Namespace](#) , [MySQLParameter Constructor Overload List](#)

25.2.4.1.2.1.7.1.1.3.1.1.2. DbType Property

Gets or sets the DbType of the parameter.

Syntax: Visual Basic

```
NotOverridable Public Property DbType As DbType _  
    Implements IDataParameter.DbType
```

Syntax: C#

```
public System.Data.DbType DbType {get; set;}
```

Implements

IDataParameter.DbType

See Also

[MySQLParameter Class](#) , [MySQL.Data.MySqlClient Namespace](#)

25.2.4.1.2.1.7.1.1.3.1.1.3. Direction Property

Gets or sets a value indicating whether the parameter is input-only, output-only, bidirectional, or a stored procedure return value parameter. As of MySQL version 4.1 and earlier, input-only is the only valid choice.

Syntax: Visual Basic

```
NotOverridable Public Property Direction As ParameterDirection _  
    Implements IDataParameter.Direction
```

Syntax: C#

```
public System.Data.ParameterDirection Direction {get; set;}
```

Implements

IDataParameter.Direction

See Also

[MySQLParameter Class](#) , [MySQL.Data.MySqlClient Namespace](#)

25.2.4.1.2.1.7.1.1.3.1.1.4. IsNullable Property

Gets or sets a value indicating whether the parameter accepts null values.

Syntax: Visual Basic

```
NotOverridable Public Property IsNullable As Boolean _  
    Implements IDataParameter.IsNullable
```

Syntax: C#

```
public bool IsNullable {get; set;}
```

Implements

IDataParameter.IsNullable

See Also

[MySQLParameter Class](#) , [MySQL.Data.MySqlClient Namespace](#)

25.2.4.1.2.1.7.1.1.3.1.1.5. IsUnsigned Property

Syntax: Visual Basic

```
Public Property IsUnsigned As Boolean
```

Syntax: C#

```
public bool IsUnsigned {get; set;}
```

See Also

[MySQLParameter Class](#) , [MySQL.Data.MySqlClient Namespace](#)

25.2.4.1.2.1.7.1.1.3.1.1.6. MySQLDbType Property

Gets or sets the MySQLDbType of the parameter.

Syntax: Visual Basic

```
Public Property MySQLDbType As MySQLDbType
```

Syntax: C#

```
public MySQLDbType MySQLDbType {get; set;}
```

See Also

[MySQLParameter Class](#) , [MySQL.Data.MySqlClient Namespace](#)

25.2.4.1.2.1.7.1.1.3.1.1.7. ParameterName Property

Gets or sets the name of the MySQLParameter.

Syntax: Visual Basic

```
NotOverridable Public Property ParameterName As String _  
    Implements IDataParameter.ParameterName
```

Syntax: C#

```
public string ParameterName {get; set;}
```

Implements

IDataParameter.ParameterName

See Also

[MySQLParameter Class](#) , [MySQL.Data.MySqlClient Namespace](#)

25.2.4.1.2.1.7.1.1.3.1.1.8. Precision Property

Gets or sets the maximum number of digits used to represent the [Value](#) property.

Syntax: Visual Basic

```
NotOverridable Public Property Precision As Byte _  
- Implements IDbDataParameter.Precision
```

Syntax: C#

```
public byte Precision {get; set;}
```

Implements

IDbDataParameter.Precision

See Also

[MySQLParameter Class](#) , [MySQL.Data.MySqlClient Namespace](#)

25.2.4.1.2.1.7.1.1.3.1.1.9. Scale Property

Gets or sets the number of decimal places to which [Value](#) is resolved.

Syntax: Visual Basic

```
NotOverridable Public Property Scale As Byte _  
- Implements IDbDataParameter.Scale
```

Syntax: C#

```
public byte Scale {get; set;}
```

Implements

IDbDataParameter.Scale

See Also

[MySQLParameter Class](#) , [MySQL.Data.MySqlClient Namespace](#)

25.2.4.1.2.1.7.1.1.3.1.1.10. Size Property

Gets or sets the maximum size, in bytes, of the data within the column.

Syntax: Visual Basic

```
NotOverridable Public Property Size As Integer _  
    Implements IDbDataParameter.Size
```

Syntax: C#

```
public int Size {get; set;}
```

Implements

IDbDataParameter.Size

See Also

[MySQLParameter Class](#) , [MySQL.Data.MySqlClient Namespace](#)

25.2.4.1.2.1.7.1.1.3.1.1.11. SourceColumn Property

Gets or sets the name of the source column that is mapped to the DataSet and used for loading or returning the [Value](#) .

Syntax: Visual Basic

```
NotOverridable Public Property SourceColumn As String _  
    Implements IDataParameter.SourceColumn
```

Syntax: C#

```
public string SourceColumn {get; set;}
```

Implements

IDataParameter.SourceColumn

See Also

[MySQLParameter Class](#) , [MySQL.Data.MySqlClient Namespace](#)

25.2.4.1.2.1.7.1.1.3.1.1.12. SourceVersion Property

Gets or sets the DataRowVersion to use when loading [Value](#) .

Syntax: Visual Basic

```
NotOverridable Public Property SourceVersion As DataRowVersion _  
    Implements IDataParameter.SourceVersion
```

Syntax: C#

```
public System.Data.DataRowVersion SourceVersion {get; set;}
```

Implements

IDataParameter.SourceVersion

See Also

[MySQLParameter Class](#) , [MySQL.Data.MySqlClient Namespace](#)

25.2.4.1.2.1.7.1.1.3.1.1.13. MySQLParameter.ToString Method

Overridden. Gets a string containing the [ParameterName](#) .

Syntax: Visual Basic

```
Overrides Public Function ToString() As String
```

Syntax: C#

```
public override string ToString();
```

Return Value**See Also**

[MySQLParameter Class](#) , [MySQL.Data.MySqlClient Namespace](#)

25.2.4.1.2.1.7.1.1.3.2. Item Property (Int32)

Gets the [MySQLParameter](#) at the specified index.

Syntax: Visual Basic

```
Overloads Public Default Property Item( _  
    ByVal index As Integer _  
) As MySQLParameter
```

Syntax: C#

```
public MySQLParameter this[  
    int index  
] {get; set;}
```

See Also

[MySQLParameterCollection Class](#) , [MySQL.Data.MySqlClient Namespace](#) , [MySQLParameterCollection.Item Overload List](#)

25.2.4.1.2.1.7.1.1.3.3. Item Property (String)

Gets the [MySQLParameter](#) with the specified name.

Syntax: Visual Basic

```
Overloads Public Default Property Item( _  
    ByVal name As String _  
) As MySQLParameter
```

Syntax: C#

```
public MySQLParameter this[  
    string name  
] {get; set;}
```

See Also

[MySQLParameterCollection Class](#) , [MySQL.Data.MySqlClient Namespace](#) , [MySQLParameterCollection.Item Overload List](#)

25.2.4.1.2.1.7.1.1.4. Add Method

Adds the specified [MySQLParameter](#) object to the [MySQLParameterCollection](#) .

Overload List

Adds the specified [MySQLParameter](#) object to the [MySQLParameterCollection](#) .

- `public MySQLParameter Add(MySQLParameter);`

Adds the specified [MySQLParameter](#) object to the [MySQLParameterCollection](#) .

- `public int Add(object);`

Adds a [MySQLParameter](#) to the [MySQLParameterCollection](#) given the parameter name and the data type.

- `public MySQLParameter Add(string,MySQLDbType);`

Adds a [MySQLParameter](#) to the [MySQLParameterCollection](#) with the parameter name, the data type, and the column length.

- `public MySQLParameter Add(string,MySQLDbType,int);`

Adds a [MySQLParameter](#) to the [MySQLParameterCollection](#) with the parameter name, the data type, the column length, and the source column name.

- `public MySQLParameter Add(string,MySQLDbType,int,string);`

Adds a [MySQLParameter](#) to the [MySQLParameterCollection](#) given the specified parameter name and value.

- `public MySQLParameter Add(string,object);`

See Also

[MySQLParameterCollection Class](#) , [MySQL.Data.MySqlClient Namespace](#)

25.2.4.1.2.1.7.1.1.4.1. MySQLParameterCollection.Add Method (MySQLParameter)

Adds the specified [MySQLParameter](#) object to the [MySQLParameterCollection](#) .

Syntax: Visual Basic

```
Overloads Public Function Add( _
```

```
ByVal value As MySqlParameter _  
) As MySqlParameter
```

Syntax: C#

```
public MySqlParameter Add(  
    MySqlParameter value  
);
```

Parameters

- `value`: The [MySqlParameter](#) to add to the collection.

Return Value

The newly added [MySqlParameter](#) object.

See Also

[MySqlParameterCollection Class](#) , [MySql.Data.MySqlClient Namespace](#) , [MySqlParameterCollection.Add Overload List](#)

25.2.4.1.2.1.7.1.1.4.2. MySqlConnection.Add Method (Object)

Adds the specified [MySqlParameter](#) object to the [MySqlParameterCollection](#) .

Syntax: Visual Basic

```
NotOverridable Overloads Public Function Add( _  
    ByVal value As Object _  
    ) As Integer _  
    Implements IList.Add
```

Syntax: C#

```
public int Add(  
    object value  
);
```

Parameters

- `value`: The [MySqlParameter](#) to add to the collection.

Return Value

The index of the new [MySqlParameter](#) object.

Implements

[IList.Add](#)

See Also

[MySqlParameterCollection Class](#) , [MySql.Data.MySqlClient Namespace](#) , [MySqlParameterCollection.Add Overload List](#)

25.2.4.1.2.1.7.1.1.4.3. MySqlConnection.Add Method (String, MySqlDbType)

Adds a [MySqlParameter](#) to the [MySqlParameterCollection](#) given the parameter name and the data type.

Syntax: Visual Basic

```
Overloads Public Function Add( _  
    ByVal parameterName As String, _  
    ByVal dbType As MySqlDbType _  
) As MySqlParameter
```

Syntax: C#

```
public MySqlParameter Add(  
    stringparameterName,  
    MySqlDbTypedbType  
);
```

Parameters

- [parameterName](#): The name of the parameter.
- [dbType](#): One of the [MySqlDbType](#) values.

Return Value

The newly added [MySqlParameter](#) object.

See Also

[MySqlParameterCollection Class](#) , [MySql.Data.MySqlClient Namespace](#) , [MySqlParameterCollection.Add Overload List](#)

25.2.4.1.2.1.7.1.1.4.4. MySqlConnection.Add Method (String, MySqlDbType, Int32)

Adds a [MySqlParameter](#) to the [MySqlParameterCollection](#) with the parameter name, the data type, and the column length.

Syntax: Visual Basic

```
Overloads Public Function Add( _  
    ByVal parameterName As String, _  
    ByVal dbType As MySqlDbType, _  
    ByVal size As Integer _  
) As MySqlParameter
```

Syntax: C#

```
public MySqlParameter Add(  
    stringparameterName,  
    MySqlDbTypedbType,  
    intsize  
);
```

Parameters

- [parameterName](#): The name of the parameter.
- [dbType](#): One of the [MySqlDbType](#) values.

- `size`: The length of the column.

Return Value

The newly added [MySQLParameter](#) object.

See Also

[MySQLParameterCollection Class](#) , [MySQL.Data.MySqlClient Namespace](#) , [MySQLParameterCollection.Add Overload List](#)

25.2.4.1.2.1.7.1.1.4.5. MySQLParameterCollection.Add Method (String, MySqlDbType, Int32, String)

Adds a [MySQLParameter](#) to the [MySQLParameterCollection](#) with the parameter name, the data type, the column length, and the source column name.

Syntax: Visual Basic

```
Overloads Public Function Add( _  
    ByVal parameterName As String, _  
    ByVal dbType As MySqlDbType, _  
    ByVal size As Integer, _  
    ByVal sourceColumn As String _  
) As MySQLParameter
```

Syntax: C#

```
public MySQLParameter Add(  
    stringparameterName,  
    MySqlDbTypedbType,  
    intsize,  
    stringsourceColumn  
);
```

Parameters

- `parameterName`: The name of the parameter.
- `dbType`: One of the [MySQLDbType](#) values.
- `size`: The length of the column.
- `sourceColumn`: The name of the source column.

Return Value

The newly added [MySQLParameter](#) object.

See Also

[MySQLParameterCollection Class](#) , [MySQL.Data.MySqlClient Namespace](#) , [MySQLParameterCollection.Add Overload List](#)

25.2.4.1.2.1.7.1.1.4.6. MySQLParameterCollection.Add Method (String, Object)

Adds a [MySQLParameter](#) to the [MySQLParameterCollection](#) given the specified parameter name and value.

Syntax: Visual Basic

```
Overloads Public Function Add( _  
    ByVal parameterName As String, _  
    ByVal value As Object _  
) As MySqlParameter
```

Syntax: C#

```
public MySqlParameter Add(  
    stringparameterName,  
    objectvalue  
);
```

Parameters

- `parameterName`: The name of the parameter.
- `value`: The [Value](#) of the [MySqlParameter](#) to add to the collection.

Return Value

The newly added [MySqlParameter](#) object.

See Also

[MySqlParameterCollection Class](#) , [MySql.Data.MySqlClient Namespace](#) , [MySqlParameterCollection.Add Overload List](#)

25.2.4.1.2.1.7.1.1.5. MySqlConnection.Clear Method

Removes all items from the collection.

Syntax: Visual Basic

```
NotOverridable Public Sub Clear() _  
    Implements IList.Clear
```

Syntax: C#

```
public void Clear();
```

Implements

[IList.Clear](#)

See Also

[MySqlParameterCollection Class](#) , [MySql.Data.MySqlClient Namespace](#)

25.2.4.1.2.1.7.1.1.6. Contains Method

Gets a value indicating whether a [MySqlParameter](#) exists in the collection.

Overload List

Gets a value indicating whether a [MySqlParameter](#) exists in the collection.

- `public bool Contains(object);`

Gets a value indicating whether a [MySQLParameter](#) with the specified parameter name exists in the collection.

- `public bool Contains(string);`

See Also

[MySQLParameterCollection Class](#) , [MySQL.Data.MySqlClient Namespace](#)

25.2.4.1.2.1.7.1.1.6.1. MySQLParameterCollection.Contains Method (Object)

Gets a value indicating whether a [MySQLParameter](#) exists in the collection.

Syntax: Visual Basic

```
NotOverridable Overloads Public Function Contains( _  
    ByVal value As Object _  
) As Boolean _  
— Implements IList.Contains
```

Syntax: C#

```
public bool Contains(  
    objectvalue  
);
```

Parameters

- `value`: The value of the [MySQLParameter](#) object to find.

Return Value

true if the collection contains the [MySQLParameter](#) object; otherwise, false.

Implements

[IList.Contains](#)

See Also

[MySQLParameterCollection Class](#) , [MySQL.Data.MySqlClient Namespace](#) , [MySQLParameterCollection.Contains Overload List](#)

25.2.4.1.2.1.7.1.1.6.2. MySQLParameterCollection.Contains Method (String)

Gets a value indicating whether a [MySQLParameter](#) with the specified parameter name exists in the collection.

Syntax: Visual Basic

```
NotOverridable Overloads Public Function Contains( _  
    ByVal name As String _  
) As Boolean _  
—
```

```
Implements IDataParameterCollection.Contains
```

Syntax: C#

```
public bool Contains(  
    stringname  
);
```

Parameters

- `name`: The name of the [MySQLParameter](#) object to find.

Return Value

true if the collection contains the parameter; otherwise, false.

Implements

[IDataParameterCollection.Contains](#)

See Also

[MySQLParameterCollection Class](#) , [MySQL.Data.MySqlClient Namespace](#) , [MySQLParameterCollection.Contains Overload List](#)

25.2.4.1.2.1.7.1.1.7. MySQLParameterCollection.CopyTo Method

Copies MySQLParameter objects from the MySQLParameterCollection to the specified array.

Syntax: Visual Basic

```
NotOverridable Public Sub CopyTo( _  
    ByVal array As Array, _  
    ByVal index As Integer _  
) _  
- Implements ICollection.CopyTo
```

Syntax: C#

```
public void CopyTo(  
    Arrayarray,  
    intindex  
);
```

Parameters

- `array`:
- `index`:

Implements

[ICollection.CopyTo](#)

See Also

[MySQLParameterCollection Class](#) , [MySQL.Data.MySqlClient Namespace](#)

25.2.4.1.2.1.7.1.1.8. IndexOf Method

Gets the location of a [MySQLParameter](#) in the collection.

Overload List

Gets the location of a [MySQLParameter](#) in the collection.

- `public int IndexOf(object);`

Gets the location of the [MySQLParameter](#) in the collection with a specific parameter name.

- `public int IndexOf(string);`

See Also

[MySQLParameterCollection Class](#) , [MySQL.Data.MySqlClient Namespace](#)

25.2.4.1.2.1.7.1.1.8.1. MySQLParameterCollection.IndexOf Method (Object)

Gets the location of a [MySQLParameter](#) in the collection.

Syntax: Visual Basic

```
NotOverridable Overloads Public Function IndexOf( _  
    ByVal value As Object _  
) As Integer _  
- Implements IList.IndexOf
```

Syntax: C#

```
public int IndexOf(  
    objectvalue  
);
```

Parameters

- `value`: The [MySQLParameter](#) object to locate.

Return Value

The zero-based location of the [MySQLParameter](#) in the collection.

Implements

`IList.IndexOf`

See Also

[MySQLParameterCollection Class](#) , [MySQL.Data.MySqlClient Namespace](#) , [MySQLParameterCollection.IndexOf Overload List](#)

25.2.4.1.2.1.7.1.1.8.2. MySqlConnection.IndexOf Method (String)

Gets the location of the [MySqlParameter](#) in the collection with a specific parameter name.

Syntax: Visual Basic

```
NotOverridable Overloads Public Function IndexOf( _  
    ByVal parameterName As String _  
) As Integer _  
- Implements IDataParameterCollection.IndexOf
```

Syntax: C#

```
public int IndexOf(  
stringparameterName  
);
```

Parameters

- `parameterName`: The name of the [MySqlParameter](#) object to retrieve.

Return Value

The zero-based location of the [MySqlParameter](#) in the collection.

Implements

[IDataParameterCollection.IndexOf](#)

See Also

[MySqlParameterCollection Class](#) , [MySql.Data.MySqlClient Namespace](#) , [MySqlParameterCollection.IndexOf Overload List](#)

25.2.4.1.2.1.7.1.1.9. MySqlConnection.Insert Method

Inserts a [MySqlParameter](#) into the collection at the specified index.

Syntax: Visual Basic

```
NotOverridable Public Sub Insert( _  
    ByVal index As Integer, _  
    ByVal value As Object _  
) _  
- Implements IList.Insert
```

Syntax: C#

```
public void Insert(  
intindex,  
objectvalue  
);
```

Parameters

- `index`:

- `value`:

Implements

`IList.Insert`

See Also

[MySQLParameterCollection Class](#) , [MySQL.Data.MySqlClient Namespace](#)

25.2.4.1.2.1.7.1.1.10. MySQLParameterCollection.Remove Method

Removes the specified `MySQLParameter` from the collection.

Syntax: Visual Basic

```
NotOverridable Public Sub Remove( _  
    ByVal value As Object _  
) _  
- Implements IList.Remove
```

Syntax: C#

```
public void Remove(  
    objectvalue  
);
```

Parameters

- `value`:

Implements

`IList.Remove`

See Also

[MySQLParameterCollection Class](#) , [MySQL.Data.MySqlClient Namespace](#)

25.2.4.1.2.1.7.1.1.11. RemoveAt Method

Removes the specified `MySQLParameter` from the collection.

Overload List

Removes the specified `MySQLParameter` from the collection using a specific index.

- `public void RemoveAt(int);`

Removes the specified `MySQLParameter` from the collection using the parameter name.

- `public void RemoveAt(string);`

See Also

[MySQLParameterCollection Class](#) , [MySQL.Data.MySqlClient Namespace](#)

25.2.4.1.2.1.7.1.1.11.1. MySQLParameterCollection.RemoveAt Method (Int32)

Removes the specified [MySQLParameter](#) from the collection using a specific index.

Syntax: Visual Basic

```
NotOverridable Overloads Public Sub RemoveAt( _  
    ByVal index As Integer _  
) _  
- Implements IList.RemoveAt
```

Syntax: C#

```
public void RemoveAt(  
    int index  
);
```

Parameters

- [index](#): The zero-based index of the parameter.

Implements

IList.RemoveAt

See Also

[MySQLParameterCollection Class](#) , [MySQL.Data.MySqlClient Namespace](#) , [MySQLParameterCollection.RemoveAt Overload List](#)

25.2.4.1.2.1.7.1.1.11.2. MySQLParameterCollection.RemoveAt Method (String)

Removes the specified [MySQLParameter](#) from the collection using the parameter name.

Syntax: Visual Basic

```
NotOverridable Overloads Public Sub RemoveAt( _  
    ByVal name As String _  
) _  
- Implements IDataParameterCollection.RemoveAt
```

Syntax: C#

```
public void RemoveAt(  
    string name  
);
```

Parameters

- [name](#): The name of the [MySQLParameter](#) object to retrieve.

Implements

[IDataParameterCollection.RemoveAt](#)

See Also

[MySQLParameterCollection Class](#) , [MySQL.Data.MySqlClient Namespace](#) , [MySQLParameterCollection.RemoveAt Overload List](#)

25.2.4.1.2.1.8. Transaction Property

Syntax: Visual Basic

```
Public Property Transaction As MySQLTransaction
```

Syntax: C#

```
public MySQLTransaction Transaction {get; set;}
```

See Also

[MySQLCommand Class](#) , [MySQL.Data.MySqlClient Namespace](#)

25.2.4.1.2.1.9. UpdatedRowSource Property

Syntax: Visual Basic

```
NotOverridable Public Property UpdatedRowSource As UpdateRowSource _  
- Implements IDbCommand.UpdatedRowSource
```

Syntax: C#

```
public System.Data.UpdateRowSource UpdatedRowSource {get; set;}
```

Implements

[IDbCommand.UpdatedRowSource](#)

See Also

[MySQLCommand Class](#) , [MySQL.Data.MySqlClient Namespace](#)

25.2.4.1.2.1.10. MySQLCommand.Cancel Method

Attempts to cancel the execution of a [MySQLCommand](#). This operation is not supported.

Syntax: Visual Basic

```
NotOverridable Public Sub Cancel() _  
- Implements IDbCommand.Cancel
```

Syntax: C#

```
public void Cancel();
```

Implements

IDbCommand.Cancel

Remarks

Cancelling an executing command is currently not supported on any version of MySQL.

Exceptions

Exception Type	Condition
NotSupportedException	This operation is not supported.

See Also

[MySQLCommand Class](#) , [MySql.Data.MySqlClient Namespace](#)

25.2.4.1.2.1.11. MySqlCommand.CreateParameter Method

Creates a new instance of a [MySQLParameter](#) object.

Syntax: Visual Basic

```
Public Function CreateParameter() As MySQLParameter
```

Syntax: C#

```
public MySQLParameter CreateParameter();
```

Return Value

A [MySQLParameter](#) object.

Remarks

This method is a strongly-typed version of CreateParameter.

See Also

[MySQLCommand Class](#) , [MySql.Data.MySqlClient Namespace](#)

25.2.4.1.2.1.12. MySqlCommand.ExecuteNonQuery Method

Syntax: Visual Basic

```
NotOverridable Public Function ExecuteNonQuery() As Integer _
    Implements IDbCommand.ExecuteNonQuery
```

Syntax: C#

```
public int ExecuteNonQuery();
```

Implements

IDbCommand.ExecuteNonQuery

See Also

[MySQLCommand Class](#) , [MySQL.Data.MySqlClient Namespace](#)

25.2.4.1.2.1.13. ExecuteReader Method

Overload List

- [public MySqlDataReader ExecuteReader\(\);](#)
- [public MySqlDataReader ExecuteReader\(CommandBehavior\);](#)

See Also

[MySQLCommand Class](#) , [MySQL.Data.MySqlClient Namespace](#)

25.2.4.1.2.1.13.1. MySqlCommand.ExecuteReader Method ()

Syntax: Visual Basic

```
Overloads Public Function ExecuteReader() As MySqlDataReader
```

Syntax: C#

```
public MySqlDataReader ExecuteReader();
```

See Also

[MySQLCommand Class](#) , [MySQL.Data.MySqlClient Namespace](#) , [MySQLCommand.ExecuteReader Overload List](#)

25.2.4.1.2.1.13.1.1. MySqlDataReader Class

Provides a means of reading a forward-only stream of rows from a MySQL database. This class cannot be inherited.

For a list of all members of this type, see [MySqlDataReader Members](#) .

Syntax: Visual Basic

```
NotInheritable Public Class MySqlDataReader_
    Inherits MarshalByRefObject_
    Implements IEnumerable, IDataReader, IDisposable, IDataRecord
```

Syntax: C#

```
public sealed class MySqlDataReader : MarshalByRefObject, IEnumerable, IDataReader, IDisposable, IDataRecord
```

Thread Safety

Public static (Shared in Visual Basic) members of this type are safe for multithreaded operations. Instance members are not guaranteed to be thread-safe.

Requirements

Namespace: [MySQL.Data.MySqlClient](#)

Assembly: MySQL.Data (in MySQL.Data.dll)

See Also

[MySqlDataReader Members](#) , [MySql.Data.MySqlClient Namespace](#)

25.2.4.1.2.1.13.1.1.1. MySqlDataReader Members

[MySqlDataReader overview](#)

Public Instance Properties

Depth	Gets a value indicating the depth of nesting for the current row. This method is not supported currently and always returns 0.
FieldCount	Gets the number of columns in the current row.
HasRows	Gets a value indicating whether the MySqlDataReader contains one or more rows.
IsClosed	Gets a value indicating whether the data reader is closed.
Item	Overloaded. Overloaded. Gets the value of a column in its native format. In C#, this property is the indexer for the MySqlDataReader class.
RecordsAffected	Gets the number of rows changed, inserted, or deleted by execution of the SQL statement.

Public Instance Methods

Close	Closes the MySqlDataReader object.
CreateObjRef(inherited from MarshalByRefObject)	Creates an object that contains all the relevant information required to generate a proxy used to communicate with a remote object.
Equals(inherited from Object)	Determines whether the specified Object is equal to the current Object.
GetBoolean	Gets the value of the specified column as a Boolean.
GetByte	Gets the value of the specified column as a byte.
GetBytes	Reads a stream of bytes from the specified column offset into the buffer an array starting at the given buffer offset.
GetChar	Gets the value of the specified column as a single character.
GetChars	Reads a stream of characters from the specified column offset into the buffer as an array starting at the given buffer offset.
GetDataTypeName	Gets the name of the source data type.
GetDateTime	
GetDecimal	
GetDouble	
GetFieldType	Gets the Type that is the data type of the object.
GetFloat	

GetGuid	
GetHashCode(inherited from Object)	Serves as a hash function for a particular type. GetHashCode is suitable for use in hashing algorithms and data structures like a hash table.
GetInt16	
GetInt32	
GetInt64	
GetLifetimeService(inherited from MarshalByRefObject)	Retrieves the current lifetime service object that controls the lifetime policy for this instance.
GetMySqlDateTime	
GetName	Gets the name of the specified column.
GetOrdinal	Gets the column ordinal, given the name of the column.
GetSchemaTable	Returns a DataTable that describes the column metadata of the MySqlDataReader.
GetString	
GetTimeSpan	
GetType(inherited from Object)	Gets the Type of the current instance.
GetUInt16	
GetUInt32	
GetUInt64	
GetValue	Gets the value of the specified column in its native format.
GetValues	Gets all attribute columns in the collection for the current row.
InitializeLifetimeService(inherited from MarshalByRefObject)	Obtains a lifetime service object to control the lifetime policy for this instance.
IsDBNull	Gets a value indicating whether the column contains non-existent or missing values.
NextResult	Advances the data reader to the next result, when reading the results of batch SQL statements.
Read	Advances the MySqlDataReader to the next record.
ToString(inherited from Object)	Returns a String that represents the current Object.

[MySqlDataReader Class](#) , [MySql.Data.MySqlClient Namespace](#)

25.2.4.1.2.1.13.1.1.1.1.1. Depth Property

Gets a value indicating the depth of nesting for the current row. This method is not supported currently and always returns 0.

Syntax: Visual Basic

```
NotOverridable Public ReadOnly Property Depth As Integer _
    Implements IDataReader.Depth
```

Syntax: C#

```
public int Depth {get;}
```

Implements

IDataReader.Depth

See Also

[MySQLDataReader Class](#) , [MySQL.Data.MySqlClient Namespace](#)

25.2.4.1.2.1.13.1.1.1.2. FieldCount Property

Gets the number of columns in the current row.

Syntax: Visual Basic

```
NotOverridable Public ReadOnly Property FieldCount As Integer _  
- Implements IDataRecord.FieldCount
```

Syntax: C#

```
public int FieldCount {get;}
```

Implements

IDataRecord.FieldCount

See Also

[MySQLDataReader Class](#) , [MySQL.Data.MySqlClient Namespace](#)

25.2.4.1.2.1.13.1.1.1.3. HasRows Property

Gets a value indicating whether the MySQLDataReader contains one or more rows.

Syntax: Visual Basic

```
Public ReadOnly Property HasRows As Boolean
```

Syntax: C#

```
public bool HasRows {get;}
```

See Also

[MySQLDataReader Class](#) , [MySQL.Data.MySqlClient Namespace](#)

25.2.4.1.2.1.13.1.1.1.4. IsClosed Property

Gets a value indicating whether the data reader is closed.

Syntax: Visual Basic

```
NotOverridable Public ReadOnly Property IsClosed As Boolean _  
- Implements IDataReader.IsClosed
```

Syntax: C#

```
public bool IsClosed {get;}
```

Implements

IDataReader.IsClosed

See Also

[MySQLDataReader Class](#) , [MySQL.Data.MySqlClient Namespace](#)

25.2.4.1.2.1.13.1.1.1.5. Item Property

Overloaded. Gets the value of a column in its native format. In C#, this property is the indexer for the MySQLDataReader class.

Overload List

Overloaded. Gets the value of a column in its native format. In C#, this property is the indexer for the MySQLDataReader class.

- [public object this\[int\] {get;}](#)

Gets the value of a column in its native format. In C#, this property is the indexer for the MySQLDataReader class.

- [public object this\[string\] {get;}](#)

See Also

[MySQLDataReader Class](#) , [MySQL.Data.MySqlClient Namespace](#)

25.2.4.1.2.1.13.1.1.1.5.1. Item Property (Int32)

Overloaded. Gets the value of a column in its native format. In C#, this property is the indexer for the MySQLDataReader class.

Syntax: Visual Basic

```
NotOverridable Overloads Public Default ReadOnly Property Item( _
    ByVal i As Integer _
) _
- Implements IDataRecord.Item As Object _
- Implements IDataRecord.Item
```

Syntax: C#

```
public object this[
    inti
] {get;}
```

Implements

IDataRecord.Item

See Also

[MySQLDataReader Class](#) , [MySQL.Data.MySqlClient Namespace](#) , [MySQLDataReader.Item Overload List](#)

25.2.4.1.2.1.13.1.1.1.5.2. Item Property (String)

Gets the value of a column in its native format. In C#, this property is the indexer for the MySQLDataReader class.

Syntax: Visual Basic

```
NotOverridable Overloads Public Default ReadOnly Property Item( _  
    ByVal name As String _  
) _  
- Implements IDataRecord.Item As Object _  
- Implements IDataRecord.Item
```

Syntax: C#

```
public object this[  
    stringname  
] {get;}
```

Implements

IDataRecord.Item

See Also

[MySQLDataReader Class](#) , [MySQL.Data.MySqlClient Namespace](#) , [MySQLDataReader.Item Overload List](#)

25.2.4.1.2.1.13.1.1.1.6. RecordsAffected Property

Gets the number of rows changed, inserted, or deleted by execution of the SQL statement.

Syntax: Visual Basic

```
NotOverridable Public ReadOnly Property RecordsAffected As Integer _  
- Implements IDataReader.RecordsAffected
```

Syntax: C#

```
public int RecordsAffected {get;}
```

Implements

IDataReader.RecordsAffected

See Also

[MySQLDataReader Class](#) , [MySQL.Data.MySqlClient Namespace](#)

25.2.4.1.2.1.13.1.1.1.7. MySQLDataReader.Close Method

Closes the MySQLDataReader object.

Syntax: Visual Basic

```
NotOverridable Public Sub Close() _  
    Implements IDataReader.Close
```

Syntax: C#

```
public void Close();
```

Implements

IDataReader.Close

See Also

[MySQLDataReader Class](#) , [MySQL.Data.MySqlClient Namespace](#)

25.2.4.1.2.1.13.1.1.1.8. MySQLDataReader.GetBoolean Method

Gets the value of the specified column as a Boolean.

Syntax: Visual Basic

```
NotOverridable Public Function GetBoolean( _  
    ByVal i As Integer _  
) As Boolean _  
    Implements IDataRecord.GetBoolean
```

Syntax: C#

```
public bool GetBoolean(  
    inti  
);
```

Parameters

- `i`:

Return Value**Implements**

IDataRecord.GetBoolean

See Also

[MySQLDataReader Class](#) , [MySQL.Data.MySqlClient Namespace](#)

25.2.4.1.2.1.13.1.1.1.9. MySQLDataReader.GetByte Method

Gets the value of the specified column as a byte.

Syntax: Visual Basic

```
NotOverridable Public Function GetByte( _  
    ByVal i As Integer _  
) As Byte _  
    Implements IDataRecord.GetByte
```

Syntax: C#

```
public byte GetByte(  
    inti  
);
```

Parameters

- `i`:

Return Value**Implements**

IDataRecord.GetByte

See Also

[MySqlDataReader Class](#) , [MySql.Data.MySqlClient Namespace](#)

25.2.4.1.2.1.13.1.1.1.10. MySqlDataReader.GetBytes Method

Reads a stream of bytes from the specified column offset into the buffer an array starting at the given buffer offset.

Syntax: Visual Basic

```
NotOverridable Public Function GetBytes( _  
    ByVal i As Integer, _  
    ByVal dataIndex As Long, _  
    ByVal buffer As Byte(), _  
    ByVal bufferIndex As Integer, _  
    ByVal length As Integer _  
) As Long _  
- Implements IDataRecord.GetBytes
```

Syntax: C#

```
public long GetBytes(  
    inti,  
    longdataIndex,  
    byte[]buffer,  
    intbufferIndex,  
    intlength  
);
```

Parameters

- `i`: The zero-based column ordinal.
- `dataIndex`: The index within the field from which to begin the read operation.
- `buffer`: The buffer into which to read the stream of bytes.
- `bufferIndex`: The index for buffer to begin the read operation.
- `length`: The maximum length to copy into the buffer.

Return Value

The actual number of bytes read.

Implements

IDataRecord.GetBytes

See Also

[MySQLDataReader Class](#) , [MySQL.Data.MySqlClient Namespace](#)

25.2.4.1.2.1.13.1.1.11. MySQLDataReader.GetChar Method

Gets the value of the specified column as a single character.

Syntax: Visual Basic

```
NotOverridable Public Function GetChar( _  
    ByVal i As Integer _  
) As Char _  
- Implements IDataRecord.GetChar
```

Syntax: C#

```
public char GetChar(  
    inti  
);
```

Parameters

- *i*:

Return Value**Implements**

IDataRecord.GetChar

See Also

[MySQLDataReader Class](#) , [MySQL.Data.MySqlClient Namespace](#)

25.2.4.1.2.1.13.1.1.12. MySQLDataReader.GetChars Method

Reads a stream of characters from the specified column offset into the buffer as an array starting at the given buffer offset.

Syntax: Visual Basic

```
NotOverridable Public Function GetChars( _  
    ByVal i As Integer, _  
    ByVal fieldOffset As Long, _  
    ByVal buffer As Char(), _  
    ByVal bufferoffset As Integer, _  
    ByVal length As Integer _  
) As Long _  
- Implements IDataRecord.GetChars
```

Syntax: C#

```
public long GetChars(  
    inti,  
    longfieldOffset,  
    char[]buffer,  
    intbufferoffset,  
    intlength  
);
```

Parameters

- `i`:
- `fieldOffset`:
- `buffer`:
- `bufferoffset`:
- `length`:

Return Value**Implements**

IDataRecord.GetChars

See Also

[MySQLDataReader Class](#) , [MySql.Data.MySqlClient Namespace](#)

25.2.4.1.2.1.13.1.1.1.13. MySQLDataReader.GetDataTypeName Method

Gets the name of the source data type.

Syntax: Visual Basic

```
NotOverridable Public Function GetDataTypeName( _  
    ByVal i As Integer _  
) As String _  
— Implements IDataRecord.GetDataTypeName
```

Syntax: C#

```
public string GetDataTypeName(  
    inti  
);
```

Parameters

- `i`:

Return Value**Implements**

IDataRecord.GetDataTypeName

See Also

[MySQLDataReader Class](#) , [MySQL.Data.MySqlClient Namespace](#)

25.2.4.1.2.1.13.1.1.1.14. MySQLDataReader.GetDateTime Method

Syntax: Visual Basic

```
NotOverridable Public Function GetDateTime( _  
    ByVal index As Integer _  
) As Date _  
- Implements IDataRecord.GetDateTime
```

Syntax: C#

```
public DateTime GetDateTime(  
    int index  
);
```

Implements

IDataRecord.GetDateTime

See Also

[MySQLDataReader Class](#) , [MySQL.Data.MySqlClient Namespace](#)

25.2.4.1.2.1.13.1.1.1.15. MySQLDataReader.GetDecimal Method

Syntax: Visual Basic

```
NotOverridable Public Function GetDecimal( _  
    ByVal index As Integer _  
) As Decimal _  
- Implements IDataRecord.GetDecimal
```

Syntax: C#

```
public decimal GetDecimal(  
    int index  
);
```

Implements

IDataRecord.GetDecimal

See Also

[MySQLDataReader Class](#) , [MySQL.Data.MySqlClient Namespace](#)

25.2.4.1.2.1.13.1.1.1.16. MySQLDataReader.GetDouble Method

Syntax: Visual Basic

```
NotOverridable Public Function GetDouble( _  
    ByVal index As Integer _  
) As Double _  
- Implements IDataRecord.GetDouble
```

Syntax: C#

```
public double GetDouble(  
int index  
);
```

Implements

IDataRecord.GetDouble

See Also

[MySQLDataReader Class](#) , [MySQL.Data.MySqlClient Namespace](#)

25.2.4.1.2.1.13.1.1.1.17. MySQLDataReader.GetFieldType Method

Gets the Type that is the data type of the object.

Syntax: Visual Basic

```
NotOverridable Public Function GetFieldType( _  
ByVal i As Integer _  
) As Type _  
— Implements IDataRecord.GetFieldType
```

Syntax: C#

```
public Type GetFieldType(  
int i  
);
```

Parameters

- *i*:

Return Value**Implements**

IDataRecord.GetFieldType

See Also

[MySQLDataReader Class](#) , [MySQL.Data.MySqlClient Namespace](#)

25.2.4.1.2.1.13.1.1.1.18. MySQLDataReader.GetFloat Method

Syntax: Visual Basic

```
NotOverridable Public Function GetFloat( _  
ByVal index As Integer _  
) As Single _  
— Implements IDataRecord.GetFloat
```

Syntax: C#

```
public float GetFloat(  
int index
```

```
);
```

Implements

IDataRecord.GetFloat

See Also[MySQLDataReader Class](#) , [MySQL.Data.MySqlClient Namespace](#)

25.2.4.1.2.1.13.1.1.1.19. MySQLDataReader.GetGuid Method

Syntax: Visual Basic

```
NotOverridable Public Function GetGuid( _  
    ByVal index As Integer _  
) As Guid _  
Implements IDataRecord.GetGuid
```

Syntax: C#

```
public Guid GetGuid(  
    int index  
);
```

Implements

IDataRecord.GetGuid

See Also[MySQLDataReader Class](#) , [MySQL.Data.MySqlClient Namespace](#)

25.2.4.1.2.1.13.1.1.1.20. MySQLDataReader.GetInt16 Method

Syntax: Visual Basic

```
NotOverridable Public Function GetInt16( _  
    ByVal index As Integer _  
) As Short _  
Implements IDataRecord.GetInt16
```

Syntax: C#

```
public short GetInt16(  
    int index  
);
```

Implements

IDataRecord.GetInt16

See Also[MySQLDataReader Class](#) , [MySQL.Data.MySqlClient Namespace](#)

25.2.4.1.2.1.13.1.1.1.21. MySQLDataReader.GetInt32 Method

Syntax: Visual Basic

```
NotOverridable Public Function GetInt32( _  
    ByVal index As Integer _  
) As Integer _  
- Implements IDataRecord.GetInt32
```

Syntax: C#

```
public int GetInt32(  
    int index  
);
```

Implements

IDataRecord.GetInt32

See Also

[MySQLDataReader Class](#), [MySQL.Data.MySqlClient Namespace](#)

25.2.4.1.2.1.13.1.1.1.22. MySQLDataReader.GetInt64 Method

Syntax: Visual Basic

```
NotOverridable Public Function GetInt64( _  
    ByVal index As Integer _  
) As Long _  
- Implements IDataRecord.GetInt64
```

Syntax: C#

```
public long GetInt64(  
    int index  
);
```

Implements

IDataRecord.GetInt64

See Also

[MySQLDataReader Class](#), [MySQL.Data.MySqlClient Namespace](#)

25.2.4.1.2.1.13.1.1.1.23. MySQLDataReader.GetMySqlDateTime Method

Syntax: Visual Basic

```
Public Function GetMySqlDateTime( _  
    ByVal index As Integer _  
) As MySqlDateTime
```

Syntax: C#

```
public MySqlDateTime GetMySqlDateTime(  
    int index  
);
```

See Also

[MySQLDataReader Class](#), [MySQL.Data.MySqlClient Namespace](#)

25.2.4.1.2.1.13.1.1.1.24. MySqlCommandReader.GetName Method

Gets the name of the specified column.

Syntax: Visual Basic

```
NotOverridable Public Function GetName( _  
    ByVal i As Integer _  
) As String _  
- Implements IDataRecord.GetName
```

Syntax: C#

```
public string GetName(  
    inti  
);
```

Parameters

- `i`:

Return Value

Implements

IDataRecord.GetName

See Also

[MySqlCommandReader Class](#) , [MySql.Data.MySqlClient Namespace](#)

25.2.4.1.2.1.13.1.1.1.25. MySqlCommandReader.GetOrdinal Method

Gets the column ordinal, given the name of the column.

Syntax: Visual Basic

```
NotOverridable Public Function GetOrdinal( _  
    ByVal name As String _  
) As Integer _  
- Implements IDataRecord.GetOrdinal
```

Syntax: C#

```
public int GetOrdinal(  
    stringname  
);
```

Parameters

- `name`:

Return Value

Implements

IDataRecord.GetOrdinal

See Also

[MySQLDataReader Class](#) , [MySQL.Data.MySqlClient Namespace](#)

25.2.4.1.2.1.13.1.1.1.26. MySQLDataReader.GetSchemaTable Method

Returns a DataTable that describes the column metadata of the MySQLDataReader.

Syntax: Visual Basic

```
NotOverridable Public Function GetSchemaTable() As DataTable _  
    Implements IDataReader.GetSchemaTable
```

Syntax: C#

```
public DataTable GetSchemaTable();
```

Return Value

Implements

IDataReader.GetSchemaTable

Syntax: C#

```
public ulong GetUInt64(  
    int index  
);
```

See Also

[MySQLDataReader Class](#) , [MySQL.Data.MySqlClient Namespace](#)

25.2.4.1.2.1.13.1.1.1.32. MySQLDataReader.GetValue Method

Gets the value of the specified column in its native format.

Syntax: Visual Basic

```
NotOverridable Public Function GetValue( _  
    ByVal i As Integer _  
) As Object _  
- Implements IDataRecord.GetValue
```

Syntax: C#

```
public object GetValue(  
    inti  
);
```

Parameters

- `i`:

Return Value**Implements**

IDataRecord.GetValue

See Also

[MySQLDataReader Class](#) , [MySQL.Data.MySqlClient Namespace](#)

25.2.4.1.2.1.13.1.1.1.33. MySQLDataReader.GetValues Method

Gets all attribute columns in the collection for the current row.

Syntax: Visual Basic

```
NotOverridable Public Function GetValues( _  
    ByVal values As Object() _  
) As Integer _  
- Implements IDataRecord.GetValues
```

Syntax: C#

```
public int GetValues(  
    object[] values  
);
```

Parameters

- `values`:

Return Value**Implements**

IDataRecord.GetValues

See Also[MySQLDataReader Class](#) , [MySql.Data.MySqlClient Namespace](#)

25.2.4.1.2.1.13.1.1.1.34. MySQLDataReader.IsDBNull Method

Gets a value indicating whether the column contains non-existent or missing values.

Syntax: Visual Basic

```
NotOverridable Public Function IsDBNull( _  
    ByVal i As Integer _  
) As Boolean _  
- Implements IDataRecord.IsDBNull
```

Syntax: C#

```
public bool IsDBNull(  
    inti  
);
```

Parameters

- `i`:

Return Value**Implements**

IDataRecord.IsDBNull

See Also[MySQLDataReader Class](#) , [MySql.Data.MySqlClient Namespace](#)

25.2.4.1.2.1.13.1.1.1.35. MySQLDataReader.NextResult Method

Advances the data reader to the next result, when reading the results of batch SQL statements.

Syntax: Visual Basic

```
NotOverridable Public Function NextResult() As Boolean _  
- Implements IDataReader.NextResult
```

Syntax: C#

```
public bool NextResult();
```

Return Value

Implements

IDataReader.NextResult

See Also

[MySQLDataReader Class](#) , [MySQL.Data.MySqlClient Namespace](#)

25.2.4.1.2.1.13.1.1.36. MySQLDataReader.Read Method

Advances the MySQLDataReader to the next record.

Syntax: Visual Basic

```
NotOverridable Public Function Read() As Boolean _  
    Implements IDataReader.Read
```

Syntax: C#

```
public bool Read();
```

Return Value**Implements**

IDataReader.Read

See Also

[MySQLDataReader Class](#) , [MySQL.Data.MySqlClient Namespace](#)

25.2.4.1.2.1.13.2. MySqlCommand.ExecuteReader Method (CommandBehavior)

Syntax: Visual Basic

```
Overloads Public Function ExecuteReader( _  
    ByVal behavior As CommandBehavior _  
) As MySQLDataReader
```

Syntax: C#

```
public MySQLDataReader ExecuteReader(  
    CommandBehaviorbehavior  
);
```

25.2.4.1.3. MySQLCommandBuilder Class

For a list of all members of this type, see [MySQLCommandBuilder Members](#) .

Syntax: Visual Basic

```
NotInheritable Public Class MySQLCommandBuilder_  
    Inherits Component
```

Syntax: C#

```
public sealed class MySQLCommandBuilder : Component
```

Thread Safety

Public static (Shared in Visual Basic) members of this type are safe for multithreaded operations. Instance members are not guaranteed to be thread-safe.

Requirements

Namespace: [MySQL.Data.MySqlClient](#)

Assembly: MySQL.Data (in MySQL.Data.dll)

See Also

[MySQLCommandBuilder Members](#) , [MySQL.Data.MySqlClient Namespace](#)

25.2.4.1.3.1. MySqlCommandBuilder Members

[MySqlCommandBuilder overview](#)

Public Static (Shared) Methods

DeriveParameters	Overloaded. Retrieves parameter information from the stored procedure specified in the MySqlCommand and populates the Parameters collection of the specified MySqlCommand object. This method is not currently supported since stored procedures are not available in MySQL.
----------------------------------	--

Public Instance Constructors

MySqlCommandBuilder	Overloaded. Initializes a new instance of the MySqlCommandBuilder class.
-------------------------------------	--

Public Instance Properties

Container(inherited from Component)	Gets the IContainer that contains the Component.
DataAdapter	
QuotePrefix	
QuoteSuffix	
Site(inherited from Component)	Gets or sets the ISite of the Component.

Public Instance Methods

CreateObjRef(inherited from MarshalByRefObject)	Creates an object that contains all the relevant information required to generate a proxy used to communicate with a remote object.
Dispose(inherited from Component)	Releases all resources used by the Component.
Equals(inherited from Object)	Determines whether the specified Object is equal to the current Object.
GetDeleteCommand	
GetHashCode(inherited from Object)	Serves as a hash function for a particular type. GetHashCode is suitable for use in hashing algorithms and data structures like a hash table.
GetInsertCommand	
GetLifetimeService(inherited from MarshalByRefObject)	Retrieves the current lifetime service object that controls the lifetime policy for this instance.
GetType(inherited from Object)	Gets the Type of the current instance.
GetUpdateCommand	
InitializeLifetimeService(inherited from MarshalByRefObject)	Obtains a lifetime service object to control the lifetime policy for this instance.
RefreshSchema	
ToString(inherited from Component)	Returns a String containing the name of the Component, if any. This method should not be overrid-

	den.
--	------

Public Instance Events

Disposed(inherited from Component)	Adds an event handler to listen to the Dispose- devent on the component.
------------------------------------	---

See Also

[MySQLCommandBuilder Class](#) , [MySQL.Data.MySqlClient Namespace](#)

25.2.4.1.3.1.1. DeriveParameters Method

Retrieves parameter information from the stored procedure specified in the MySqlCommand and populates the Parameters collection of the specified MySqlCommand object. This method is not currently supported since stored procedures are not available in MySQL.

Overload List

Retrieves parameter information from the stored procedure specified in the MySqlCommand and populates the Parameters collection of the specified MySqlCommand object. This method is not currently supported since stored procedures are not available in MySQL.

- [public static void DeriveParameters\(MySqlCommand\);](#)
- [public static void DeriveParameters\(MySqlCommand,bool\);](#)

See Also

[MySQLCommandBuilder Class](#) , [MySQL.Data.MySqlClient Namespace](#)

25.2.4.1.3.1.1.1. MySqlCommandBuilder.DeriveParameters Method (MySqlCommand)

Retrieves parameter information from the stored procedure specified in the MySqlCommand and populates the Parameters collection of the specified MySqlCommand object. This method is not currently supported since stored procedures are not available in MySQL.

Syntax: Visual Basic

```
Overloads Public Shared Sub DeriveParameters( _
    ByVal command As MySqlCommand _
)
```

Syntax: C#

```
public static void DeriveParameters(
    MySqlCommandcommand
);
```

Parameters

- [command](#): The MySqlCommand referencing the stored procedure from which the parameter information is to be derived. The derived parameters are added to the Parameters collection of the MySqlCommand.

Exceptions

Exception Type	Condition
InvalidOperationException	The command text is not a valid stored procedure name.

25.2.4.1.3.1.1.2. MySQLCommandBuilder.DeriveParameters Method (MySQLCommand, Boolean)

Syntax: Visual Basic

```
Overloads Public Shared Sub DeriveParameters( _
    ByVal command As MySQLCommand, _
    ByVal useProc As Boolean _
)
```

Syntax: C#

```
public static void DeriveParameters(
    MySQLCommand command,
    bool useProc
);
```

[MySqlDataAdapter Members](#) , [MySql.Data.MySqlClient Namespace](#)

25.2.4.1.3.1.2.2.1.1. MySqlDataAdapter Members

[MySqlDataAdapter overview](#)**Public Instance Constructors**

MySqlDataAdapter	Overloaded. Initializes a new instance of the MySqlDataAdapter class.
----------------------------------	---

Public Instance Properties

AcceptChangesDuringFill(inherited from DataAdapter)	Gets or sets a value indicating whether AcceptChanges is called on a DataRow after it is added to the DataTable during any of the Fill operations.
AcceptChangesDuringUpdate(inherited from DataAdapter)	Gets or sets whether AcceptChanges is called during a Update.
Container(inherited from Component)	Gets the IContainer that contains the Component.
ContinueUpdateOnError(inherited from DataAdapter)	Gets or sets a value that specifies whether to generate an exception when an error is encountered during a row update.
DeleteCommand	Overloaded.
FillLoadOption(inherited from DataAdapter)	Gets or sets the LoadOption that determines how the adapter fills the DataTable from the DbDataReader.
InsertCommand	Overloaded.
MissingMappingAction(inherited from DataAdapter)	Determines the action to take when incoming data does not have a matching table or column.
MissingSchemaAction(inherited from DataAdapter)	Determines the action to take when existing DataSet schema does not match incoming data.
ReturnProviderSpecificTypes(inherited from DataAdapter)	Gets or sets whether the Fill method should return provider-specific values or common CLS-compliant values.
SelectCommand	Overloaded.
Site(inherited from Component)	Gets or sets the ISite of the Component.
TableMappings(inherited from DataAdapter)	Gets a collection that provides the master mapping between a source table and a DataTable.
UpdateBatchSize(inherited from DbDataAdapter)	Gets or sets a value that enables or disables batch processing support, and specifies the number of commands that can be executed in a batch.
UpdateCommand	Overloaded.

Public Instance Methods

CreateObjRef(inherited from MarshalByRefObject)	Creates an object that contains all the relevant information required to generate a proxy used to communicate with a remote object.
Dispose(inherited from Component)	Releases all resources used by the Component.
Equals(inherited from Object)	Determines whether the specified Object is equal to the current Object.

Fill(inherited from DbDataAdapter)	Overloaded. Adds or refreshes rows in the DataSet to match those in the data source using the DataSetname, and creates a DataTable named "Table."
FillSchema(inherited from DbDataAdapter)	Overloaded. Configures the schema of the specified DataTable based on the specified SchemaType.
GetFillParameters(inherited from DbDataAdapter)	Gets the parameters set by the user when executing an SQL <code>SELECT</code> statement.
GetHashCode(inherited from Object)	Serves as a hash function for a particular type. GetHashCode is suitable for use in hashing algorithms and data structures like a hash table.
GetLifetimeService(inherited from MarshalByRefObject)	Retrieves the current lifetime service object that controls the lifetime policy for this instance.
GetType(inherited from Object)	Gets the Type of the current instance.
InitializeLifetimeService(inherited from MarshalByRefObject)	Obtains a lifetime service object to control the lifetime policy for this instance.
ResetFillLoadOption(inherited from DataAdapter)	Resets FillLoadOption to its default state and causes Fill to honor AcceptChangesDuringFill.
ShouldSerializeAcceptChangesDuringFill(inherited from DataAdapter)	Determines whether the AcceptChangesDuringFill property should be persisted.
ShouldSerializeFillLoadOption(inherited from DataAdapter)	Determines whether the FillLoadOption property should be persisted.
ToString(inherited from Component)	Returns a String containing the name of the Component, if any. This method should not be overridden.
Update(inherited from DbDataAdapter)	Overloaded. Calls the respective INSERT, UPDATE, or DELETE statements for each inserted, updated, or deleted row in the specified DataSet.

Public Instance Events

Disposed(inherited from Component)	Adds an event handler to listen to the Dispose event on the component.
FillError(inherited from DataAdapter)	Returned when an error occurs during a fill operation.
RowUpdated	Occurs during Update after a command is executed against the data source. The attempt to update is made, so the event fires.
RowUpdating	Occurs during Update before a command is executed against the data source. The attempt to update is made, so the event fires.

Protected Internal Instance Properties

FillCommandBehavior(inherited from DbDataAdapter)	Gets or sets the behavior of the command used to fill the data adapter.

25.2.4.1.3.1.2.2.1.1.6. MySqlCommandAdapter.RowUpdated Event

Occurs during Update after a command is executed against the data source. The attempt to update is made, so the event fires.

Syntax: Visual Basic

```
Public Event RowUpdated As MySqlRowUpdatedEventHandler
```

Syntax: C#

```
public event MySqlRowUpdatedEventHandler RowUpdated;
```

Event Data

The event handler receives an argument of type [MySqlRowUpdatedEventArgs](#) containing data related to

this event. The following `MySqlRowUpdatedEventArgs` properties provide information specific to this event.

Property	Description
Command	Gets or sets the <code>MySqlCommand</code> executed when <code>Update</code> is called.
Errors	Gets any errors generated by the .NET Framework data provider when the <code>Command</code> was executed.
RecordsAffected	Gets the number of rows changed, inserted, or deleted by execution of the SQL statement.
Row	Gets the <code>DataRow</code> sent through an <code>Update</code> .
RowCount	Gets the number of rows processed in a batch of updated records.
StatementType	Gets the type of SQL statement executed.
Status	Gets the <code>UpdateStatus</code> of the <code>Command</code> property.
TableMapping	Gets the <code>DataTableMapping</code> sent through an <code>Update</code> .

25.2.4.1.3.1.2.2.1.1.6.1. MySqlRowUpdatedEventHandler Delegate

Represents the method that will handle the `RowUpdated` event of a [MySqlDataAdapter](#) .

Syntax: Visual Basic

```
Public Delegate Sub MySqlRowUpdatedEventHandler( _
    ByVal sender As Object, _
    ByVal e As MySqlRowUpdatedEventArgs _
)
```

Syntax: C#

```
public delegate void MySqlRowUpdatedEventHandler(
    object sender,
    MySqlRowUpdatedEventArgs
);
```

Requirements

Namespace: [MySql.Data.MySqlClient](#)

Assembly: `MySql.Data` (in `MySql.Data.dll`)

See Also

[MySql.Data.MySqlClient Namespace](#)

25.2.4.1.3.1.2.2.1.1.6.1.1. MySqlRowUpdatedEventArgs Class

Provides data for the `RowUpdated` event. This class cannot be inherited.

For a list of all members of this type, see [MySqlRowUpdatedEventArgs Members](#) .

Syntax: Visual Basic

```
NotInheritable Public Class MySqlRowUpdatedEventArgs_
    Inherits RowUpdatedEventArgs
```

Syntax: C#

```
public sealed class MySqlRowUpdatedEventArgs : RowUpdatedEventArgs
```

Thread Safety

Public static (Shared in Visual Basic) members of this type are safe for multithreaded operations. Instance members are not guaranteed to be thread-safe.

Requirements

Namespace: [MySql.Data.MySqlClient](#)

Assembly: MySql.Data (in MySql.Data.dll)

[MySqlRowUpdatedEventArgs overview](#)

Public Instance Constructors

MySqlRowUpdatedEventArgs Constructor	Initializes a new instance of the MySqlRowUpdatedEventArgs class.
--	---

Public Instance Properties

Command	Overloaded. Gets or sets the MySqlCommand executed when Update is called.
Errors(inherited from RowUpdatedEventArgs)	Gets any errors generated by the .NET Framework data provider when the Command was executed.
RecordsAffected(inherited from RowUpdatedEventArgs)	Gets the number of rows changed, inserted, or deleted by execution of the SQL statement.
Row(inherited from RowUpdatedEventArgs)	Gets the DataRow sent through an Update.
RowCount(inherited from RowUpdatedEventArgs)	Gets the number of rows processed in a batch of updated records.
StatementType(inherited from RowUpdatedEventArgs)	Gets the type of SQL statement executed.
Status(inherited from RowUpdatedEventArgs)	Gets the UpdateStatus of the Command property.
TableMapping(inherited from RowUpdatedEventArgs)	Gets the DataTableMapping sent through an Update.

Public Instance Methods

CopyToRows(inherited from RowUpdatedEventArgs)	Overloaded. Copies references to the modified
--	---

Args)	rows into the provided array.
Equals(inherited from Object)	Determines whether the specified Object is equal to the current Object.
GetHashCode(inherited from Object)	Serves as a hash function for a particular type. GetHashCode is suitable for use in hashing algorithms and data structures like a hash table.
GetType(inherited from Object)	Gets the Type of the current instance.
ToString(inherited from Object)	Returns a String that represents the current Object.

[MySQLRowUpdatedEventArgs Class](#) , [MySQL.Data.MySqlClient Namespace](#)

25.2.4.1.3.1.2.2.1.1.6.1.1.1.1. MySQLRowUpdatedEventArgs Constructor

Initializes a new instance of the MySQLRowUpdatedEventArgs class.

Syntax: Visual Basic

```
Public Sub New( _
    ByVal row As DataRow, _
    ByVal command As IDbCommand, _
    ByVal statementType As StatementType, _
    ByVal tableMapping As DataTableMapping _
)
```

Syntax: C#

```
public MySQLRowUpdatedEventArgs(
    DataRow row,
    IDbCommand command,
    StatementType statementType,
    DataTableMapping tableMapping
);
```

Parameters

- **row**: The DataRow sent through an Update.
- **command**: The IDbCommand executed when Update is called.
- **statementType**: One of the StatementType values that specifies the type of query executed.
- **tableMapping**: The DataTableMapping sent through an Update.

25.2.4.1.3.1.2.2.1.1.6.1.1.1.2. Command Property

Gets or sets the MySqlCommand executed when Update is called.

Syntax: Visual Basic

```
Overloads Public ReadOnly Property Command As MySqlCommand
```

Syntax: C#

```
new public MySqlCommand Command {get;}
```

See Also

[MySqlRowUpdatedEventArgs Class](#) , [MySql.Data.MySqlClient Namespace](#)

25.2.4.1.3.1.2.2.1.1.7. MySqlDataAdapter.RowUpdating Event

Occurs during Update before a command is executed against the data source. The attempt to update is made, so the event fires.

Syntax: Visual Basic

```
Public Event RowUpdating As MySqlRowUpdatingEventHandler
```

Syntax: C#

```
public event MySqlRowUpdatingEventHandler RowUpdating;
```

Event Data

The event handler receives an argument of type [MySqlRowUpdatingEventArgs](#) containing data related to this event. The following [MySqlRowUpdatingEventArgs](#) properties provide information specific to this event.

Property	Description
Command	Gets or sets the MySqlCommand to execute when performing the Update.
Errors	Gets any errors generated by the .NET Framework data provider when the Command executes.
Row	Gets the DataRow that will be sent to the server as part of an insert, update, or delete operation.
StatementType	Gets the type of SQL statement to execute.
Status	Gets or sets the UpdateStatus of the Command-property.
TableMapping	Gets the DataTableMapping to send through the Update.

25.2.4.1.3.1.2.2.1.1.7.1.1. MySqlRowUpdatingEventArgs Class

Provides data for the RowUpdating event. This class cannot be inherited.

For a list of all members of this type, see [MySqlRowUpdatingEventArgs Members](#) .

Syntax: Visual Basic

```
NotInheritable Public Class MySqlRowUpdatingEventArgs_
    Inherits RowUpdatingEventArgs
```

Syntax: C#

```
public sealed class MySqlRowUpdatingEventArgs : RowUpdatingEventArgs
```

Thread Safety

Public static (Shared in Visual Basic) members of this type are safe for multithreaded operations. Instance members are not guaranteed to be thread-safe.

Requirements

Namespace: [MySql.Data.MySqlClient](#)

Assembly: MySql.Data (in MySql.Data.dll)

See Also

[MySqlRowUpdatingEventArgs Members](#) , [MySql.Data.MySqlClient Namespace](#)

[MySqlRowUpdatingEventArgs overview](#)

Public Instance Constructors

MySqlRowUpdatingEventArgs Constructor	Initializes a new instance of the MySqlRowUpdatingEventArgs class.
---	--

Public Instance Properties

Command	Overloaded. Gets or sets the MySqlCommand to execute when performing the Update.
Errors(inherited from RowUpdatingEventArgs)	Gets any errors generated by the .NET Framework data provider when the Command executes.
Row(inherited from RowUpdatingEventArgs)	Gets the DataRow that will be sent to the server as part of an insert, update, or delete operation.
StatementType(inherited from RowUpdatingEventArgs)	Gets the type of SQL statement to execute.
Status(inherited from RowUpdatingEventArgs)	Gets or sets the UpdateStatus of the Command property.
TableMapping(inherited from RowUpdatingEventArgs)	Gets the DataTableMapping to send through the Update.

Public Instance Methods

Equals(inherited from Object)	Determines whether the specified Object is equal to the current Object.
GetHashCode(inherited from Object)	Serves as a hash function for a particular type. GetHashCode is suitable for use in hashing algorithms and data structures like a hash table.
GetType(inherited from Object)	Gets the Type of the current instance.
ToString(inherited from Object)	Returns a String that represents the current Object.

[MySQLRowUpdatingEventArgs Class](#) , [MySQL.Data.MySqlClient Namespace](#)

25.2.4.1.3.1.2.2.1.1.7.1.1.1.1. MySQLRowUpdatingEventArgs Constructor

Initializes a new instance of the MySQLRowUpdatingEventArgs class.

Syntax: Visual Basic

```
Public Sub New( _
    ByVal row As DataRow, _
    ByVal command As IDbCommand, _
    ByVal statementType As StatementType, _
    ByVal tableMapping As DataTableMapping _
)
```

Syntax: C#

```
public MySQLRowUpdatingEventArgs(
    DataRow row,
    IDbCommand command,
    StatementType statementType,
    DataTableMapping tableMapping
);
```

Parameters

- **row**: The DataRow to Update.
- **command**: The IDbCommand to execute during Update.

- `statementType`: One of the `StatementType` values that specifies the type of query executed.
- `tableMapping`: The `DataTableMapping` sent through an `Update`.

[MySQLRowUpdatingEventArgs Class](#) , [MySQL.Data.MySqlCommand Namespace](#)

25.2.4.1.3.1.2.2.1.1.7.1.1.1.2. Command Property

Gets or sets the `SqlCommand` to execute when performing the `Update`.

Syntax: Visual Basic

```
Overloads Public Property Command As MySqlCommand
```

Syntax: C#

```
new public MySqlCommand Command {get; set;}
```

See Also

[MySQLRowUpdatingEventArgs Class](#) , [MySQL.Data.MySqlCommand Namespace](#)

25.2.4.1.3.1.2.3. MySqlCommandBuilder Constructor (MySqlDataAdapter, Boolean)

Syntax: Visual Basic

```
Overloads Public Sub New( _  
    ByVal adapter As MySqlDataAdapter, _  
    ByVal lastOneWins As Boolean _  
)
```

Syntax: C#

```
public MySqlCommandBuilder(  
    MySqlDataAdapter adapter,  
    boollastOneWins  
);
```

Syntax: Visual Basic

```
Public Function GetDeleteCommand() As MySqlCommand
```

Syntax: C#

```
public MySqlCommand GetDeleteCommand();
```

See Also

[MySqlCommandBuilder Class](#) , [MySql.Data.MySqlClient Namespace](#)

25.2.4.1.3.1.7. MySqlCommandBuilder.GetInsertCommand Method

Syntax: Visual Basic

```
Public Function GetInsertCommand() As MySqlCommand
```

Syntax: C#

```
public MySqlCommand GetInsertCommand();
```

See Also

[MySqlCommandBuilder Class](#) , [MySql.Data.MySqlClient Namespace](#)

25.2.4.1.3.1.8. MySqlCommandBuilder.GetUpdateCommand Method

Syntax: Visual Basic

```
Public Function GetUpdateCommand() As MySqlCommand
```

Syntax: C#

```
public MySqlCommand GetUpdateCommand();
```

See Also

[MySqlCommandBuilder Class](#) , [MySql.Data.MySqlClient Namespace](#)

25.2.4.1.3.1.9. MySqlCommandBuilder.RefreshSchema Method

Syntax: Visual Basic

```
Public Sub RefreshSchema()
```

Syntax: C#

```
public void RefreshSchema();
```

See Also

[MySqlCommandBuilder Class](#) , [MySql.Data.MySqlClient Namespace](#)

25.2.4.1.4. MySqlConnectionException Class

The exception that is thrown when MySQL returns an error. This class cannot be inherited.

For a list of all members of this type, see [MySqlConnectionException Members](#) .

Syntax: Visual Basic

```
NotInheritable Public Class MySqlConnectionException_  
    Inherits SystemException
```

Syntax: C#

```
public sealed class MySqlConnection : SystemException
```

Thread Safety

Public static (Shared in Visual Basic) members of this type are safe for multithreaded operations. Instance members are not guaranteed to be thread-safe.

Requirements

Namespace: [MySql.Data.MySqlClient](#)

Assembly: MySql.Data (in MySql.Data.dll)

See Also

[MySqlConnection Members](#) , [MySql.Data.MySqlClient Namespace](#)

25.2.4.1.4.1. MySqlConnection Members

[MySqlConnection overview](#)

Public Instance Properties

Data(inherited from Exception)	Gets a collection of key/value pairs that provide additional, user-defined information about the exception.
HelpLink(inherited from Exception)	Gets or sets a link to the help file associated with this exception.
InnerException(inherited from Exception)	Gets the Exception instance that caused the current exception.
Message(inherited from Exception)	Gets a message that describes the current exception.
Number	Gets a number that identifies the type of error.
Source(inherited from Exception)	Gets or sets the name of the application or the object that causes the error.
StackTrace(inherited from Exception)	Gets a string representation of the frames on the call stack at the time the current exception was thrown.
TargetSite(inherited from Exception)	Gets the method that throws the current exception.

Public Instance Methods

Equals(inherited from Object)	Determines whether the specified Object is equal to the current Object.
GetBaseException(inherited from Exception)	When overridden in a derived class, returns the Exception that is the root cause of one or more subsequent exceptions.
GetHashCode(inherited from Object)	Serves as a hash function for a particular type. GetHashCode is suitable for use in hashing algorithms and data structures like a hash table.
GetObjectData(inherited from Exception)	When overridden in a derived class, sets the Serial-

	izationInfo with information about the exception.
GetType(inherited from Exception)	Gets the runtime type of the current instance.
ToString(inherited from Exception)	Creates and returns a string representation of the current exception.

[MySqlException Class](#) , [MySql.Data.MySqlClient Namespace](#)

25.2.4.1.4.1.1. Number Property

Gets a number that identifies the type of error.

Syntax: Visual Basic

```
Public ReadOnly Property Number As Integer
```

Syntax: C#

```
public int Number {get;}
```

See Also

[MySqlException Class](#) , [MySql.Data.MySqlClient Namespace](#)

25.2.4.1.5. MySqlHelper Class

Helper class that makes it easier to work with the provider.

For a list of all members of this type, see [MySqlHelper Members](#) .

Syntax: Visual Basic

```
NotInheritable Public Class MySqlHelper
```

Syntax: C#

```
public sealed class MySqlHelper
```

Thread Safety

Public static (Shared in Visual Basic) members of this type are safe for multithreaded operations. Instance members are not guaranteed to be thread-safe.

Requirements

Namespace: [MySql.Data.MySqlClient](#)

Assembly: MySql.Data (in MySql.Data.dll)

See Also

[MySqlHelper Members](#) , [MySql.Data.MySqlClient Namespace](#)

25.2.4.1.5.1. MySqlHelper Members

[MySqlHelper overview](#)**Public Static (Shared) Methods**

ExecuteDataRow	Executes a single SQL command and returns the first row of the resultset. A new MySqlConnection object is created, opened, and closed during this method.
ExecuteDataset	Overloaded. Executes a single SQL command and returns the resultset in a DataSet. A new MySqlConnection object is created, opened, and closed during this method.
ExecuteNonQuery	Overloaded. Executes a single command against a MySQL database. The MySqlConnection is assumed to be open when the method is called and remains open after the method completes.
ExecuteReader	Overloaded. Executes a single command against a MySQL database.
ExecuteScalar	Overloaded. Execute a single command against a MySQL database.
UpdateDataSet	Updates the given table with data from the given DataSet

Public Instance Methods

Equals(inherited from Object)	Determines whether the specified Object is equal to the current Object.
GetHashCode(inherited from Object)	Serves as a hash function for a particular type. GetHashCode is suitable for use in hashing algorithms and data structures like a hash table.
GetType(inherited from Object)	Gets the Type of the current instance.
ToString(inherited from Object)	Returns a String that represents the current Object.

See Also[MySqlHelper Class](#) , [MySql.Data.MySqlClient Namespace](#)25.2.4.1.5.1.1. [MySqlHelper.ExecuteDataRow Method](#)

Executes a single SQL command and returns the first row of the resultset. A new MySqlConnection object is created, opened, and closed during this method.

Syntax: Visual Basic

```
Public Shared Function ExecuteDataRow( _
    ByVal connectionString As String, _
    ByVal commandText As String, _
    ParamArray parms As MySqlParameter() _
) As DataRow
```

Syntax: C#

```
public static DataRow ExecuteDataRow(
    string connectionString,
```

```
stringcommandText,  
    params MySqlParameter[]parms  
);
```

Parameters

- `connectionString`: Settings to be used for the connection
- `commandText`: Command to execute
- `parms`: Parameters to use for the command

Return Value

DataRow containing the first row of the resultset

See Also

[MySqlHelper Class](#) , [MySql.Data.MySqlClient Namespace](#)

25.2.4.1.5.1.2. ExecuteDataset Method

Executes a single SQL command and returns the resultset in a DataSet. The state of the [MySqlConnection](#) object remains unchanged after execution of this method.

Overload List

Executes a single SQL command and returns the resultset in a DataSet. The state of the [MySqlConnection](#) object remains unchanged after execution of this method.

- `public static DataSet ExecuteDataset(MySqlConnection,string);`

Executes a single SQL command and returns the resultset in a DataSet. The state of the [MySqlConnection](#) object remains unchanged after execution of this method.

- `public static DataSet ExecuteDataset(MySqlConnection,string,params MySqlParameter[]);`

Executes a single SQL command and returns the resultset in a DataSet. A new MySqlConnection object is created, opened, and closed during this method.

- `public static DataSet ExecuteDataset(string,string);`

Executes a single SQL command and returns the resultset in a DataSet. A new MySqlConnection object is created, opened, and closed during this method.

- `public static DataSet ExecuteDataset(string,string,params MySqlParameter[]);`

See Also

[MySqlHelper Class](#) , [MySql.Data.MySqlClient Namespace](#)

25.2.4.1.5.1.2.1. MySqlConnection.ExecuteDataset Method (MySqlConnection, String)

Executes a single SQL command and returns the resultset in a DataSet. The state of the [MySqlConnection](#) object remains unchanged after execution of this method.

Syntax: Visual Basic

```
Overloads Public Shared Function ExecuteDataset( _  
    ByVal connection As MySqlConnection, _  
    ByVal commandText As String _  
) As DataSet
```

Syntax: C#

```
public static DataSet ExecuteDataset(  
    MySqlConnection connection,  
    string commandText  
);
```

Parameters

- `connection`: [MySqlConnection](#) object to use
- `commandText`: Command to execute

Return Value

DataSet containing the resultset

See Also

[MySqlHelper Class](#) , [MySql.Data.MySqlClient Namespace](#) , [MySqlHelper.ExecuteDataset Overload List](#)

25.2.4.1.5.1.2.2. MySqlConnection.ExecuteDataset Method (MySqlConnection, String, MySqlParameter[])

Executes a single SQL command and returns the resultset in a DataSet. The state of the [MySqlConnection](#) object remains unchanged after execution of this method.

Syntax: Visual Basic

```
Overloads Public Shared Function ExecuteDataset( _  
    ByVal connection As MySqlConnection, _  
    ByVal commandText As String, _  
    ParamArray commandParameters As MySqlParameter() _  
) As DataSet
```

Syntax: C#

```
public static DataSet ExecuteDataset(  
    MySqlConnection connection,  
    string commandText,  
    params MySqlParameter[] commandParameters  
);
```

Parameters

- `connection`: [MySqlConnection](#) object to use

- `commandText`: Command to execute
- `commandParameters`: Parameters to use for the command

Return Value

DataSet containing the resultset

See Also

[MySQLHelper Class](#) , [MySQL.Data.MySqlClient Namespace](#) , [MySQLHelper.ExecuteDataset Overload List](#)

25.2.4.1.5.1.2.3. MySQLHelper.ExecuteDataset Method (String, String)

Executes a single SQL command and returns the resultset in a DataSet. A new MySqlConnection object is created, opened, and closed during this method.

Syntax: Visual Basic

```
Overloads Public Shared Function ExecuteDataset( _  
    ByVal connectionString As String, _  
    ByVal commandText As String _  
) As DataSet
```

Syntax: C#

```
public static DataSet ExecuteDataset(  
    string connectionString,  
    string commandText  
);
```

Parameters

- `connectionString`: Settings to be used for the connection
- `commandText`: Command to execute

Return Value

DataSet containing the resultset

See Also

[MySQLHelper Class](#) , [MySQL.Data.MySqlClient Namespace](#) , [MySQLHelper.ExecuteDataset Overload List](#)

25.2.4.1.5.1.2.4. MySQLHelper.ExecuteDataset Method (String, String, MySqlParameter[])

Executes a single SQL command and returns the resultset in a DataSet. A new MySqlConnection object is created, opened, and closed during this method.

Syntax: Visual Basic

```
Overloads Public Shared Function ExecuteDataset( _  
    ByVal connectionString As String, _  
    ByVal commandText As String, _  
    ParamArray commandParameters As MySqlParameter() _  
) As DataSet
```

Syntax: C#

```
public static DataSet ExecuteDataset(
    string connectionString,
    string commandText,
    params MySqlParameter[] commandParameters
);
```

Parameters

- `connectionString`: Settings to be used for the connection
- `commandText`: Command to execute
- `commandParameters`: Parameters to use for the command

Return Value

DataSet containing the resultset

See Also

[MySqlHelper Class](#) , [MySql.Data.MySqlClient Namespace](#) , [MySqlHelper.ExecuteDataset Overload List](#)

25.2.4.1.5.1.3. ExecuteNonQuery Method

Executes a single command against a MySQL database. The [MySqlConnection](#) is assumed to be open when the method is called and remains open after the method completes.

Overload List

Executes a single command against a MySQL database. The [MySqlConnection](#) is assumed to be open when the method is called and remains open after the method completes.

- `public static int ExecuteNonQuery(MySqlConnection, string, params MySqlParameter[]);`

Executes a single command against a MySQL database. A new [MySqlConnection](#) is created using the [ConnectionString](#) given.

- `public static int ExecuteNonQuery(string, string, params MySqlParameter[]);`

See Also

[MySqlHelper Class](#) , [MySql.Data.MySqlClient Namespace](#)

25.2.4.1.5.1.3.1. MySqlHelper.ExecuteNonQuery Method (MySqlConnection, String, MySqlParameter[])

Executes a single command against a MySQL database. The [MySqlConnection](#) is assumed to be open when the method is called and remains open after the method completes.

Syntax: Visual Basic

```
Overloads Public Shared Function ExecuteNonQuery( _
    ByVal connection As MySqlConnection, _
    ByVal commandText As String, _
```

```
ParamArray commandParameters As MySqlParameter() _
) As Integer
```

Syntax: C#

```
public static int ExecuteNonQuery(
    MySqlConnection connection,
    string commandText,
    params MySqlParameter[] commandParameters
);
```

Parameters

- **connection**: [MySqlConnection](#) object to use
- **commandText**: SQL command to be executed
- **commandParameters**: Array of [MySqlParameter](#) objects to use with the command.

Return Value**See Also**

[MySqlHelper Class](#) , [MySql.Data.MySqlClient Namespace](#) , [MySqlHelper.ExecuteNonQuery Overload List](#)

25.2.4.1.5.1.3.2. MySqlHelper.ExecuteNonQuery Method (String, String, MySqlParameter[])

Executes a single command against a MySQL database. A new [MySqlConnection](#) is created using the [ConnectionString](#) given.

Syntax: Visual Basic

```
Overloads Public Shared Function ExecuteNonQuery( _
    ByVal connectionString As String, _
    ByVal commandText As String, _
    ParamArray parms As MySqlParameter() _
) As Integer
```

Syntax: C#

```
public static int ExecuteNonQuery(
    string connectionString,
    string commandText,
    params MySqlParameter[] parms
);
```

Parameters

- **connectionString**: [ConnectionString](#) to use
- **commandText**: SQL command to be executed
- **parms**: Array of [MySqlParameter](#) objects to use with the command.

Return Value**See Also**

[MySQLHelper Class](#) , [MySQL.Data.MySqlClient Namespace](#) , [MySQLHelper.ExecuteNonQuery Overload List](#)

25.2.4.1.5.1.4. ExecuteReader Method

Executes a single command against a MySQL database.

Overload List

Executes a single command against a MySQL database.

- `public static MySqlDataReader ExecuteReader(string,string);`

Executes a single command against a MySQL database.

- `public static MySqlDataReader ExecuteReader(string,string,params MySqlParameter[]);`

See Also

[MySQLHelper Class](#) , [MySQL.Data.MySqlClient Namespace](#)

25.2.4.1.5.1.4.1. MySQLHelper.ExecuteReader Method (String, String)

Executes a single command against a MySQL database.

Syntax: Visual Basic

```
Overloads Public Shared Function ExecuteReader( _  
    ByVal connectionString As String, _  
    ByVal commandText As String _  
) As MySqlDataReader
```

Syntax: C#

```
public static MySqlDataReader ExecuteReader(  
    stringconnectionString,  
    stringcommandText  
);
```

Parameters

- `connectionString`: Settings to use for this command
- `commandText`: Command text to use

Return Value

[MySqlDataReader](#) object ready to read the results of the command

See Also

[MySQLHelper Class](#) , [MySQL.Data.MySqlClient Namespace](#) , [MySQLHelper.ExecuteReader Overload List](#)

25.2.4.1.5.1.4.2. MySQLHelper.ExecuteReader Method (String, String, MySqlParameter[])

Executes a single command against a MySQL database.

Syntax: Visual Basic

```
Overloads Public Shared Function ExecuteReader( _  
    ByVal connectionString As String, _  
    ByVal commandText As String, _  
    ParamArray commandParameters As MySqlParameter() _  
) As MySqlDataReader
```

Syntax: C#

```
public static MySqlDataReader ExecuteReader(  
    string connectionString,  
    string commandText,  
    params MySqlParameter[] commandParameters  
);
```

Parameters

- `connectionString`: Settings to use for this command
- `commandText`: Command text to use
- `commandParameters`: Array of [MySqlParameter](#) objects to use with the command

Return Value

[MySqlDataReader](#) object ready to read the results of the command

See Also

[MySqlHelper Class](#) , [MySql.Data.MySqlClient Namespace](#) , [MySqlHelper.ExecuteReader Overload List](#)

25.2.4.1.5.1.5. ExecuteScalar Method

Execute a single command against a MySQL database.

Overload List

Execute a single command against a MySQL database.

- [public static object ExecuteScalar\(MySqlConnection,string\);](#)

Execute a single command against a MySQL database.

- [public static object ExecuteScalar\(MySqlConnection,string,params MySqlParameter\[\]\);](#)

Execute a single command against a MySQL database.

- [public static object ExecuteScalar\(string,string\);](#)

Execute a single command against a MySQL database.

- [public static object ExecuteScalar\(string,string,params MySqlParameter\[\]\);](#)

See Also

[MySqlHelper Class](#) , [MySql.Data.MySqlClient Namespace](#)

25.2.4.1.5.1.5.1. MySqlHelper.ExecuteScalar Method (MySqlConnection, String)

Execute a single command against a MySQL database.

Syntax: Visual Basic

```
Overloads Public Shared Function ExecuteScalar( _
    ByVal connection As MySqlConnection, _
    ByVal commandText As String _
) As Object
```

Syntax: C#

```
public static object ExecuteScalar(
    MySqlConnectionconnection,
    stringcommandText
);
```

Parameters

- **connection**: [MySqlConnection](#) object to use
- **commandText**: Command text to use for the command

Return Value

The first column of the first row in the result set, or a null reference if the result set is empty.

See Also

[MySqlHelper Class](#) , [MySql.Data.MySqlClient Namespace](#) , [MySqlHelper.ExecuteScalar Overload List](#)

25.2.4.1.5.1.5.2. MySqlHelper.ExecuteScalar Method (MySqlConnection, String, MySqlParameter[])

Execute a single command against a MySQL database.

Syntax: Visual Basic

```
Overloads Public Shared Function ExecuteScalar( _
    ByVal connection As MySqlConnection, _
    ByVal commandText As String, _
    ParamArray commandParameters As MySqlParameter() _
) As Object
```

Syntax: C#

```
public static object ExecuteScalar(
    MySqlConnectionconnection,
    stringcommandText,
    params MySqlParameter[]commandParameters
);
```

Parameters

- `connection`: [MySQLConnection](#) object to use
- `commandText`: Command text to use for the command
- `commandParameters`: Parameters to use for the command

Return Value

The first column of the first row in the result set, or a null reference if the result set is empty.

See Also

[MySQLHelper Class](#) , [MySQL.Data.MySqlClient Namespace](#) , [MySQLHelper.ExecuteScalar Overload List](#)

25.2.4.1.5.1.5.3. MySQLHelper.ExecuteScalar Method (String, String)

Execute a single command against a MySQL database.

Syntax: Visual Basic

```
Overloads Public Shared Function ExecuteScalar( _
    ByVal connectionString As String, _
    ByVal commandText As String _
) As Object
```

Syntax: C#

```
public static object ExecuteScalar(
    string connectionString,
    string commandText
);
```

Parameters
